SLEEPING SICKNESS AND NAGANA

ELSEWHERE in this issue of *Nature* (p. 89), we are publishing a very brief statement under the names of the late Dr. F. H. S. Curd and Dr. D. G. Davey, of Imperial Chemical Industries, Ltd., relating to the new drug 'Antrycide'. This statement must be regarded as the scientific background of the Press conference held jointly by the Colonial Office and Imperial Chemical Industries, Ltd., on December 29.

From the work which has already been done with 'Antrycide', it appears to be of great value in the prophylaxis and cure of trypanosome diseases of cattle ; further, it has focused attention on one side of a very large and complex problem. In nearly all parts of tropical Africa tsetse flies (*Glossina*, of several species) prevail. These insects are the principal transmitters of the trypanosome infections of cattle, known generally as nagana, and the sole transmitters of human trypanosomiasis or sleeping sickness. The presence of tsetse flies generally renders it impossible to maintain cattle, and this prevents the development of mixed farming, or production of beef, and means that cultivation must be done by the human hand. There can be little doubt, also, that tsetse flies have presented a great barrier to transport, and therefore to the penetration of Africa by Arabs and Europeans. The problem is being attacked, and parts of it have been solved, by medical and veterinary workers, and by protozoologists and entomologists.

The entomological attack on tsetse has been by studying and attempting to alter the environment ; this has met with considerable success under certain conditions, particularly where the destruction of thickets has abolished the permanent haunts and breeding-places of some species of these flies. The method is now beginning to prove successful even against *Glossina morsitans*, a very widely distributed species and one which was particularly difficult to control. Some excellent ecology has been associated with this work : among other things, a method has been developed (based on marking individual flies, and determining the proportion of them in samples afterwards captured) of estimating the actual number of tsetse in an area. This quantitative work is of great value in studying the effect of bush-clearing on the fly community.

One way of attacking thicket and altering the environment so that it becomes unfavourable to the fly is by human settlement and cultivation. The method requires a good knowledge of the ecology of the African peasant, and a study of his agricultural methods. There are now areas in both east and west Africa in which large numbers of Africans, with their cattle, are living in health, where even a few years ago this was impossible. Another line of attack is by the destruction of game animals, a method which has proved to be successful against *G. morsitans* (though not against certain other species of tsetse which have sources of food other than the game). The scientific justification is that the trypanosomes which attack cattle live in the blood of many sorts of game animals, which constitute a reservoir. Moreover, certain sorts of tsetse are so dependent on ungulates for food, that if game is destroyed (cattle being absent) the tsetse die out. Game destruction has produced valuable results in Southern Rhodesia, where it seems that some ten thousand square miles have been cleared of tsetse at the low figure of about £18 to the square mile. It should not, however, be thought that other tsetse problems can be dealt with in the same way. The destruction of game, repugnant but necessary, entails also the duty and indeed the necessity of making reserves where stocks of the wild animals may be maintained for all time, completely segregated from cattle.

The use of insecticides is under study, and may prove valuable at least for special problems and in limited areas. The South Africans have had great success with a D.D.T. smoke, put down from the air, over a small game reserve. Nevertheless, it can scarcely be expected that insecticides will be a practical or economic way of tackling a fly-belt of thousands of square miles of unoccupied wilderness.

The trypanosome diseases of man, generally known as sleeping sickness, have been curable for many years. It is now customary for itinerant teams, mainly African, to visit villages where outbreaks occur, giving immediate treatment by injection, and there is seldom need to take the patients into hospital. Provided the work is thorough and the early cases are diagnosed and treated, this method reduces the likelihood of fresh infections, so that Health Departments are no longer afraid of epidemics and are steadily reducing the incidence of this disease. This represents an immense advance, the importance of which is not generally realized: for early in the present century, sleeping sickness, which was then incurable, was credited with the deaths of two-thirds of a population of about three hundred thousand in one part of Uganda, and was a frequent cause of depopulation in many parts of Africa. Certain drugs are also of great interest because they appear to give protection for some months, a factor which is of great value where men are exposed to particular risk.

The veterinary problem was until recently extremely difficult. The disease known generally as nagana can be caused by several species of trypanosome which react differently to drugs. One of these in particular, *Trypanosoma congolense*, is extremely dangerous to cattle and has been difficult to cure. Owing to the curative and protective effects of 'Antrycide', it seems likely that it will soon be possible to keep cattle in areas at present occupied by tsetse, or at least to move them through a fly belt on their way to market. A moment's reflexion will make it clear that the problem of treating large numbers of cattle which have never been handled and which range over large unfenced areas must be very difficult: and their owners, who are nomadic in many places, will have to be approached with understanding. Nevertheless, a way has been opened for attacking the central problem, and it must be expected that incidental difficulties will in due course be overcome.

The whole subject of trypanosomiasis, fascinating in its complexity, has been recently dealt with in a series of reports written by experts and published by the Colonial Office* The impression th

GEOLOGIST AND GEOGRAPHER IN EARLY NEW ZEALAND

e Life and Times of Sir Julius von Haast

plorer, Geologist, Museum Builder. By H. F. von ast. Pp. xxii + 1142 + 25 plates. (Wellington, : The Author, 41 Salamanca Road, 1948.)

N December 21, 1858, Julius Haast, a thirty-six- ar-old German, arrived in Auckland, New twenty-nine years later Sir Julius von M.G., F.R.S., died at Christchurch as one known men of science in the southern

of these twenty-nine years is one of n the point of view of the scientific, l civic development of New Zealand in lf-century of its existence as a self-govern- and tells of the advance of an unknown inence against the handicap of foreign birth at and against the constant opposition of on, who could see in geology no advantage unsurveyed and largely unexplored country, ed immediately to new goldfields or payable s.

Haast was not trained to be a geologist, he took some lectures in geology at the ty of Bonn, where he studied without ng. When he left the University he spent rs travelling in Europe engaged in some ed form of business activity, and in 1858 he a commission from an English firm of ship- o visit New Zealand to report upon the of a large-scale scheme for German emigra- hat colony.

e day following Haast's arrival in Auckland trian frigate *Novara* entered the port. The was on a scientific cruise around the world ied a large staff of scientific men, among them nd Hochstetter, then a member of the n Geological Survey, and later renowned as aniser and first director-general of the Imperial l History Museum in Vienna. Haast, feeling ely in a strange land, was delighted to meet llow countrymen, and soon struck up what to be a lifelong friendship with Hochstetter. he request of the New Zealand Government, etter was detached from the expedition in o make a survey of the mineral and other es of the colony. For nine months he toured provinces of Auckland and Nelson, and took t along with him. This was the turning point st's life, for under the influence of Hochstetter's siasm and expert knowledge, geology, which usly had only been Haast's hobby, became the nterest in his life. Business and emigration no interested him; he decided to be a geologist. y be remarked here that one of the marvels of s career is that, except for the nine months he with Hochstetter, he had no real training in gy. He learnt modern geology from text-books and kept himself up to date by scientific journals, all purchased from his own small salary—there were no scientific libraries in New Zealand in those days.

Six months after the departure of Hochstetter, aast made an offer to the Provincial Government of anterbury to make for it a topographical and ological survey of that Province. The offer was epted, but no formal agreement was drawn up; d what was intended to be an undertaking of two or three years duration became a major operation extending over a decade, in the course of which Haast ascended every Canterbury river to its source and mapped all the principal peaks of the Southern Alps, their outrunning spurs, their snowfields, glaciers and watercourses.

Haast was not a shy man and took, or made, every opportunity of corresponding with all the best-known geologists, botanists, glaciologists and zoologists of Europe and America—among his numerous correspondents in Great Britain alone were Murchison, Lyell, Tyndall, Hooker, Ramsay, Huxley and Darwin. This, however, was not surprising, for he had much to tell them which they wished to know. Little of the geology of the southern hemisphere was then known, and so his geological survey of a considerable area of New Zealand was welcomed by geologists. In his survey he found evidence of a former great expansion of the glaciers of the Southern Alps comparable with the extension in the European Alps during the Great Ice Age; this, with its implications of world-wide glaciation, was of intense interest to geographers and glaciologists. When a few years earlier Owen had described, on the evidence of a single bone, a gigantic wingless bird which had recently lived in New Zealand, the interest excited extended far beyond scientific circles. Subsequent discovery of further bones of the same species confirmed Owen, and naturally every zoologist and museum director desired to possess at least one moa bone. Haast discovered not single bones but literally heaps of them, so that he could construct complete skeletons, and these he offered to his correspondents in return for museum specimens which he himself desired. In his mapping of the Southern Alps many new peaks, glaciers and rivers required names; in the absence of native names Haast "commemorated, as in a mighty cenotaph of Nature, the great scientists of the nineteenth century, and so it comes about that we find upon the map of New Zealand the names of the world's representative scientists from all parts of the world". Practically every one of Haast's scientific correspondents was commemorated in this way, and one of his greatest pleasures was to inform a correspondent of the fact. There is no wonder that within ten years of becoming a geologist, Haast's name was well known in scientific circles.

We cannot here follow Haast's subsequent career in detail; but the book tells us how he took a leading part in establishing in the young colony new intellectual activities, especially in art, music and education; how he established and became director of the Canterbury Museum and made it by far the finest museum south of the equator; how he was sent to England in charge of the New Zealand exhibit at the Colonial and Indian Exhibition held in London in 1886 under the presidency of the Prince of Wales, and how his energy in organising the New Zealand Court so impressed the Prince that he personally suggested to Queen Victoria that she should invest Haast with the K.C.M.G.; and how Haast died within a month of his return from London, full of honours and the respect of the citizens of Christchurch, who had been so slow to recognize his abilities twenty years earlier.

The book is interestingly written by his son and will attract both scientific and non-scientific readers; it would, however, have been easier to read with enjoyment if it had not run to half a million words and had been less than four pounds in weight.

GEORGE C. SIMPSON

DAVID DOUGLAS: BOTANIST AND TRAVELLER

Douglas of the Fir

A Biography of David Douglas, Botanist. By Athelstan George Harvey. Pp. x+290+6 plates. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1947.) 22*s.* net.

When a taxonomist describes some hitherto unrecognized form of life he is free to select what attributes he likes as the basis of the name by which the new organism shall be known—the specific name only, if he assigns it to an already established genus, and both generic and specific if it is different enough to warrant the setting up of a new genus. The name, in fact, reflects only the view of one individual as to what is appropriate, and it must be admitted that where such a name perpetuates the memory of a person, the person in question has often had very little real claim to such distinction. When, however, the common designation for a plant or animal includes a person's name, one expects to find that the person has had much to do with making the organism widely known and has probably also taken an active part in the general field of exploration and distribution. Douglas's name is attached to one of the finest and most important trees of the world, and one is ready to be interested in learning more about him. It was this interest that led the author of the book under review to undertake the collection of all traceable information about this enthusiastic exploring botanist and collector, who did so much some hundred and twenty years ago to discover and introduce to Europe the wealth of trees and plants of western America, particularly the Columbia basin.

David Douglas, whose Pacific Coast journeys were made between 1824 and his tragic death in Hawaii in 1834, was methodical in his habits, at least to the extent of keeping a diary, the surviving parts of which were published in 1914, extracts having already appeared in 1836 (through W. J. Hooker). His botanical enthusiasm, his pertinacity—doubly apparent when extra handicaps such as failing eyesight, an injured limb, or malnutrition had to be overcome—and his faculty for getting on with the local Indians, were his outstanding characteristics, and they brought him in a relatively few years from a humble origin to general recognition as the most successful man in Europe in his chosen field. His rugged individualism was an important factor in his success on his travels, but got him into difficulties at home; he must at times have been most aggravating to his companions, always wanting to do something different, usually something more difficult and more exhausting than necessary, such as walking when one could ride, or forcing a way through trailless riverside vegetation when one had a boat. His pertinacity and physical endurance never showed better than on the occasions when in fording rivers he lost the fruits of months of work, or equally in the way he carried on his back his specimens, dead and alive—for he was almost equally keen on animals, birds and rocks—sometimes hundreds of miles, perhaps only to lose them in the end to a predatory dog or rat.

To Douglas, the tree we know as his 'fir', or *Pseudotsuga taxifolia,* was a pine—to this day the timber is 'Oregon pine'—and pines were, perhaps, his greatest enthusiasm. His ultimately successful search after the sugar pine (*P. lambertiana*) is itself a botanical epic, and it would perhaps be more fitting if his name were associated with it rather than the *Pseudotsuga.* He also introduced another pine, which from a restricted distribution in Monterey, California, is now among the most important in forestry, namely, *P. insignis,* as well as *P. ponderosa. P. monticola* and *P. sabiana* were also discovered or introduced to Europe by him, not to mention Sitka spruce (as *P. menziesii*), *Abies nobilis* and *A. amabalis.* Incidentally, the Douglas fir was discovered by Capt. Vancouver in 1792 and described by Lambert in 1803 as *Pinus taxifolia.* Lambert, however, had no cones until Douglas brought him some, and then he described it as *P. douglasii.*

The biography is illustrated by portraits of David Douglas, his father, and W. J. Hooker, and five good photographs of the country he explored. The sketch maps could be a good deal better. There is a selected list of Douglas's introductions. The author had a quite exceptionally interesting subject for his study, and the story has not lost in the telling.

H. G. Champion

'POPULAR' ANIMAL BOOKS

Animal Wonderland

Essays in Natural History. By Frank W. Lane. Pp. xii + 232 + 80 plates. (London: Country Life, Ltd., 1948.) 15*s.* net.

Animals Alive

By Austin H. Clark. Pp. viii + 472. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1948.) 22*s.* net.

The two books "Animal Wonderland" and "Animals Alive", the first by Frank W. Lane and the second by Austin H. Clark, are not only alike in their titles but also in the wide field they cover. Both are of the type termed 'popular', that is to say they present the layman with a variety of interesting facts concerning creatures great and small in non-technical language. Dr. Clark sets out to survey the animal kingdom from mammals (including man) to insects, spiders and more lowly beings. He points out that some of the smallest creatures are not the least in importance to us, for example, such domesticated insects as the honeybee and the silkworm. His book is very readable, and full of reliable information.

Mr. Lane's book is also readable and entertaining. It is a collection of remarkable things concerning animals, culled from sources far and near. He begins with the "split second in Nature", and cites such facts as "a human sneeze rarely lasts more than a tenth of a second, and some of the droplets in a hearty sneeze are shot out at a speed of one hundred and fifty-two feet per second, or just over one hundred miles per hour". He goes on to such topics as "Accidental Death", one of the illustrations to which shows a pike choked by trying to swallow another pike not much smaller than itself; "Have Animals a Time Sense ?" and many others; the last chapter being devoted to "A Species that was Saved", namely, the North American bison, which after being nearly exterminated by the recklessness of hunters has been nursed back into a safe position—Mr. Lane says the 1933 figures showed a population of 21,701 bison.

Frances Pitt

Mother Earth

A Popular Account of the Earth in the Light of Recent Knowledge. By Dr. T. A. Ryder. Pp. 184. (London: Hutchinson's Scientific and Technical Publications, 1947.) 15*s.* net.

THIS book deals with earth sciences other than their applied aspects. It gives a general account of the origin, nature and features of the earth, its hydrosphere and atmosphere and a brief account of the solar system. Inevitably it covers much of the main field of text-books of physical geology and geography. No specialized knowledge is assumed, but technical terms have crept in here and there. It is designed to bring a wider appreciation of the more striking aspects of recent research, and is generally a well-balanced presentation.

There is a regrettably large number of misstatements which detracts from the merits of the book. The lithosphere is described as the discontinuous granitic layer, absent beneath the oceans, in one place (p. 29), and elsewhere as including a lower, basaltic portion (p. 35). Metamorphic rocks are described without reference to thermal effect (p. 30). Ammonites are not "almost invariably" an indication of Jurassic age (p. 32), nor do clays consist mainly of flakes of "alumina" (p. 37). The Yorkshire and Lincolnshire Wolds are not composed of Jurassic rocks (p. 46), nor are Mauna Loa and Mauna Kea in the Philippines! The repeated reference to "palæographic" meaning 'palæogeographic' maps is unfortunate. The summary on p. 114 is no summary at all. "Ocean deep" in one place refers to the ocean basins, and in another to the oceanic troughs, and so on. From this far from complete catalogue, and other minor errors in proof reading, it will be evident that the book must fall short seriously of the excellent intentions of the author. Nevertheless, it combines an outline of a wide range of interesting developments written for the layman and not readily obtainable in this form.

Life: its Nature and Origin

By Jerome Alexander. Pp. ix+291. (New York: Reinhold Publishing Corporation; London: Chapman and Hall, Ltd., 1948.) 30*s.* net.

THIS is an example of a 'semi-popular' book on science of a kind which seems to be characteristic of the United States. The field covered is adumbrated in the first two sentences of the preface: "The mystery of life, so long unsolved, and by many regarded as beyond human understanding, has been slowly revealing itself in the light of scientific investigation. The purpose of this book is to present in coherent order sufficient facts regarding material biological phenomena to show that life is dominated by *catalysis*—the direction of chemical change by surface areas of specific structure and efficiency." In pursuit of this aim the author wanders—alas, not very coherently—over a vast area which includes almost every topic from nuclear physics to modern psychology. He quotes rather extensively from detailed original papers, and certainly parades before his readers a huge and heterogeneous assemblage of facts and suppositions. But throughout most of the book, the theoretical structure which connects, say, a paragraph on the determination of the different castes in Hymenoptera with one on the recognition by rattlesnakes of their reptilian enemies amounts to no more than a repetition of the sentiment that here we have catalysis at work again. The book should have been pruned to half its size; its argument, which is by no means novel but probably worth stating clearly for a popular audience, would then have emerged much more forcibly.

C. H. WADDINGTON

Synthetische Methoden der organischen Chemie

Von W. Theilheimer. Repertorium 2. Pp. viii+309. (Basel and New York: S. Karger, 1948.) 35 Swiss francs.

ORGANIC chemists will welcome the appearance of this second volume of "Theilheimer", in which are to be found references to most of the more important synthetic reactions, old and new, described in the European literature for 1944–46. This limitation to European sources is due solely to war conditions and is to be remedied in a later volume in which the American literature, *inter alia*, will be dealt with. In all, 845 reactions are cited, and it is interesting to note that half are from the *Journal of the Chemical Society* and one-third from *Helvetica Chimica Acta*. The reactions are arranged according to a system which is simple and clearly explained; a good alphabetical index, which also covers the first volume, aids in the search for methods suitable for the synthesis of given types of compound. The information given under each reaction comprises the reference, supplemented if necessary by references to earlier key papers, and an outline of the experimental details.

The book is well produced, convenient in size and stoutly bound, an important feature in a volume likely to be consulted so frequently. There is little doubt that "Theilheimer" has come to stay as an important adjunct to "Beilstein" in the literature of organic chemistry.

H. N. RYDON

Dipole Moments

Their Measurement and Application in Chemistry. By Prof. R. J. W. Le Fèvre. (Methuen's Monographs on Physical Subjects.) Second edition, revised and reset. Pp. v+118. (London: Methuen and Co., Ltd., 1948.) 5*s.* net.

DR. LE FÈVRE has written a very lucid and useful little book that amply covers the subject-matter, as outlined by the title. The theory in Chapter 1 is clear and fairly simply presented, except perhaps in Debye's derivation of orientation polarization (leading to the Langevin function), where the mathematics is abbreviated and the Maxwell–Boltzmann distribution is used but not quoted as such; however, this compression may be intentional in such a slim volume. Chapter 2 gives all the necessary information required for the measurement of dielectric constants by a variety of methods and the calculation of results: the main criticism that might be offered here is that some of the instructions are too detailed; for example, in quoting the valve numbers of the author's electronic apparatus. Chapters 3, 5 and 6 on solvent effects, intra-molecular rotations and anomalous dipole moments respectively are all very comprehensive, but to the more general chemist the most interesting section of the book is Chapter 4. In this part a wide survey is made of the application of dipole moments to the solution of structural problems, and a large number of actual examples and papers are quoted and discussed.

Finally, this book is well indexed and full of references, and it certainly lives up to the high standard that we have come to expect of this series of little monographs.

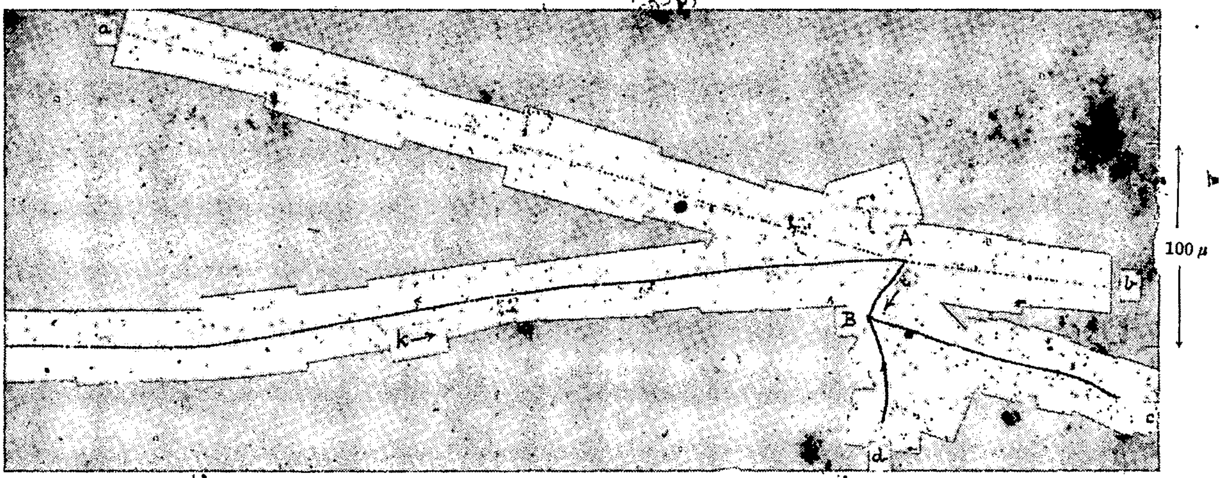
OBSERVATIONS WITH ELECTRON-SENSITIVE PLATES EXPOSED TO COSMIC RADIATION*

By Miss R. BROWN, U. CAMERINI, P. H. FOWLER, H. MUIRHEAD
and Prof. C. F. POWELL
H. H. Wills Physical Laboratory, University of Bristol

and D. M. RITSON
Clarendon Laboratory, Oxford

PART 2. FURTHER EVIDENCE FOR THE EXISTENCE OF UNSTABLE CHARGED PARTICLES, OF MASS ~ 1,000 m_e, AND OBSERVATIONS ON THEIR MODE OF DECAY

ONE of the first events found in the examination of electron-sensitive plates exposed at the Jungfraujoch is represented in the mosaic of photomicrographs shown in Fig. 8. There are two centres, *A* and *B*, from which the tracks of charged particles diverge, and these are joined by a common track, *t*. Because of the short duration of the exposure, and the small number of disintegrations occurring in the plate, the chance that the observation corresponds to a fortuitous juxtaposition of the tracks of unrelated events is very small—of the order 1 in 10^7. It is therefore reasonable to exclude it as a serious possibility. Further observations in support of this assumption are presented in a later paragraph.



Observer: Mrs. W. J. van der Merwe

Fig. 8

An inspection of the track *k* shows that the particle producing it approached the centre of disintegration *A*. The range of the particle in the emulsion exceeds 3,000 μ, and there is continuous increase in the grain-density along the track in approaching *A*. Near *A*, the grain-density is indistinguishable from that of particles of charge *e*, recorded in the same plate, near the end of their range.

The evidence for the direction of motion of the particle based on grain-counts is supported by observations on the small-angle deviations in the track due to Coulomb scattering. These deviations are most frequent near *A*, and the scattering is less marked at points remote from it.

From these observations, it is reasonable to conclude that the particle *k* approached the point *A*; that it carried the elementary electronic charge; and that it had reached, or was near, the end of its range at the point *A*. We therefore assume that the particle *k* initiated the train of events represented by the tracks radiating from *A* and *B*. It follows that the particle producing track *t* originated in star *A*, and produced the disintegration *B*. In order to analyse the event, we first attempted to determine the mass of the particle *k*.

Mass Determinations by Grain-Counts

About a year ago, experiments were made in this Laboratory to determine the ratio, m_π/m_μ, of the masses of π- and μ-mesons, by the method of grain-counting[5], and by studying the small-angle scattering of the particles in their passage through the emulsion[4]. The values obtained by the two methods were $m_\pi/m_\mu = 1\cdot65 \pm 0\cdot11$, and $m_\pi/m_\mu = 1\cdot35 \pm 0\cdot10$*, respectively. Recent experiments at Berkeley[6] suggest that the true value is $1\cdot33 \pm 0\cdot02$, a result which throws serious doubt on the reliability of the method based on grain-counts. Because of the advantage of this method, and of the important conclusions which have been based on it, experiments were made to determine the conditions in which reliable results can be obtained.

In the first experiments[5], the two most serious experimental difficulties arose from the fading of the latent image and from the variation of the degree of development with depth. This made it necessary to

---

* Continued from page 51.

* For the following reasons, the limits of error quoted above, in the determination of m_π/m_μ by observations on scattering, are less than those given in ref. 4. Previously, values for the mass of the different types of mesons, classified phenomenologically, were given separately. It is now known, however, that at least the majority of the σ-mesons are π^--particles; and the ρ-mesons, μ^+- and μ^--particles. The different results can therefore be combined to give a value for m_π/m_μ with a greater statistical weight.

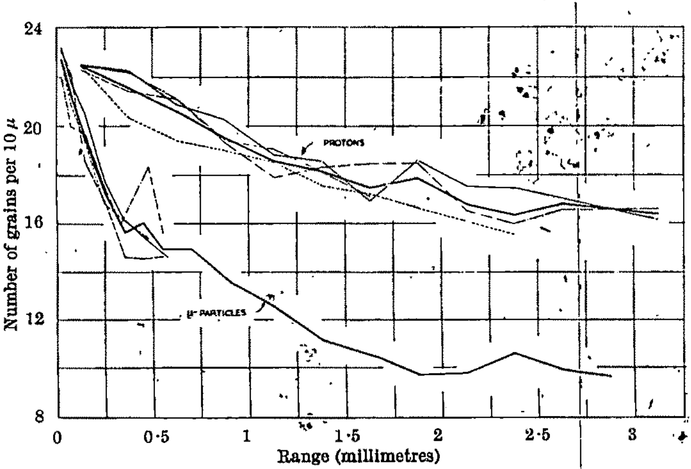


Fig. 9

work only with tracks formed contemporaneously; to compare the grain-density along the tracks of the π- and μ-mesons of the same pair. As a result, the tracks of the π-mesons available for measurement were, in most cases, shorter than 400 μ. In continuing the experiments, much more favourable conditions were obtained by using short exposures, so that the effects of fading were negligible; and by developing the plates by the method employed by Dilworth, Occhialini and Payne[7], which gives a nearly uniform degree of development with depth.

In the plates obtained by these methods, it is legitimate to compare the grain-density in the tracks of unrelated particles. Further, it is now known that at least the majority, and possibly all, the mesons which produce 'stars' are π^--particles[6,8]; and that most of the ρ-mesons are μ^+- and μ^--particles. In determining m_π and m_μ, we have therefore made measurements on the tracks of π^+- and π^--, μ^+- and μ^--particles, of length greater than 1,000 μ, comparing the results with those of similar measurements made on the tracks of protons. In these conditions, we have found $m_\pi/m_\mu = 1{\cdot}33 \pm 0{\cdot}05$. A detailed account of the observations will be published elsewhere; but, for the purpose of the present paper, it is sufficient to note that the results appear to be in good accord with those obtained by other methods. We conclude that, using the Ilford C2 emulsion in the new conditions, reliable information can be obtained.

We have seen that the conditions of uniform development and absence of fading have been achieved in the present experiments with the new Kodak emulsions, and we therefore attempted to measure the mass of particles by similar methods to those employed with the Ilford plates. The results obtained in observations on the tracks of four protons and four μ-particles, occurring in the same plate, are represented in Fig. 9. In this figure, the number of grains per unit length in the tracks is plotted for different values of the residual range; and the mean values, for tracks of the same type, are indicated by the full lines. The ratio of the masses of the two types of particles can be deduced by making a comparison of the values of the residual range at which the grain densities have the same value. The result thus obtained is $m_\mu = 220 \pm 20\ m_e$.

Using similar methods, we have made estimates of the mass of the particle, k, and the measurements are represented in Fig. 10. This figure shows the mean values of the grain-density in the tracks of the four μ-mesons and four protons, together with the corresponding results for the particle k. All the tracks under consideration occurred in the same plate.

Table 1 shows the values of the mass of the particle, k, as determined from these results, by making a comparison of the grain-density in the track of the particle with the mean curve for protons. The values thus obtained are all independent and the mean is $m_k = 1{,}080 \pm 160\ m_e$.

TABLE 1. Determination of the ratio, m_p/m_k, of the mass of a proton to that of particle, k, by grain-counting

	Individual independent values						
m_p/m_k	1·77	1·88	1·49	1·64	2·17	1·79	1·32
	1·71	1·66	1·27	1·69	2·13	1·55	

Mean value: 1·70; $m_k = 1{,}080 \pm 160\ m_e$

The limits of error given above have been deduced in the following manner: We have compared the grain-density in the tracks of the four individual protons with the mean curve for the same particles—(see Fig. 9)—and have thus obtained a number of independent values for the apparent mass of each of these particles. The distribution in these values allows us to calculate the 'probable error' associated with the mass as determined from the observations on any one track, expressed as a percentage of the apparent mass of the particle. It is then assumed that the 'probable' percentage error in the calculated mass of the particle k has the same value.

We have also determined the mass m_k by studying the small-angle scattering of the particle, by the methods recently described[4], and the result thus obtained is $m_k = 1{,}800 \pm 400\ m_e$. If the true mass of the particle is 1,080 m_e, the chance that the value obtained by observations on scattering shall be equal to, or greater than, 1,800 m_e is one in four. Because of the large statistical fluctuations associated with

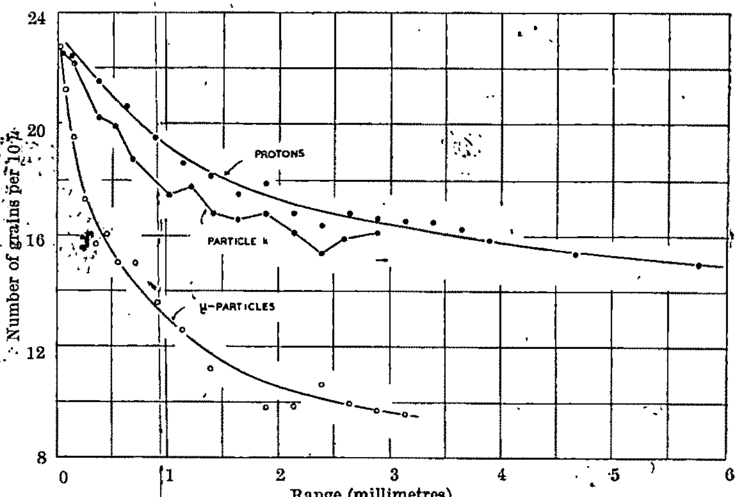

Fig. 10

the observations in the scattering experiments, we give more weight to the measurements by grain-counting. It appears certain, from these observations, that the true value of m_k lies between 700 and 1,800 m_e, and we think it highly probable that it is substantially less than that of the proton. Thus every individual point representing the grain-density in the track k, at a particular value of the residual range, lies below the corresponding points for each of the four protons.

Disintegration 'B'

The tracks, c and d, of the two particles emitted from point B are characteristic of protons or heavier particles, and we regard them as due to a disintegration produced by the particle t. This particle was frequently scattered in passing through the emulsion and was therefore of low velocity; and the evidence is consistent with the assumption that it had reached the end of its range at the point B.

The only known slow charged particle which is capable of producing a disintegration of the type represented by star B is a π^--particle[6,8]. We therefore assume that a negative meson of mass 286 m_e was created at the point A, and reached the end of its range to produce the disintegration B.

Transmutation 'A'

In order to interpret the transmutation A, we first made a detailed examination of the tracks of the emitted particles. Of the two tracks a and b, the former has a length in the emulsion of more than 2,000 μ, and ends in the surface, whereas b ends in the glass and is 116 μ long. The grain-densities in the two tracks are equal to within the limits defined by the statistical fluctuations. The average grain-density in the long track a is 49·0 grains per 100 μ; that is, 2·17 times the value characteristic of minimum ionization for a particle of charge e. Unless we admit the existence of fractional values of the electronic charge, we must conclude that the particles producing the tracks a and b both carried charges of magnitude e.

In order to determine the possible values for the energy of the particles producing tracks a and b, we have calculated the variation with energy of the specific ionization of a particle of charge e, from the formula of Halpern and Hall[9], assuming the atomic composition of the emulsion to be identical with that of the Ilford C2 plates. This formula is a modification of that of Bloch[10]; it applies to particles moving in a solid medium and gives results in good agreement with experiment for particles of low energy. The results are shown in Fig. 11, where the specific ionization is plotted as a function of the quantity E/m, where E is the energy and m the mass of the particle, both quantities being measured in MeV. From Fig. 11, we have determined the possible values of the energy of the particles, a, b, corresponding to the observed grain-density in the tracks, assuming them to be protons, π-mesons, μ-mesons or electrons. The resulting values are tabulated in Table 2.

TABLE 2. Values of the energy and momentum of the particle producing track a, as deduced from the observed grain-density and scattering, making various assumptions concerning the mass of the particle

Assumed particle		proton	π-meson	μ-meson	electron
Energy in MeV.	(a) below minimum ionization	235±95	37±13	27±11	0·13±0·05
	(b) above minimum ionization				> 1,000
Momentum MeV./c	(a) below minimum ionization	700±160	109±22	80±15	0·4±0·1
	(b) above minimum ionization				> 1,000
	(c) from scattering observations	245±40	113±18	100±16	68±11
	(d) from momentum balance	98±5	98±5	98±5	98±5

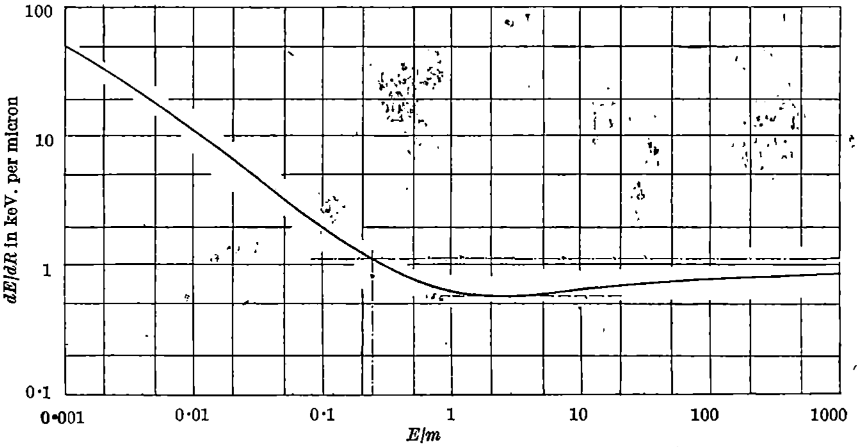

Fig. 11. Variation of the rate of loss of energy of a particle of charge |e| as a function of the quantity E/m, where E is the kinetic energy and m the mass of the particle, both quantities being measured in MeV.

There are two possible interpretations of the transmutation produced at A by the particle k. We can assume, either that the particle was captured by a nucleus, or that it decayed spontaneously. From the measured values of the mass of the particle, it would be possible, from the point of view of the conservation of mass and energy, to admit that, at the end of its range in the emulsion, it was captured by a nucleus and led to the ejection of two energetic protons and a π^--particle. It appears almost certain, however, that the release in a nucleus of such a large amount of energy would lead to the 'evaporation' of many nucleons, a process commonly observed in plates exposed to the cosmic radiation; and that two protons of great energy would be only two components of a 'many-pronged' star. (It may be noticed that we cannot assume that the particle k was captured by one of the rare nuclei of heavy hydrogen, present in the gelatine. In such an interaction, the algebraic sum of the charges on the two initial particles is 0 or $2e$, whereas that of the product particles is e or $3e$.) We shall see later that there are other objections to the hypothesis that the tracks a and b were produced by protons, or heavier nuclei of charge e.

It follows from the above considerations that if we are to describe the transmutation in terms of particles of which the existence is already established, we must attribute the tracks a and b either to electrons, to μ-mesons or to π-mesons. Considering the first of these possibilities, we must assume the electrons to have had an energy value greater than that corresponding to minimum ionization, namely, greater than 1,000 MeV.; for with the alternative lower value corresponding to the observed ionization, 300 keV., the particle would have had a range in the emulsion of only about 100 μ, and would have been frequently scattered. The assumption that the particles *a* and *b* were electrons is therefore inconsistent with the conservation of energy and can be rejected. We are left with the alternatives that the tracks were produced either by π- or by μ-mesons.

If the particles *a* and *b* were mesons, we must assume, in order to conserve mass-energy, that their kinetic energies were 27 MeV. or 37 MeV., respectively, in the case of μ- or π-mesons (see Fig. 11). In either case, it appears to be very difficult to reconcile the observations with the assumption that the particles were emitted as a consequence of the liberation in a nucleus of the energy corresponding to the rest-mass of particle *k*. We are therefore led to examine the possibility of explaining the observations in terms of a spontaneous decay of this particle.

Assumption of a Spontaneous Decay of the *k*-Particle

In examining the possibility that the transmutation *A* corresponds to a spontaneous decay of the particle *k*, we require to know the relative directions of motion of the three ejected particles. For this purpose it is necessary to determine the shrinkage of the emulsion; the ratio, *S*, of the thickness of the emulsion during exposure to that after it had been developed, fixed and dried. We have measured this quantity by examining the tracks of α-particles, produced in the emulsion by uncontrolled radioactive contamination. Among such 'stars', it is possible to identify some, due to an original atom of radiothorium, from which an α-particle of thorium C′ was emitted. The shrinkage has been measured by determining the lengths of the projection of the corresponding tracks on the surface of the emulsion, and their apparent angles of 'dip'. The value of the 'shrinkage' thus found is $S = 2\cdot7 \pm 0\cdot1$. Knowing the value of *S*, the original orientation of a track in the emulsion, before processing, can be determined, in favourable cases, with a precision of the order of 1°, by observing the apparent angle of 'dip' of the particle, and the direction of its projection on the plane defined by the surface of the emulsion. Using these methods, the original directions of motion of the three particles *a*, *b* and *t* were found to be coplanar. The departure of the direction of motion of any one particle from the plane defined by the other two is less than 4°. The error in this determination is largely due to the fact that track *t* is of short range, and the particle producing it was of low velocity, and frequently scattered.

The values of the angles between the directions of motion of the particles in the common plane are shown in Fig. 12. The observed coplanarity makes it legitimate to assume that the three particles arise as a result of the spontaneous decay of the *k*-particle at the end of its range in the emulsion, and that they are the only product of its disintegration; that no neutral particles, which would escape observation, are emitted. It follows that the vector sum of the momenta of the three particles must be assumed to be equal to zero.

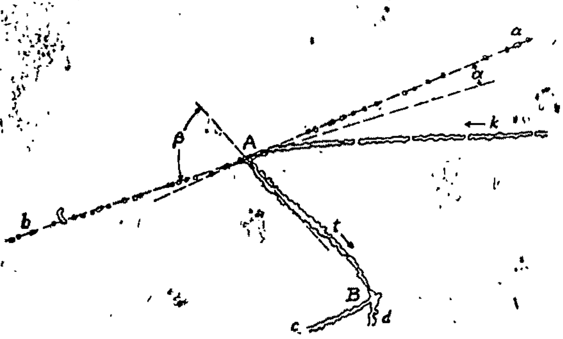

Fig. 12. Facsimile drawing of the event shown in Fig. 8, made with the projection microscope. The actual angles α and β, measured in the common plane of the three tracks, *a*, *b* and *t*, are: $\angle\alpha = 9\cdot8°$; $\angle\beta = 76\cdot6°$

If we are correct in attributing the track *t* to a π^--particle, it follows from the observed range, 45 μ, that the kinetic energy of ejection was 1·04 MeV. The corresponding value of the momentum of the particle is 17·5 MeV./*c*. From the observed directions of motion, the momenta of the particles giving tracks *a* and *b* are then found to be 98 ± 5 and 104 ± 5 MeV./*c*, respectively. These values are to be compared with those corresponding to electrons or mesons listed in Table 2, which have been deduced from the observed grain-density in the tracks. We have seen that the values given in Table 2 for the momenta of the two particles, if they are assumed to be electrons, are many times too large. It follows that there is a wide departure from a momentum balance if the tracks *a* and *b* are assumed to be due to either electrons or protons. Further, the values of the momenta, as deduced from observations on the scattering of the particles, are inconsistent with those obtained from grain-counts, if the particles are assumed to have been either electrons or protons (see Table 2).

The agreement between the sets of values for mesons, however, is most remarkable, and gives strong support for the assumption of a spontaneous decay of the *k*-particle. Only a very rare combination of unrelated features, including the coplanarity of the tracks and the directions of motion of the particles in the common plane, the range of the particle *t*, and the specific ionization of the particles producing tracks *a* and *b*, could produce such an agreement between the estimated values of the momenta, if the result is fortuitous.

The values of the momenta of the particles producing tracks *a* and *b*, as determined by the three different methods, are consistent, within the errors of measurements, with the assumption of a spontaneous decay of the *k*-particle whether the product particles are assumed to be μ-mesons or π-mesons. We can apply a further test by calculating the values of the rest-mass of the particle *k* which corresponds to the two different assumptions, and the results are tabulated in Table 3.

TABLE 3. Estimates of the mass of particle *k* based on total release of mass and energy, for two assumed modes of decay

(i) $k \rightarrow \pi^- + \pi + \pi$

	Track '*a*'	Track '*b*'	Track '*t*'
Particle	π	π	π^-
Rest-mass (m_e)	286	286	286
Energy in m_e	61	64	2

Total = m_k = 985 m_e

(ii) $k \rightarrow \pi^- + \mu + \mu$

	Track '*a*'	Track '*b*'	Track '*t*'
Particle	μ	μ	π^-
Rest-mass (m_e)	212	212	286
Energy in m_e	76	81	2

Total = m_k = 869 m_e

In calculating the energy of the particles producing tracks *a* and *b*, it is assumed that the particle producing track *t* is a π^--particle, of momentum 17·5 MeV./*c*; knowing the relative directions of motion of the three ejected particles, the momenta of the other two particles are determined, and hence the energies corresponding to any assumed mass.

It will be seen from Table 3 that the assumption of two µ-mesons corresponds to a rest mass of the k-particle of 869 m_e; and for two π-mesons, 985 m_e. The assumption of different particles, one π- and one µ-meson, gives an intermediate value of approximately 925 m_e. In view of the error in the direct determination of m_k, the results are not decisive.

If the transmutation is to be interpreted in terms of particles of which the existence is already established, we are left with four possibilities for the nature of the particles producing tracks *a* and *b*. These are indicated schematically in Table 4.

TABLE 4. Comparison of the observed and calculated values of the grain-density in track *b*, for various assumptions regarding the nature of the particles producing the tracks *a* and *b*

	Length of track in microns	Number of grains	Grain-density	Assumed particles 1	2	3	4
Track *a*	2100	1025	49 ± 1·5	π	μ	π	μ
Track *b*	116	59	51 ± 6	π	μ	μ	π
Calculated grain-density in *b*				45	45	34	64

Values of the grain-density are given in grains per 100 µ.

For the following reasons, case 3, Table 4, is the most improbable. If track *a* is that of a π-meson, we can calculate the momentum and the grain-density to be expected in track *b*. We thus obtain the value of 34 grains per micron instead of 51·0 ± 6·0 as observed. For case 4, on the other hand, if *a* is a µ-meson, the calculated grain-density for track *b* is 64, a value which differs from that observed by an amount only twice that corresponding to the standard deviations. The observed grain-densities agree best with the assumption that the two particles are of the same type.

Observations on the scattering of the particle producing track *a* are in better accord with the assumption that it is a π-meson rather than a µ-meson (see Table 2); but the results are again indecisive. We may sum up this evidence, and that provided by the mass determinations by grain-counting, by saying that there is some support for the view that the three product-particles are π-mesons; but that the alternative possibilities of one π- and two µ-, or two π- and one µ-meson cannot be excluded.

Chance Juxtaposition of Unrelated Events

In the light of the analysis made in the preceding sections, we can now return to the original assumption that the event is not to be regarded as a fortuitous juxtaposition of tracks. The accuracy of the determination of the mass of the particle *k* does not allow us to exclude the possibility that it has a mass as great as that of a proton, although the observations by grain-counts render it very improbable. Suppose then that a proton, unrelated to the particles producing the other tracks, came to the end of its range at *A*. Even with this assumption, the event is still difficult to explain in conventional terms. Many examples of π^--particles ejected from stars have been observed in this Laboratory[6], but in the present instance the existence of a nuclear interaction in which two protons of great energy are emitted, unaccompanied by slow protons and α-particles, would remain to be explained. A similar difficulty is met if we assume that a particle producing one of the tracks, *a* or *b*, approached *A* and produced the transmutation.

If, alternatively, the tracks *c* and *d*, diverging from star *B*, represent an unrelated disintegration—produced, for example, by a γ-ray—we could then assume track *t* to be that of a proton. We are then left with the difficulties associated with the features peculiar to star *A*, which must now be assumed to have been produced by a slow, charged particle; difficulties which have already been discussed in a previous paragraph. These considerations give further support to the original assumption, that all the tracks shown in the mosaic represent a succession of associated processes.

Relation of the Present Results to Other Observations

If a particle with the elementary electronic charge suffers a spontaneous decay, the law of the conservation of charge demands that the number of emitted particles of charge *e* shall be odd. From this point of view, the sign of the charge of the original particle can have been either positive or negative. If the particles producing tracks *a* and *b* form a pair of opposite sign, then the original k-particle was negative. The only other alternative is that they were both positively charged, in which case the k-particle was also positive. It is therefore possible that our observations correspond to a mode of decay of positive particles of mass approximately 900 m_e, and that the observation by Leprince-Ringuet[2] demonstrates the fate of the corresponding negative particles—nuclear capture with the production of a 'star' and the ejection of a π^--particle.

Rochester and Butler[2] have published an expansion-chamber photograph which appears to be due to the spontaneous decay of a neutral particle of mass approximately 900 m_e into a pair of oppositely charged particles of rest-mass approximately 300 m_e. We have therefore considered the possibility that the decay process suggested by the present results can be regarded as taking place in two stages: the emission of a π^--particle of low energy, followed by the spontaneous decay of the resulting neutral particle. On this view, however, it would be necessary to assume that the neutral particle has a life-time of the order of 10^{-14} sec. Otherwise, in recoiling from the π-particle, it would move away from the original point of decay, and the two charged particles into which it became transformed would originate from a point separated from the beginning of the track of the π^--particle. It follows that we cannot identify such a postulated unstable neutral particle with that for which evidence is provided in the experiments of Rochester and Butler.

Finally, we have considered the possible relations of the present results to the particles of mass approximately 800 m_e referred to as τ-mesons, evidence for which has been recently reported by Bradt and Peters[2]. It is a remarkable feature of their experiments that their τ-mesons give rise to no recorded secondary particles at the end of their range. It appears to be possible that these particles also decay with the emission of three fast mesons, but that the transmutation usually takes place with a more equal partition of kinetic energy than in the case we have observed. It would then follow that in the Ilford *C2* emulsion the disintegration products would commonly escape observation. If this view is correct, we must regard the event we have observed as representing a rare example of a common mode of decay of these mesons; an example which, by chance, has allowed a detailed analysis to be carried out. If so, the τ-meson of Bradt and Peters, when recorded by electron-sensitive emulsions, should show the tracks of three particles, of low specific ionization, and of which the directions of motion are co-planar.

We have pleasure in thanking Prof. von Muralt and members of the staff of the Jungfraujoch Forschungsstation for hospitality and assistance in obtaining the exposures; Dr. E. R. Davies and Dr. W. E. Berriman, of Messrs. Kodak, Ltd., for special photographic plates; Miss C. Dilworth and Dr. G. P. S. Occhialini for advice on development; Mr. W. O. Lock and Mr. J. H. Davies for assistance in making observations on the scattering of particles in the emulsion; and to the team of microscope observers of this Laboratory. We are indebted to Prof. N. F. Mott and other colleagues for a number of discussions on the processes associated with the capture of negative mesons by nuclei.

Note added in proof. Since completing this article, we have been informed by Dr. Peters that, in Ilford *C*2 emulsions exposed at 90,000 feet, he and Dr. Bradt have observed three events with the following characteristics. A particle, which they judge to be similar in mass to their τ-mesons, appears to come to rest and to lead to the emission of a particle of smaller mass, which, at the end of its range, produces a nuclear disintegration. The ranges of the secondary particles, in the three cases, are 20, 25 and 45 μ, respectively. The authors were not aware of our results when they suggested to us that their observations may correspond to the spontaneous decay of heavy mesons. According to their description, these events are precisely similar to those we should expect to observe in *C*2 emulsions as a result of the spontaneous decay of heavy particles of the type we have postulated; for any particles of low specific ionization will not be recorded by the Ilford plates. The observations of Peters and Bradt appear, therefore, to give further support for the assumption that the present observations are not due to a chance juxtaposition of tracks; and they suggest that it will be possible, in the near future, to find similar examples suitable for making a detailed analysis.

DEVELOPMENT OF LEATHER CHEMISTRY

THE first applications of scientific knowledge to the problems of leather manufacture may be said to have been made about 1890, and the initiation in the following year at the Yorkshire College (now University of Leeds) of a course of lectures devoted to the subject was an indication that a new field of technology had gained recognition. Five years later, through the foresight and generosity of local tanners and the Worshipful Company of Skinners, a special department was built to house the new subject, and H. R. Procter was appointed to fill the newly created chair in 1898.

The industry, which was being encouraged to examine its methods along scientific lines, was one dating from primitive times, and little advance had been made in methods of manufacture or in the principles underlying them since their inception. Moreover, and perhaps because of this, the industry as a whole was a conservative one, and early workers in the field had to contend with a rooted distrust of new ideas which took a long time to break down. It was without doubt fortunate for the future development of the subject that the man chosen to hold a key position at the outset was Procter, who deservedly earned the title of 'father of leather chemistry'. Working in a more leisurely age than the present, he did not publish his well-known theory of protein swelling until 1916; but during the intervening years he was laying the foundations firmly by his influence on the succession of students who passed through his hands, as well as by his own published work. Largely by reason of his efforts, the industry was of a sufficiently scientific turn of mind by 1920 to support the foundation of the British Leather Manufacturers Research Association, which is one of the oldest associations of its kind in Great Britain. The growth of knowledge in this field, and the amount of work which has been done, may be appreciated by a perusal of three publications issued to commemorate the twenty-fifth anniversary of this Association*, which is, in effect, a summary of almost all important investigations relating to leather carried out during the period throughout the world.

Since the materials used in leather manufacture are of many different types, both organic and inorganic, and as the processes employed involve to some extent the application of almost all branches of chemical knowledge, there can be few other industries in which the research worker must be familiar with so many different aspects of chemistry. Many problems have been elucidated by virtue of investigations in other subjects, probably the most fruitful contributions coming from biochemists, especially those working on proteins, as a result of which the composition and structure of the tanner's most important raw material, collagen, is more or less settled. From the realm of organic chemistry have come numerous studies on the constitution of the tannins which, from Fischer's early synthesis of penta-*m*-digalloyl-β-glucose and from Freudenberg's work on the condensed tannins to the work of present day, have materially contributed to the understanding of vegetable tanning. Information on these matters is, however, by no means complete, and recent research, especially on the important tannin constituent of mimosa bark, has directed the attention of leather chemists in particular to the importance of this line of investigation.

In this branch of their subject, as in many others, leather chemists have in many cases made notable contributions not only to the understanding of their own problems but also to chemical knowledge in general. It may not be widely known that Procter's work on the swelling of gelatine was promoted by the observation of swelling phenomena in hides during operations prior to tanning; and the discovery that chromium salts were valuable tanning agents led to a large amount of research on the properties of their solutions, with results of wide interest.

---

* Progress in Leather Science, 1920–1945. Vols. 1, 2, 3. Pp. xvi+705. (London: British Leather Manufacturers Research Association, 1946–48.)

Much of the fundamental work on tannery processes has been concerned with the mechanism of tannin–collagen combination, although tanning itself is only one of a large number of operations involved in the manufacture of leather. Several general lines of attack on the problem have yielded valuable information, no matter which type of tanning agent, organic or mineral, has been under examination. The introduction in 1934 of the shrinkage temperature as a measure of the thermal stability of collagen has been used not only as an indication of the increase in cross-bonding between adjacent polypeptide chains which occurs in some types of tanning but also as a means of clarifying protein structure; and some of the latest published work of Jordan Lloyd, who was director of the British Leather Manufacturers Research Association from 1927 until her death in 1946, was concerned with the shrinkage temperature of collagen in organic solvents. Modifications of the reactive groups in collagen by de-amination to remove the lysine amino group, removal of the guanidine group of arginine by Sakaguchi's method, combination with formaldehyde, and methylation, have all been carried out; and the effect has been considered on such properties as combination with acids, bases and tanning agents. Similarly, the influence of modification by tanning on the acid- and base-combining capacity of collagen, and the effect of combination with one type of tanning agent on its behaviour to another contrasted type, have been widely studied. The role of hydrogen ion concentration in manufacture is now well understood, and has been interpreted in conformity with the zwitterion theory of protein structure.

The vegetable tanning process presents a number of questions which have not been answered; and several theories on the mode of combination of tannin and collagen have been proposed, ranging from an adsorption mechanism to salt formation involving the amino groups of the protein molecule. The concept of hydrogen bonds has been invoked to explain not only tannin–collagen combination, but also the relatively large amount of tannin fixed in leather; and it is thought that tannin is bound to tannin by means of hydrogen bonds, and that only about half the tannin shown by analysis to be 'fixed' is actually attached to the protein. In fact, all types of chemical bonds play a part in the process to an extent depending on the constitution of the tannins present, external conditions in the tan liquors, such as *p*H and other factors; and it would be impossible to distinguish the extent of each in any given sample of leather. More important from the tanner's point of view is the fact that much knowledge has been gained about the functions of the non-tannin constituents of the liquors with which he makes sole leather, especially the large number of acids and salts present, which have a profound effect on the quality of the leather produced. In this case, the problem has largely been one of analytical procedure and has been partly solved by the use of ion-exchange resins, combined with the examination of the titration curves of the liquors; but recently the method has been subjected to some criticism.

The chrome-tanning process has proved no less intractable than that using vegetable tannins. It was not until some insight had been gained into the chemistry of chromium salts that any successful attempt could be made to enunciate a theory which would explain the phenomena accompanying chrome-leather manufacture, although the conditions necessary for successful tannage were known long before the reasons for them, especially the importance of the acidity of the bath. The application of Werner's co-ordination theory has proved of enormous value in explaining the course of the reaction, and most theories assume the co-ordination of the chromium complex with some part of the collagen molecule. The increase in *p*H necessary to obtain combination between collagen and the chromium compound affects both the complex itself and the protein, and co-ordination could occur between an ionized carboxyl group and the complex. It seems very likely that combination takes place between adjacent polypeptide chains through the complexes, and this is one explanation of the high degree of stability of chrome-tanned leather towards boiling water. Attempts to explain chrome-tannage on the basis of salt formation have not been so successful, except in cases where anionic complexes are present in the tanning bath.

What might be referred to as less important methods of tanning have not received as much attention, except in the case of formaldehyde, which is linked to the wider problem of the protein–formaldehyde reaction. Quinone tannage, although of no commercial importance at present, has nevertheless been investigated for the light it throws on the vegetable-tanning process.

Many operations other than tanning have been investigated by leather chemists; but space allows mention of only a few. The liming process for the removal of hair, especially the function of unhairing agents in accelerating the reaction, has been explained in the light of a great deal of work carried out on wool, while the effect of the same operation on collagen has been shown to involve mainly the amide groups and possibly the arginine. The most important modification which collagen undergoes in liming is in the alteration of the fibre structure due to plumping, and in the separation of the fibre bundles into fibrils.

Some of the most valuable work carried out, particularly by the British Leather Manufacturers Research Association, has been in the development of microscopic examination as a guide to the quality of leather, and the large number of photographs in the publications referred to bears testimony to the extent to which this method has been adopted. In the field of physical testing, methods have been introduced for the determination of permeability of leather to water and water vapour, resistance to abrasion and allied phenomena, all of which, with certain reservations, give a more immediate and practical indication of quality in use than the older method of chemical analysis. A great deal of less spectacular work has enabled tanners to overcome faults derogatory to the value of their products, such as stains resulting from bacterial action in the curing of the raw hides, various exudations known under the term 'spues', liability of some leathers to rot in acid atmospheres and many other similar defects. These operational problems have been the cause of a large amount of work in Great Britain and the United States for a number of years; but it is true to say that the resistance of vegetable-tanned leathers to acid deterioration especially has been markedly increased.

It has been possible in a short space to indicate briefly no more than a few of the advances made during the last quarter of a century. The chief contributions to the problems involved have been made by chemists in Great Britain, on the continent of Europe, and in the United States, where an Association of Leather Chemists was formed in the early years of this century. Many papers have been published from laboratories of industrial organisations and private firms, which alone shows how far the industry has moved since Procter's early days. In the last decade or so, schools of tanning with attendant research organisations have grown up in South Africa, Australia and New Zealand. While the field has been expanding rapidly, no leather chemist can claim that more than a fraction of the problems which face him has been settled, and it becomes more apparent yearly that most of the operations with which he deals are far more complicated than had been realized. In regard to fundamental problems, the past twenty-five years have seen a notable clearing of the ground. In the realm of manufacture, it is probable that in the future much more attention will be paid to the use of synthetic agents for many tannery processes as replacements for time-honoured natural materials, which for one reason or another are becoming less easily available each year. P. Danby

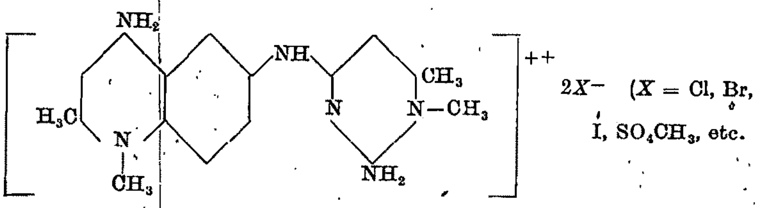
'ANTRYCIDE': A NEW TRYPANOCIDAL DRUG

By (the late) Dr. F. H. S. CURD and Dr. D. G. DAVEY

Imperial Chemical Industries, Ltd., Research Laboratories, Manchester, 9

THE discovery of a new drug, 'Antrycide'*, showing great promise in comprehensive field trials as a trypanocide, has already been referred to in an announcement from the Colonial Office. This new drug resulted from a systematic study of the chemotherapy of trypanosomiasis in these Laboratories, and although a full account of our researches must await later publication, a few preliminary observations may be of interest.

After considerable chemical exploration, 4-amino-6-(2′-amino-6′-methylpyrimidyl-4′-amino) quinaldine-1 : 1′-dimetho salts were found to possess outstanding trypanocidal properties against laboratory infections.



These salts, which have the accompanying formula, will be referred to for convenience as 'Antrycide' salts.

We give in Table 1 a brief summary of the experimental findings obtained with one of these salts in the treatment of various trypanosome infections in mice; in all experiments the drug was administered subcutaneously.

Against a *Trypanosoma congolense* infection, a single dose of 1 mgm. of 'Antrycide' chloride per kilo body-weight was curative. Half this dose effected a proportion of cures. Similarly, activity was shown by this compound against many other experimental trypanosome infections, for example, against those due to *T. rhodesiense*, *T. brucei*, *T. evansi* (India), *T. evansi* (Sudan), *T. equiperdum* and *T. equinum*. Susceptibility to the drug of the different trypanosome species was not uniform throughout the series, but by adjustment of the dose, cures could be obtained in every case. We did not encounter marked toxic effects even with doses many times those necessary for cure.

It should be noted that the figures in Table 1 relate to particular strains of the trypanosome species indicated. Some variation was experienced with certain other strains; for example, one strain of *T. congolense*, isolated in Kenya, showed marked resistance compared with the Busimbi strain, and a dose of about 2·5 mgm./kgm. was required to produce consistent cures in mice.

'Antrycide' salts also possess marked prophylactic action against experimental trypanosome infections. Mice, rats and rabbits were first treated with the drug, and then after a varying period of time were 'challenged' with trypanosomes. It was found that, with suitable doses, the animals could be protected against infection for some weeks. The results of some typical experiments with *T. congolense* (Busimbi strain) in mice are recorded in Table 2. If no trypanosomes were to be found in the blood 28 days after challenging, then the animals were regarded as completely protected (*P* in Table 2). Incomplete protection (*I*) was judged by delayed death as compared with untreated control animals or by the appearance of trypanosomes in the blood of the test animal before completion of the experiment.

Table 1. Trypanocidal action of 'Antrycide' chloride against various *Trypanosoma* species

Dose (mgm./kgm.)	*T. rhodesiense* (Tinde)	*T. brucei* (Liverpool)	*T. congolense* (Busimbi)	*T. evansi* (India)	*T. evansi* (Sudan)	*T. equiperdum*	*T. equinum*
25	*C*						
12·5	*C*						
5	*C*	*C* and *R*					
2·5		*R*		*C*	*C* and *R*		*C*
1·25			*C*	*C*	*C* and *R*	*C*	*C*
1·0			*C*				
0·5			*C* and *R*	*C* and *R*	*R*	*C*	*C* and *R*
0·25			*R*			*C* and *R*	
0·125			*R* and *DD*				

C = Cure: blood freed from trypanosomes for 28 days. *R* = Relapse: blood freed from trypanosomes temporarily, appearing again within 28 days. *DD* = Delayed death: blood not freed from trypanosomes

---

* Trade mark of Imperial Chemical (Pharmaceuticals), Ltd.

Table 2. Prophylactic experiments in mice infected with *T. congolense* (Busimbi) using 'Antrycide' chloride

Dose (mgm./kgm.)	Interval between dosing and challenging (days)	Result
25	14	10/10 *P*
12·5	14	8/8 *P*
5	14	4/11 *P*. 7/11 *I*
25	28	8/8 *P*
12·5	28	8/8 *P*
5	28	8/8 *I*
12·5	42	2/6 *P*. 4/6 *I*
5	42	8/8 *I*

Our laboratory results appeared to us to justify field trials, and in association with the Tsetse Fly and Trypanosomiasis Committee of the Colonial Office, and with the Sudan Government, veterinary trials were commenced in Africa. Although these trials are still incomplete, the evidence already available shows that 'Antrycide' salts may be administered subcutaneously with ease and safety and, in single doses, have cured infections of *T. congolense*, *T. vivax* and *T. brucei* in cattle, *T. brucei* in horses, donkeys and dogs and *T. evansi* in camels. 'Antrycide' salts have also been shown by us to give considerable protection to cattle against subsequent infection with *T. congolense* and *T. vivax*. Experiments are still in progress to determine the duration and the character of this prophylactic action, and to ascertain whether the drugs can be used successfully for the protection of cattle maintained in or transported through tsetse areas of tropical Africa. The good correlation obtained so far between laboratory and field results encourages us to expect prophylactic effects of importance.

OBITUARIES

Dr. F. H. S. Curd

The tragic death on December 2 of Francis Henry Swinden Curd, following injuries received a few days earlier in a railway accident, robs chemotherapeutic research of one of its foremost workers, and at an age when his qualities were approaching full fruition.

Born in 1909, he received his early education at Bancrofts School, Woodford. Passing to East London College (Queen Mary College), he graduated in the honours school of chemistry in 1930. There began his association with Dr. (now Prof.) Alexander Robertson, with whom he remained when the latter was appointed to the London School of Hygiene and Tropical Medicine. Until 1933 he collaborated in researches on the synthesis of compounds related to the lichen acids, for which he gained his Ph.D. Although this work did not bear directly on the chemotherapy of tropical diseases, there is little doubt that his interest in this subject was first aroused during the years spent at the London School.

In 1933 he entered the research laboratories of Imperial Chemical Industries, Ltd., at Blackley, Manchester, and like many earlier workers in the field of chemotherapy, served his apprenticeship on an investigation of the chemistry of dyestuffs. Some part of his time, however, was given to a continuation, with Mr. S. Ellingworth, of the studies on the styrylquinoline series of trypanocidal drugs which the latter worker had earlier begun with Prof. J. B. Cohen. In 1936, he was seconded to the newly formed Medicinal Chemicals Section, and for the next three years devoted his full attention to trypanosomiasis.

The shadow of approaching war caused this work to be interrupted, and Curd began the task of devising routes to the German synthetic antimalarial drugs, 'Atebrin' ('Mepacrine') and 'Plasmochin' ('Pamaquin'). Despite the lack of published information on preparative methods, these problems were solved during 1939, and his work laid the foundation for a large-scale manufacture, particularly of 'Mepacrine', at that phase of the War when the drug was most urgently needed.

Experience with this substance indicated its shortcomings and, as in other parts of the world, stimulated the search for more effective agents. Curd was again entrusted with this task, and he began by making an exhaustive study of the existing extensive literature on the chemotherapy of malaria (*Ann. Trop. Med. and Parasit.*, 1943) which stands as a model of what such a survey should be. His attention was early directed to the pyrimidine nucleus as the basis for new synthesis, and with his colleagues he rapidly developed entirely new chemotherapeutic types which culminated in the preparation, in 1944, of the diguanide 'Paludrine'. For his part in this work he was awarded in 1947, jointly with D. G. Davey and F. L. Rose, the Gold Medal for Chemotherapy of the Worshipful Society of Apothecaries.

More recently, Curd's attention had turned again to the problem of trypanosomiasis; and although he died before seeing the completion of his new work, there is little doubt that the outcome of his later researches, when fully revealed in the results of field-trials now in progress in Africa, will mark him as an outstanding figure in chemotherapeutic research, and will emphasize the national significance of his loss. [A preliminary account, with Dr. D. G. Davey, appears on p. 89.—Editors.]

Curd's personal attributes were known to a wide circle of friends in industry, universities and research institutions. A natural gentleman, at all times charming and modest, he was characterized by meticulous care in all he did, and by an enthusiasm which inspired everyone with whom he came in contact. He leaves a widow and three young daughters.

F. L. Rose

By the death of F. H. S. Curd the science of chemotherapy has lost an outstanding contributor. In the years he devoted to the chemotherapy of the parasitic diseases, Curd and his co-workers achieved results the scientific and practical importance of which have not been surpassed in this field. That the investigations in which he was engaged proceeded with smoothness and certainty was largely due to Curd's personal qualities. His sound common sense, well-developed critical faculties, and an unassuming wealth of knowledge allied to remarkable technical ability ensured the hearty co-operation of his associates, chemical, biological and medical, and promoted the directional stability of the investigations in which he played so prominent a part. His place will indeed be difficult to fill.

A. R. D. Adams

We regret to announce the following deaths:

Mr. J. H. Coste, chemist-in-chief of the London County Council during 1913–36, on January 3, aged seventy-seven.

Mr. T. Petch, formerly Government mycologist, Ceylon, later director of the Ceylon Tea Research Institute, on December 24, aged seventy-eight.

NEWS and VIEWS

Physical Chemistry at Manchester: Prof. M. G. Evans, F.R.S.

PROF. M. G. EVANS goes from Leeds to Manchester this month to succeed his former teacher and collaborator, Prof. M. Polanyi, in the chair of physical chemistry. In 1939 he was appointed to the chair of physical chemistry in the University of Leeds, made vacant by the death of Prof. H. M. Dawson, and in 1945, when Prof. R. W. Whytlaw-Gray retired and the Departments of Inorganic and Physical Chemistry were fused, he became the senior professor in the combined department (see *Nature*, **156**, 386; 1945). Immediately on appointment to Leeds, Prof. Evans found himself confronted with all the problems of adapting the work of an important teaching and research school to war-time conditions; but not content merely to keep an efficient department going, he laid the foundations for the great developments which have since taken place. His infectious enthusiasm for his subject has been as effective in teaching as in research, and the inspiring originality which he brought to bear on the organisation and conduct of the teaching of inorganic and physical chemistry in Leeds will long continue to exert its influence there.

Prof. Evans' researches in many fields of physical chemistry were recognized by his election to the Royal Society in 1946. While in Leeds he has contributed largely to the knowledge of the reactions of free radicals in aqueous solution, with special reference to polymerization reactions. His work has been characterized by a particularly happy combination of experiment and theory, and his theoretical work on the energetics and kinetics of free radical and polymerization reactions has been especially noteworthy. He has also made important contributions to the study of oxidation-reduction reactions and of diffusion problems. During the War Prof. Evans played a leading part in planning and carrying out investigations on chemical defence problems. His activities ranged over a wide field, and whether in committee work, in theoretical discussions or in practical breathing tests in toxic clouds, he did not spare himself. During the past nine years, Prof. Evans has given unstinting service to the University of Leeds as a whole. His transference to Manchester will be felt not only in the Council, Senate and lesser bodies at Leeds, but also by many of his colleagues who have been accustomed to rely on his wisdom, good judgment and human sympathy for help in a variety of matters often very remote from chemistry.

Mining at Birmingham: Prof. S. G. Ward

PROF. STACEY G. WARD has accepted the invitation of the Council of the University of Birmingham to the chair of mining and to become director of the Mining Department; he is relinquishing the chair of chemical engineering which he has held since 1946. Prof. Ward obtained his fundamental scientific and engineering education in the Imperial College of Science and Technology, London, and carried out research in pure chemistry before transferring to research on coal. He has been intimately connected with the mining industry since 1930, when he joined the Powell Duffryn Company. For three years prior to appointment in 1937 to the staff of the Mining Department at the University of Birmingham, he was field research and liaison officer to the British Iron and Steel Federation. He was acting professor of mining from 1943 until the appointment of Prof. T. David Jones in 1947, and, at the request of the Faculty of Science, became acting head of the Department after Prof. Jones' death in that year.

It is intended to expand the Department of Mining at Birmingham, which includes coal mining, coal preparation and treatment, metalliferous mining and mineral dressing, not only on the teaching side but also, and particularly, in connexion with research. Special attention will be paid to teaching fundamental subjects and principles involved in mining, and it is hoped to reserve time in the course for liberal studies. The research work will be expanded, in the first place, on that now in progress on fundamental problems of ventilation, drilling, mine lighting, mineral dressing, coal constitution, spontaneous combustion and coal cleaning (on which Prof. Ward has had a team working for some time). Special post-graduate courses for those who have had industrial experience will be introduced. The reorganised Department will eventually be accommodated in new buildings and laboratories which have already been planned but for which building permits cannot yet be obtained.

Physiology at Liverpool: Prof. R. A. Gregory

DR. R. A. GREGORY, who has recently been appointed to the Holt chair of physiology in the University of Liverpool, is an honours graduate in physiology of the University of London (University College). While at University College he held the Bayliss–Starling Memorial and Sharpey Scholarships, and received College and University awards. His work up to that time had been on biochemical problems of carbohydrate metabolism, the circulation, with particular reference to the metabolism of the heart, and the resistance of the body to hot environments. In 1939 he was awarded a Rockefeller Foundation Fellowship, spending most of his time in A. C. Ivy's laboratory in Chicago, where he became interested in problems of the gastro-intestinal tract. On his return to Great Britain, the surgical technique he had acquired enabled him to make valuable contributions to one of the war-time research projects fostered by the Ministry of Supply. After the War, during which he held the post of lecturer at University College, he was appointed senior lecturer in the University of Liverpool and resumed his work on the fundamental physiology of digestion. In addition to numerous papers in physiological journals, he has contributed chapters to Wright's "Veterinary Anæsthesia" and Winton and Bayliss' "Human Physiology". Prof. Gregory succeeds Prof. W. H. Newton, who has been appointed to the chair of physiology at Edinburgh.

Wellcome Chemical Research Laboratories: Dr. S. Smith

DR. SYDNEY SMITH, who recently retired from his appointment as director of the Wellcome Chemical Research Laboratories, will retain a connexion with the Wellcome Foundation, Ltd., as consultant. Dr. Smith joined the staff of the Wellcome Chemical Works at Dartford in 1914 and served for many years as head of the experimental laboratories. He initiated and developed many important technical processes, and in pure research became well known for his discovery of digoxin. He became works manager in 1936, and in the following year was appointed a director of the Wellcome Foundation, Ltd. In 1941 he left the works in order to establish the new Wellcome Chemical Research Laboratories at Beckenham. Here, after setting up temporary laboratories, he was responsible for the planning and development of the extensive permanent laboratories opened in 1946.

A Giant Meteorite

IN the issue of *L'Astronomie* for October 1948 there is an account of an enormous meteorite which, on February 12, 1947, fell in the Sihot-Alin chain of mountains, in the vicinity of the Amoor River, Eastern Siberia. M. Krynov, secretary of the Commission of Meteorites of the Academy of Sciences of the U.S.S.R., who took part in the expedition which investigated the nature of the phenomenon, states that this meteorite is probably one of the largest that has ever struck the earth, and M. Fessenkov, who presides at the work conducted on meteorites, believes that the object was a minor planet. The fall was observed by the inhabitants of towns and villages over a radius of 200 kilometres around the place of impact, and those who were questioned agree that the body was moving from north to south, that its time of flight was between four and five seconds, and that it was more brilliant than the sun which was then shining on a beautiful morning in a clear sky. The noise of the fall and of a series of explosions which accompanied the flight of the object could be heard at distances of 200 km. Preliminary estimates of its mass give this as about a thousand tons.

It has been estimated that the speed of the meteorite was about 20 kilometres a second and that its surface temperature, acquired by friction with the atmosphere, was of the order of 5,000° C. It broke up into thousands of fragments of various sizes, and these lost their speed by friction with the atmosphere, falling on the earth merely by its gravitational attraction. Pieces were found over an area represented by a circle of 12 km. radius. In an oval sector of 0·75 sq. km. the members of the expedition found more than a hundred funnels in the rocks, caused by the fall of the debris, the diameters of these funnels varying from 0·5 to 28 m., and some of them attained a depth of 6 m. All around were found trees overthrown or damaged, and a number of large cedars were found split in two. On examining very carefully the neighbourhood of the fall, the expedition of 1947 discovered 257 fragments of the meteorite, varying in weight between 0·16 gm. and 1·8 tons, and about 5 tons of cosmic iron were collected, while the next expedition in 1948 collected about 4 tons more. Aerial photographs of the region were taken during 1948, and about 48 sq. km. have been declared a closed district and placed at the disposal of the Academy of Sciences of the U.S.S.R. for five years.

Jurassic Holostei

THE questions of the classification of the fishes and of the interrelationships of the different groups are occupying the attention of modern zoologists. In such a study, which involves fossil forms, a consideration of the bones of the skull and their homologies must play an important part. The dermal bones, among other skeletal structures, are often quite well preserved and so have received much attention. On the other hand, the neurocrania, being partly obscured by the dermal bones and only capable of study in particularly well-preserved specimens, are nothing like so well known although quite important. Hence the interest of a study of the neurocrania of some Jurassic Holostei recently made by Dr. Dorothy H. Rayner (*Phil. Trans. Roy. Soc.*, B, **601**; 1948). A special technique involving the grinding of the specimen and the taking of a series of transfers 0·1 mm. apart was elaborated from a previous method suggested by E. C. Case in 1937. An appendix describes the technique fairly fully, and it will probably be of use in other lines of work involving the sectioning and reconstruction of fossil material. In spite of considerable variation in the neurocranial ossifications, which differ among closely related forms and apparently in the same species with difference of age, there is, save in the supraoccipital and post-otic regions, sufficient similarity to allow of broad homologies being drawn. This and other evidence adduced suggests that the Jurassic Holostei may be regarded as a natural group. Two particular points may be noted. There is sufficient similarity between the neurocrania of the Jurassic *Lepidotus* and the living *Lepidosteus* to suggest relationship between them, and in *Caturus* and *Dapedius* there is a lateral cranial canal without external opening to which, at present, no function can be assigned.

Mental Health and World Citizenship

THE World Federation for Mental Health has published as a booklet a statement produced by the International Preparatory Commission for the International Congress of Mental Health which met in London in August 1948. Although the statement will appear in the published Proceedings of the Congress, the expressed wish that it should be given a wide circulation has resulted in its production in the present form. The International Preparatory Commission sat for a fortnight prior to the Congress and was made up of twenty-four persons from ten different countries representing the points of view of sociology, psychology, psychiatry, social work, anthropology, political science, philosophy and theology. As the raw material for its deliberations, reports were available from three hundred preparatory commissions composed of about five thousand workers in the different fields who had been working during the preceding year in twenty-seven countries. The booklet is obtainable from H. K. Lewis and Co., Ltd., 136 Gower Street, London, W.C.1.

Family Health Service in South Africa

THE current issue of *Biology and Human Affairs* (14, No. 2; Autumn 1948) contains an article on the Family Health Service in South Africa, where twenty health centres have been established in various parts of the country by the Ministry of Health. A description is given of the Polela Health Centre which was set up in 1940 in a rural native reserve in south-western Natal. The family health service was first applied to a small area within the reserve and was gradually extended until, within four years, almost six thousand people were included in the scheme. This has led to a marked improvement in the health indices in that part of Polela where the family health service is in operation, and other health services have now been planned for the reserve, so extending the facilities to the entire population of the area. The article contains a detailed account of the way in which the service has been organised.

Humanitas

THE autumn number of *Humanitas*, just issued, completes the second year of publication of this quarterly journal. Throughout its eight issues, *Humanitas* has maintained an admirably high standard. It is edited by a joint board of university students and teachers, under the chairmanship of Prof. M. Polanyi. Its contributors include Bertrand Russell, D. M. MacKinnon, C. V. Wedgwood, Sherwood Taylor, C. F. von Weizsäcker, Storm Jameson and Dorothy Emmet. In its scope it embraces the philosophy of science and history, and questions of religion and education. Its purpose is to awaken interest in the moral and social responsibilities of scholarship. The autumn number is notable because it contains a full text of the recent broadcast between Bertrand Russell and Father Copleston. *Humanitas* may be obtained from Dr. W. Schenk, University College, Exeter.

Colonial Service : Recent Appointments

THE following appointments in the Colonial Service have been announced: H. A. Fooks, temporary assistant conservator of forests, Nigeria; T. Geddie, agricultural superintendent, Nigeria; T. O. Ellis (agricultural chemist, Jamaica), senior agricultural chemist, Jamaica; J. C. Eyre (senior agricultural officer, Palestine), deputy director of agriculture, Northern Rhodesia; B. G. Owen (senior agricultural officer, Nigeria), assistant director of agriculture (produce inspection), Nigeria; R. M. Harley (assistant conservator of forests, Gold Coast), senior assistant conservator of forests, Gold Coast; R. G. Hiller (senior assistant conservator of forests, Northern Rhodesia), senior assistant conservator of forests, Uganda; A. C. Russell (assistant conservator of forests, Gold Coast), senior assistant conservator of forests, Gold Coast; C. J. Taylor (assistant conservator of forests, Gold Coast), senior assistant conservator of forests, Gold Coast; N. F. Bowers (development officer, Nigeria), field officer, West African trypanosomiasis research, Nigeria. The following have been appointed assistant conservators of forests in the countries mentioned: A. E. Beveridge (Federation of Malaya), W. Carmichael (Tanganyika), D. G. Cumming (Northern Rhodesia), J. Grant (Sarawak).

British Social Hygiene Council : Summer Schools

THE British Social Hygiene Council is arranging two summer schools this year, one in England, the other in Switzerland. The first will be held at 'Elfinsward', Haywards Heath, Sussex, during August 1–14, and the second at the University of Berne, during August 17–September 1.

The course at 'Elfinsward', which will be entitled "The Teaching of Biology", is intended primarily, though not exclusively, for teachers in secondary modern schools and of junior forms in grammar schools. The director of the School will be Mr. W. L. Sumner, of the University of Nottingham. The fee, including registration, is £15 15s. In the Swiss Summer School, which will have as its theme "The Family and the Nation", an attempt is being made to cater for the needs of social workers who are interested in the family. It should appeal especially to children's officers, probation officers, magistrates, health visitors, almoners, nurses and teachers, though members of the general public will be equally welcome. The cost, including travel, hotel accommodation and tuition, will be approximately £34. Further information can be obtained from the Secretary, British Social Hygiene Council, Tavistock House North, Tavistock Square, London, W.C.1.

Summer School in Micro-Chemical Techniques

A COURSE in micro-chemical techniques will be held at the Queen's University, Belfast, during June 20–July 2, for the third successive year. Instruction will be given in centigram and milligram techniques which are of general use in various branches of inorganic and physical chemistry. Operations such as micro-electrolysis, chromatography and chemical microscopy, which are of increasing importance in diverse fields, are optional. In addition, exercises in microgram analysis will be available for specialists.

Announcements

PROF. LINUS PAULING, professor of chemistry at the California Institute of Technology, Pasadena, and M. Henri Besaire have been elected *correspondants* for the Section of Mineralogy of the Paris Academy of Sciences, in succession to the late J. C. de Lapparent and M. Leriche.

SIR NOEL ASHBRIDGE, director of technical services of the B.B.C., and Mr. H. Bishop, chief engineer of the B.B.C., will deliver the Faraday Lecture of the Institution of Electrical Engineers on February 16, at 6.30 p.m. They will speak on "Television", and will give demonstrations and experiments. The lecture will be delivered at the Central Hall, Westminster, London, and admission will be by ticket, obtainable on application to the Secretary, Institution of Electrical Engineers, Savoy Place, Victoria Embankment, London, W.C.2. The Lecture is also to be delivered at various towns throughout the country.

THE University of London has arranged a course of three lectures on "The Application of Atomic Piles in Nuclear Physics", to be delivered by Sir John Cockcroft. The lectures will be given at the Senate House, on February 2, 9 and 16, 1949, at 5.30 p.m. Admission is free and without ticket.

Two full-day conferences on "Combined Heat and Power Supplies" have been arranged by the Institute of Fuel and will be held at the Institution of Mechanical Engineers on January 25 and April 27. The conferences will be open to the public, but admission is by ticket only, to be obtained from the Secretary, Institute of Fuel, 18 Devonshire Street, London, W.1.

MARCONI INSTRUMENTS, LTD., are showing a wide range of industrial measuring instruments at their London showroom, 109 Eaton Square, S.W.1, during March 14–25, and all interested in electronics and process control are invited to apply for admission tickets either to Marconi Instruments, Ltd., St. Albans, Herts, or the London showroom.

The Cecil Peace Prize of £100 is open to all members (less than twenty-five years old) of the universities of the United Kingdom. The subject for the year 1949 is: "What international action should be taken with regard to the many millions of displaced or expelled persons and refugees in Western Europe, with a view to both the restoration of European economy and to the utilization of labour power now running to waste". Essays must be sent before November 1 to the Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1.

THE Operational Research Club (see *Nature*, October 23, p. 646) announces a change of address. The address of the honorary secretary, Mr. D. Neville-Jones, is now 14 Sheen Gate Gardens, East Sheen, London, S.W.14.

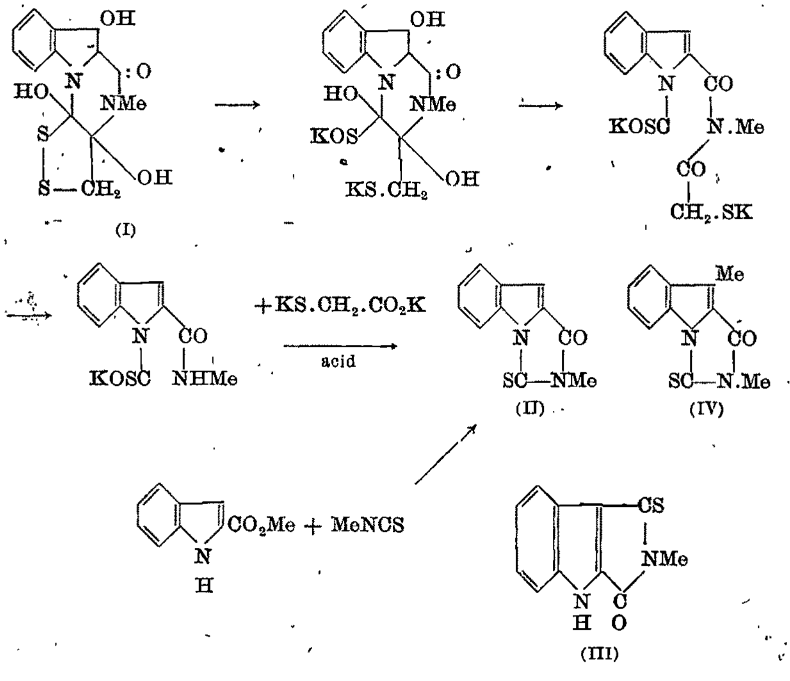
Synthesis of a Sulphur-containing Degradation Product from Gliotoxin

GLIOTOXIN, a potent fungicide isolated from culture filtrates of *Gliocladium fimbriatum*, *Trichoderma viride* and other organisms[1], has been extensively examined by J. R. Johnson and his colleagues[2], who ascribe to it the provisional structure (I). The presence of the pyrazinoindole nucleus and of the disulphide grouping appear to be established with reasonable certainty. The points of attachment of the disulphide grouping to the pyrazinoindole nucleus, on the other hand, merit further confirmation. Treatment of gliotoxin with methanolic potassium hydroxide followed by acidification of the reaction mixture gives a sulphur-containing product, m.p. 188°, which appears to have the molecular formula $C_{11}H_8ON_2S$ and for which the thiohydantoin structure (II) has been suggested[3].

Interaction of methyl indole-2-carboxylate and methyl *iso*thiocyanate gives a product, $C_{11}H_8ON_2S$, m.p. 189°, which is identical with the compound obtained from gliotoxin. In view of the reactivity of the 3-position in the indole ring system, it is possible to formulate the reaction product, $C_{11}H_8ON_2S$, from methyl indole-2-carboxylate and methyl *iso*thiocyanate as either (II) or (III). The latter structure has been excluded since we find that methyl 3-methylindole-2-carboxylate reacts with methyl *iso*thiocyanate to yield the thiohydantoin (IV), the ultra-violet absorption spectrum of which is virtually identical with that of the synthetic compound, m.p. 189°. Furthermore, methyl 1-methylindole-2-carboxylate failed to react with methyl *iso*thiocyanate. We conclude that the degradation product from gliotoxin is 2-thio-1-methylindolo-1′ : 2′-3 : 4-hydantoin (II).



The identification of this degradation product affords support for the view that one point of attachment of the disulphide grouping in gliotoxin is *via* a carbon atom directly linked to the indole nitrogen. The mechanism of formation of the thiohydantoin from gliotoxin, involving a contraction of a six- to a five-membered ring, may be represented by the accompanying scheme; this has the merit that it requires the observed alkali consumption, and is in accord with the fact that the thiohydantoin is not a primary product of the degradation of gliotoxin with alkali but that it is produced following the acidification of the reaction mixture.

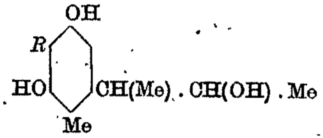
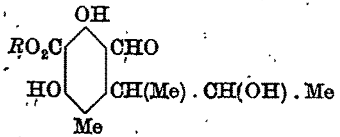
A Synthesis of Citrinin

FOLLOWING upon the development of a new structural formula for citrinin described in a communication[1] submitted to *Nature* on March 17, 1948, we have now been able to effect a synthesis of citrinin, thereby confirming our earlier deductions.

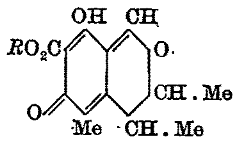
By means of a carboxylation process with potassium hydrogen carbonate and glycerol at 150°, phenol '*A*' (i, $R = H$) was converted into the carboxylic acid (i, $R = CO_2H$), m.p. 185° (decomp.). From its method of formation[2] and its ferric reaction, it is clear that the latter compound is a γ-resorcylic acid and not the isomeric β-resorcylic acid, a conclusion confirmed by the ultimate success of our synthesis. The application of the Gattermann reaction to the acid (i, $R = CO_2H$) or its methyl ester (i, $R = CO_2Me$) gave rise to formyl derivatives (ii, $R = H$) and (ii, $R = Me$) which, on treatment with concentrated sulphuric acid at room temperature for a short time, were converted, without racemization, respectively into citrinin (iii, $R = H$), m.p. 175° (decomp.), $[\alpha]_D^{18^\circ}$ − 37·4° (*c.* 1·15 gm. in ethanol) and its methyl ester (iii, $R = Me$), m.p. 139° (decomp.). The synthetical compounds were identical in every way with the natural substances and, further, the synthetical ester exhibited all the characteristic properties of the natural derivative. Similarly, starting with phenol '*B*', the optically inactive isomeride of '*A*', we have also synthesized an optically inactive citrinin, m.p. 175° (decomp.).

In connexion with the synthetical formation of citrinin from phenol '*A*' it may be noted that a synthesis of the dimethyl ether of '*A*' has already been achieved by way of the optically inactive di-





II



III

methyl ether of phenol '*B*', and also that the dimethyl ether of phenol '*A*' has now been demethylated (with accompanying racemization) to give phenol '*B*'. Consequently, the only remaining step required for the complete synthesis of optically active citrinin from *o*-toluic acid is the resolution of phenol '*B*', a project which is at present in progress in these laboratories.

It is now clear that the results of the analytical and synthetical work carried out in these laboratories completely invalidate the structure proposed more recently for citrinin by Gore *et al.*[3], and, further, also establish the misleading nature of the evidence as to constitution which these authors[4] claim from a study of the behaviour of citrinin towards diazonium salts.

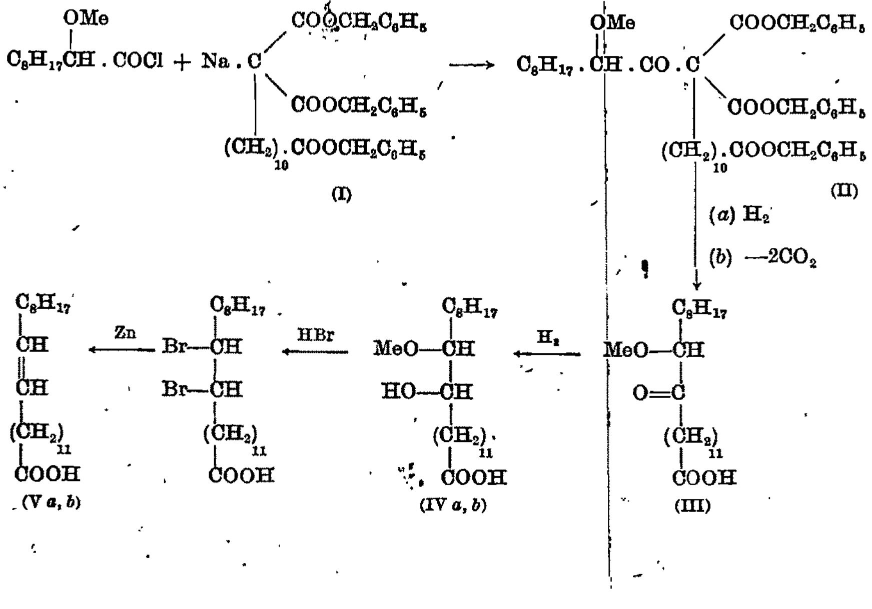
Synthesis of Erucic and Brassidic Acids

THE recent publication[1] of a new method for the synthesis of the naturally occurring unsaturated fatty acids, by way of the analogous acetylenic compounds, prompts an early report of similar work carried out in these laboratories employing the following route:



(I) (II) (III) (IV *a, b*) (V *a, b*)

In this manner the total synthesis of erucic and brassidic acids has been achieved.

Sodio tribenzyl undecane-1:1:11-tricarboxylate (I), prepared from the corresponding sodio triethyl ester in benzene solution by treatment with benzyl alcohol (3 mol.) and removal of ethanol azeotropically, yielded on condensation with α-methoxycapryl chloride a product (II) which on hydrogenolysis and decarboxylation[2] gave rise to 13-methoxyheneicosan-12-one-1-carboxylic acid (III).

Pondorf reduction of the latter furnished a solid methoxy-hydroxy-acid (IV*a*) together with a liquid product (IV*b*) thought to be a mixture of the isomers. Treatment of these materials with hydrogen bromide followed by zinc dust yielded brassidic (V*a*) and a mixture of brassidic and erucic acids (V*b*) respectively. Both acids were obtained pure by crystallization, and were found to be identical with those obtained from natural sources (m.p. and mixed m.p., *p*-bromophenacyl esters, equivalent weights and hydroxylation to the requisite dihydroxybehenic acids).

The application of this synthesis to that of other mono-ethenoid acids and more complex members of this group is under investigation and will be reported at a later date.

n-Amylpenicillin

n-AMYLPENICILLIN was first prepared in an impure state by Catch, Cook and Heilbron[1] by the catalytic hydrogenation of Δ^2-pentenylpenicillin, the product being characterized by conversion to the penillic acid and by the identification of *n*-caproic acid among the products of hydrolysis of the latter substance. The presence of *n*-amylpenicillin in the mixture of penicillins formed by the submerged fermentation of *P. chrysogenum Q* 176 has also been reported; but the isolation of the pure penicillin has not yet been recorded. This penicillin has now been isolated in the pure state and characterized.

The separation from the other penicillins was achieved by partition chromatography of the salts of the penicillins with N-ethylhexamethyleneimine, using water adsorbed on silica gel as the stationary phase and wet ethyl acetate as the moving phase.

Microchromatographic assay by the method of Goodall and Levi[2] confirmed that the penicillin was free from contamination by other penicillins. By biological assay, using sodium benzylpenicillin as the standard, the potency of the sodium salt was 1,680 u./mgm. when tested against *S. aureus* (N.C.T.C. 6571) by the turbidimetric method, 1,670 u./mgm. when tested against *S. aureus* (N.R.R.L. 313) by the cylinder plate method, and 660 u./mgm. when tested against a strain of *B. subtilis* by the cylinder plate method. Thus *n*-amylpenicillin has a *B. subtilis* : *S. aureus* assay ratio of 0·39.

Sodium *n*-amylpenicillin crystallizes in the form of flat, blunt-ended needles, with one molecule of water of crystallization from moist acetone or moist ethyl acetate. The anhydrous salt rapidly takes up one molecule of water on exposure to atmospheric moisture, and, on account of this, accurate analysis of the sodium salt was difficult. A sample of sodium *n*-amylpenicillin which had been dried *in vacuo* over phosphorus pentoxide at 100° C. gave: C, 49·5 ; H, 6·3 ; N, 8·7 per cent (calculated for $C_{14}H_{21}O_4N_2SNa$: C, 50·0 ; H, 6·25 ; N, 8·34 per cent). The anhydrous salt had a melting point of 188° C. (decomposition) and $[\alpha]_D^{23}$ 319° ($c = 1$ per cent in water).

Conversion of *n*-amylpenicillin to the isomeric penillic acid gave a product which crystallized from warm methanol as stout rods of melting point 182° C. and $[\alpha]_D^{23}$ 534° (at a concentration of 0·5 per cent in decinormal sodium carbonate). Recrystallization from aqueous methanol gave crystals of a hydrate. The anhydrous acid was not hygroscopic. Found : C, 53·2 ; H, 7·14 ; N, 8·90 per cent ; calc. for $C_{14}H_{22}O_4N_2S$: C, 53·5 ; H, 7·00 ; N, 8·92 per cent. X-ray powder photographs of the penillic acid gave results practically identical with those obtained by Mrs. D. Hodgkin from the sample prepared by Catch, Cook and Heilbron.

The constitution of the penicillin was established by acid hydrolysis and identification of the *n*-caproic acid produced as its *p*-toluidide and *p*-bromphenacyl ester.

Variations in Force Constants

IN general, small variations in a given force constant in different molecules cannot be accepted as having any absolute significance. This is obvious when we consider how the value of any particular force constant in a polyatomic molecule is obtained[1]; usually, as many constants as possible are carried over from related molecules, and the whole set adjusted to fit the observed vibration frequencies. The final values will depend on the force field used ; the usual convention is to introduce an interaction term into the potential energy expression whenever any large adjustment becomes necessary which cannot be correlated with the structural features, for example, the presence of bonds of intermediate type, due to resonance.

Related to the general problem is the question of group frequencies ; here we have vibrations largely localized within a particular chemical grouping (or, in some instances, a linkage), which remain comparatively unaffected by changes in the molecular residue. Small variations in a group frequency may be due to changes in the overlapping coupling co-ordinates, and therefore, in general, cannot be employed to measure variations in the main constant for the group vibration.

It is of considerable interest that by applying a general normal co-ordinate treatment to the non-planar group of vibrations of related series of substituted ethylenes, it has been found possible to obtain consistent sets of small variations in the force constants for the non-planar bending motions, and to correlate these variations with the observed shifts in the group frequencies and with the electro-negativities and electron-donating powers of the substituents[2]. From calculations on twelve compounds, a linear relation between the CH_2 bending constant (f_{CH_2}) and the corresponding group frequency (δ_{CH_2}) is obtained, and used to fit a further nine compounds into the series. Substitution by CH_3., CH_3.CO.O., and the halogens leads to a decrease in f_{CH_2} compared with its 'neutral' value in ethylene ; the increment in $CH_2 : CX_2$ is greater than in $CH_2 : CHX$ for all the examples studied, and increases with the electro-negativity of the substituent X, being particularly large for fluorine. Substitution by .CN and .CO.OMe leads to positive increments.

These facts suggest that the main effect operative is analogous to the electromeric (resonance) effect directing aromatic substitution ; the powers of conjugation of vinyl and phenyl are known to be approximately equal. CH_3., CH_3.CO.O. and the halogens lead to *o*- and *p*-substitution, and .CN and .CO.OMe to *m*-substitution. Thus, withdrawal of electrons from the terminal carbon atom of the vinyl group results in an increase in the forces opposing non-planar bending of the $=CH_2$ group. The relatively high value of f_{CH_2} in formaldehyde can then be explained by the fact that this molecule is a resonance hybrid in which the ionic structure $\overset{+}{C}H_2—\overset{-}{O}$ is of considerable importance. The low value of f_{CH_2} in allene suggests that this is also a resonance hybrid, with contributions from ionic structures $\overset{-}{C}H_2—\overset{+}{C}=CH_2$, $CH_2=\overset{+}{C}—\overset{-}{C}H_2$. In the allyl halides the resonance effect is inhibited by the $—CH_2—$ group, and the order of the frequencies δ_{CH_2} is the reverse of that in the vinyl halides. The chloride lies roughly midway between propylene and ethylene, agreeing with the fact that in $\varphi CHCl_2$ there is no appreciable difference in the reactivity at the *o*-, *p*- and *m*-carbon atoms.

The resonance effect cannot operate directly on the odd C—H bond in $CH_2 : CHX$; the bending constant f_{CH} decreases as the electro-negativity of the substituent X increases, .CN now lying between CH_3. and Cl., and the effect again being particularly large for fluorine. The values of f_{CH} in acetylene and benzene (non-planar) suggest that there may be an inverse relation between the constants for C—C stretching and for bending of the adjacent C—H bonds.

A full account of this work, including a detailed treatment of problems arising from the solution of the secular equations, is to be published elsewhere[2].

Metabolism of Nicotinic Acid by Infants

THE recent work of Knox and Grossman[1] has shown the existence of a new metabolite of nicotinic acid. They produced evidence that N-methylnicotinamide was oxidized by enzymes in the liver of the rabbit to N-methyl-2-pyridone-5-carboxylamide, and isolated that compound from the urine of human subjects who had been given daily doses of 0·6–0·9 gm. nicotinamide.

A method[2] for the estimation of N-methyl-2-pyridone-5-carboxylamide in human urine has recently been worked out and has been applied to urines from adults and new-born children. 24-hour specimens were obtained from the adults, and the total amounts of urine passed by the children in the first 72 hours of life were collected. The results of the analysis of these urines are shown in the accompanying table.

Urinary excretion of N-methylnicotinamide and of N-methyl-2-pyridone-5-carboxylamide by newborn infants and by adults

Urine specimen	Subject No.	Total urinary output (mgm.) N-methyl-nicotin-amide (NM)	Total urinary output (mgm.) N-methyl-2-pyridone-5-carboxylamide (P)	$\frac{P}{NM}$
Infants (total excretion in first 3 days after birth)	1	5·3	1·7	0·3
	2	4·7	1·6	0·3
	3	4·3	1·0	0·2
	4	7·1	2·1	0·3
Mean		5·4	1·6	0·3
Adults (24-hr. specimens)	1	8·9	12·5	1·4
	2	7·3	11·9	1·6
	3	7·4	10·8	1·5
	4	5·5	14·9	2·7
Mean		7·3	12·5	1·8

It is clear that the ratio of the pyridone to N-methylnicotinamide was much lower in the urine of the infants than in the urine of the adults. This suggests that the rate of enzyme activity in the infant was much lower than in the adult, and offers an explanation of the very high urinary excretion of N-methylnicotinamide in the first days of life reported by Hamil, Coryell, Roderuck, Kaucher, Moyer, Harris and Williams[3]. The results of these workers have in this respect been confirmed in the course of the present investigation.

Bile Pigments from Normal Erythrocytes

Gardikas, Kench and Wilkinson[1] have found that treatment of human erythrocytes with acetic acid in an oxygen-free atmosphere, in the absence of ascorbic acid, did not yield any biliverdin when the ether solution was extracted with 5 per cent hydrochloric acid. They claim that the bile pigments isolated by Lemberg and co-workers[2,3] from human and sheep erythrocytes, and from horse oxyhæmoglobin, may have arisen as an artefact from choleglobin, the latter being formed from oxyhæmoglobin by the action of ascorbic acid; ascorbic acid had been added in these experiments to prevent the oxidation of biliverdin to bilipurpurin. They have overlooked, however, that bile pigments had been obtained in an even somewhat higher yield without the addition of ascorbic acid, and also from horse carboxyhæmoglobin[2]. The yield is also unaltered if ascorbic acid is added together with the acetic acid, instead of being added immediately before acidification.

I have now repeated the experiments with sheep and human erythrocytes in the absence of ascorbic acid and of oxygen, removing oxygen either by evacuation or by carbon monoxide. In both instances the total bile pigment yield was 7–9 μgm. per ml. of human or sheep erythrocytes. Little biliverdin is found under these conditions, the main product being a weak-basic bilipurpurin, which is extracted from ether by 20 per cent hydrochloric acid.

In order to allow other workers to repeat these experiments, the method of isolation is given in detail.

After removal of oxygen by exhaustion or by repeated saturation with carbon monoxide, 10 ml. of erythrocytes are treated with 50 ml. of 80 per cent acetic acid; after standing for 15 min. at room temperature, the solution is diluted with 120 ml. of peroxide-free ether. Up to this point, the whole procedure is carried out in an oxygen-free atmosphere. The precipitated protein is now filtered off, and the ether solution is washed five times with an equal volume of water with cautious shaking. The first three washings are re-extracted with small amounts of ether, which are added to the main bulk of the ether solution. The hæmatin, which at this stage begins to precipitate, is removed by filtration through thin filter paper (Munktell, No. 1*F*), and the filtrate is washed once more with water.

This solution is fractionated as follows. Three extractions with 10 per cent hydrochloric acid (3 ml. each) yield a somewhat cloudy extract, which is cleared by washing three to four times with small volumes of ether with the addition of some glacial acetic acid. This 10 per cent hydrochloric acid extract is faintly green and contains a little biliverdin. The ether solution remaining after these extractions is now extracted three times with 20 per cent hydrochloric acid (5 ml. each). This extract is cleared and freed from emulsified hæmin by washing with ether and acetic acid. It is blue to blue-violet and contains mostly bilipurpurin. Finally, the remaining ether solution is extracted once again in the same manner with the same volume of 20 per cent hydrochloric acid. The cleared extract is faintly yellow and serves as a blank for the bilipurpurin estimation. The solutions are analysed in the spectrophotometer in 6-cm. tubes as described by Lemberg and coworkers (see ref. 2, p. 370, method III). The fact that the second extraction with 20 per cent hydrochloric acid does not yield any bile pigment shows that this is not derived from the hæmin.

These experiments prove that the bile pigments thus isolated are derived from a precursor present in the erythrocytes, not from hæmoglobin.

Reduction of Tetrazolium Salts by some Biological Agents

TETRAZOLIUM salts, first prepared by Pechmann and Runge[1], have attracted the interest of workers in biological fields since the demonstration by Kuhn and Jerchel[2] that living organisms such as yeast, garden cress and bacteria have the power of reducing the colourless, soluble tetrazolium salts to red, insoluble formazan compounds, reduction taking place in neutral solution and the cells taking up the colour. Mattson *et al.*[3] confirmed these results and showed that a similar reaction was given by many other viable tissues of both plant and animal origin; they suggested that reduction is due to dehydrogenase systems requiring co-enzymes I or II. Straus *et al.*[4] applied the test to normal and neoplastic human tissues. They argued that, as malignant tumours show an increased glycolytic activity, their reducing power for tetrazolium salts might also be augmented. These authors claim that this hypothesis is confirmed by their initial results.

It would obviously be of importance to possess a simple method of establishing the viability of tissues. The following experiments were made in order to decide whether the reduction of tetrazolium salts is restricted to living tissues. Triphenyl tetrazolium chloride was prepared in this department by Dr. D. H. Marrian by the method of Mattson (personal communication). Preliminary experiments confirmed that a 1 per cent solution was readily reduced by many plant tissues, and by human leucocytes and mouse liver, brain, kidney, striped muscle, cartilage and mammary carcinoma.

Fresh brewers' yeast rapidly reduced the salt, the reaction being completely inhibited by heating to 60° for three periods of ten minutes. The yeast was not inactivated by suspension in acetone or absolute alcohol for two periods of one half-hour and subsequent drying, or by air-drying. Air-dried yeast remained active after seven months, as did acetone-dried mushrooms after four months. A seven-year-old sample of air-dried yeast had lost its reducing power.

Yeast extract (Lebedew) was prepared by air-drying fresh yeast, incubating it at 37° in three volumes of distilled water for two hours, and filtering at 5°. The extract was cell-free, apart from a few bacilli; it rapidly reduced triphenyl tetrazolium chloride and preserved its activity when precipitated with absolute alcohol and ether and dried. It was inactivated by heating to 60° for two periods of ten minutes. Dialysing for 2–24 hours abolished its reducing power, but this could be restored by adding phosphate and glucose, or boiled undialysed extract, or concentrated dialysate; it was lost after dialysing for 70 hours, without being restored by the addition of phosphate, glucose, co-enzyme I, adenosine triphosphate and magnesium ions. The reaction given by fresh yeast extract was not inhibited by *M*/90 iodo-acetate, potassium cyanide or sodium fluoride, but slowed by *M*/60 iodo-acetate. Reduction proceeded in the absence of fermentation and was not accelerated by its presence, as shown in the accompanying table. (Experiments done at 37° in phosphate buffer at *p*H 7·4.)

Although reduction occurred without a concomitant fermentation of glucose, its onset was accelerated when glucose was added to dialysed extract, the effect being independent of glucose concentration within the range 3–150 mgm./per cent. In this reaction, glucose could be replaced by galactose, mannose, raffinose or xylose, but not by dulcite, inosite, salicin or mannitol.

Expt. No.	Nature of sample	Reduction first visible (min.)	Glucose concentration (mgm./per cent)		Fermentation
			Initial	After 30 min.	
1	Yeast extract	2½	202	199	Absent
2	Dried yeast	2	134	163	Absent
3	Fresh yeast	2	243	134	Present

The experiments show that tetrazolium salts can be reduced by non-viable cells and by cell-free extracts, and that reduction in yeast is independent of fermentation.

I am indebted to Dr. E. Friedmann for his advice in the planning of these experiments.

Plasma Cells in the Reaction against Rabbit Tissue Homografts

THE well-known correlation between the breakdown of homografts and their invasion by lymphocytes[1,2] has acquired new interest because of current views on the role of lymphocytes in the manufacture and transport of antibodies[3]. It has been shown that the breakdown of homografts results from a process of active immunization of the host[4]; and since there has been a failure to demonstrate appreciable antibody in the serum[5], it seemed probable that the lymphocytes were the instruments of destruction. More recently, plasma cells have been put forward as producers of antibody[6,7], and this hypothesis suggested a search for these cells in homografts by employing the Unna–Pappenheim stain (methyl green pyronin). With routine staining methods only a few mature plasma cells were identified among the lymphocytes in the period before graft breakdown.

Grafts of submaxillary gland were implanted intradermally (six per rabbit), and one excised together with its surrounding skin every fourth day thereafter and fixed in mercuric chloride-formalin.

In sections stained with methyl green pyronin, the invading cells were found to include, besides true lymphocytes, a large number of cells staining strongly with the pyronin. The latter were of several varieties: (1) Large cells of reticular aspect corresponding to Fagræus's "transitional cells" as found in the spleen. These have large, lightly stained nuclei with reddish nucleoli and moderately red cytoplasm. They are not numerous. (2) Cells resembling the foregoing type but smaller and occasionally with more chromatin in their nuclei. These correspond to Fagræus's "immature plasma cells"; they are not numerous in most grafts. (3) Cells resembling lymphocytes but with cytoplasm staining red, often with the same intensity as mature plasma cells. They include the small, medium and, less commonly, large lymphocytes (the standard by which the various sizes of lymphocyte were judged was that of Maximow and Bloom's "Textbook of Histology", 4th ed.; the greater amount and density of the chromatin in the lymphocytes were taken to distinguish them from reticular cells). They are more numerous than the reticular type of cell. (4) Cells which are intermediate in appearance between the three foregoing classes and mature plasma cells. These are the most numerous. (5) Forms with two and occasionally more nuclei; they are numerous in some specimens. (6) Mature plasma cells as typified by a low nucleus to cycloplasm ratio, eccentricity of the nucleus, and cytoplasm which stains deeply red and usually has the characteristic 'clear area'.

On the fourth day after implantation, very few invading cells are present in the graft. However, large numbers are present on the eighth day when breakdown of the graft epithelium is about to start and the graft blood vessels are greatly dilated and engorged. Preliminary cell counts give one pyronin-stained cell for every two or three unstained lymphocytes; the latter are nearly all small lymphocytes with cytoplasm either invisible or so faintly stained as to be just seen. Among the pyronin-stained cells mature plasma cells are outnumbered by immature ones. Reticular-type cells are usually few, although in a small minority of specimens they are abundant.

On the twelfth day, when much of the graft epithelium has already been destroyed and vascular breakdown is widespread, there is no significant change in the proportion of pyronin-stained cells relative to unstained lymphocytes. However, among the pyronin-stained cells the proportion of mature plasma cells has increased so that they equal or outnumber the immature forms. By the sixteenth day, when destruction of the graft epithelium is complete, mature plasma cells are in a clear majority. Even fewer cells of the reticular type were found in these later stages than on the eighth day. Grafts placed in an animal which had been sensitized by means of six grafts from the same donor twenty-four days previously were similarly invaded; but the proportion of pyronin-stained cells was higher than in the corresponding grafts of the first set of six, and graft breakdown occurred earlier.

The graft blood vessels contained a few pyronin-stained cells: those resembling lymphocytes (category (3) above) and cells intermediate between them and mature plasma cells; occasionally a reticular-type cell was found. Unstained lymphocytes and monocytes were more numerous. Mature plasma cells were not found inside the vessels, although their perivascular accumulation was a striking feature of the grafts.

Mitotic figures were not uncommon in the pyronin-stained cells, mainly in those which appeared to be of the medium lymphocyte type; they were also found in some which appeared to be the "transitional cells" of the Fagræus classification.

While recognizing the pitfalls in tracing cellular life-histories from transitional stages, nevertheless use of the serial biopsy technique makes it reasonable to infer that development of plasma cells, at least in its later stages, takes place in these homografts; and while consistent with the view that plasma cells develop from reticular cells, these observations seem to lend equal support to the view that they develop from lymphocytes. There is no evidence, however, that lymphocytes which arrive at the graft in a non-pyronin-stainable condition develop into plasma cells: it is conceivable that only those which arrive in a stainable condition, indicative of a modification undergone elsewhere, can so develop.

Entamœba muris: a Complicating Factor in the Experimental Infection of Rats with *E. histolytica*

The introduction of the young rat as an experimental host for *Entamœba histolytica* in the investigation of amœbicidal substances[1,2] has made the study of natural amœbic infections of rodents of great importance. Adequate descriptions of these do not exist. Fulton and Joyner[3] have recently directed attention to this problem, but their descriptions are incomplete.

I have made a study of the morphology and host-parasite relationships of *E. muris* found in rats and mice which will be published elsewhere. The main details will be summarized here, in order to clarify the position.

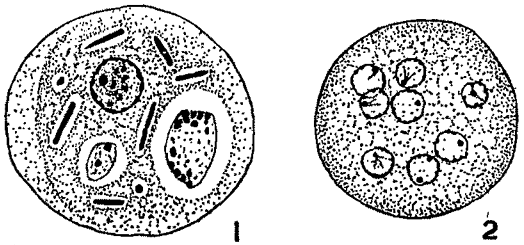
The trophic amœbæ of *E. muris* measure 12–30 μ in diameter, and move by protrusion of pronounced ectoplasmic pseudopodia; food vacuoles contain bacteria, intestinal debris, or other protozoa. When stained, the nucleus is seen as a vesicular structure, with a peripheral layer of chromatin granules, equal in size and distributed evenly over the whole surface, the karyosome being typically eccentric in position.

The amœba encysts in the cæcum and passes out of the host with the fæces. Immature cysts usually contain a large glycogen vacuole. The mature cysts contain eight nuclei and usually measure 13–18 μ in diameter. Chromatoid bodies are not commonly present in the ripe cysts, but when observed were usually bar-shaped with irregular ends. The structure of the cystic nuclei is similar to that of the nucleus of the trophic amœba.

E. muris is morphologically identical to *E. coli* of man. It is distinguished from *E. histolytica* by: (*a*) the eccentric position of the karyosome, (*b*) the cysts containing eight nuclei (see accompanying illustration).

The amœbæ in infected mice were morphologically identical with those in rats, and their cysts were infective to rats. The organism is non-pathogenic, since no lesions were discovered in the alimentary canal of infected animals. An infection of hamsters by a similar species was also shown to be infective to rats[4]. It is likely that infections in other laboratory rodents are closely related to *E. muris*.

It was not possible to cultivate the amœbæ in Dobell and Laidlaw's[5] or other culture media.



E. muris from rat. Fixed in Schaudinn's fluid, stained in iron hæmatoxylin, × 1,500. (1) Trophic amœba. (2) Mature cyst

The effect of emetine hydrochloride and carbarsone was determined upon experimental infections of *E. muris* in rats. The rats, which were of an age similar to those used for routine *E. histolytica* experiments, were infected with *E. muris* by administering orally a suspension of mature cysts, each rat receiving ten to twenty cysts. The drugs were given, mixed in a known percentage with the dry mash diet, at a dose-level known to be therapeutically effective against *E. histolytica*. The rats were fed with the drug diet immediately after infection with *E. muris*, and were killed after six days continuous feeding with this diet.

Effect of emetine hydrochloride and carbarsone upon *E. muris* in the rat

Drug	Drug in the diet (per cent)	Proportion of rats positive for *E. muris*
Emetine hydrochloride	0·008 0·004	2/3 5/6
Carbarsone	0·4	3/5
Controls		8/11

The accompanying table shows that although not all of the rats inoculated became infected, neither of these drugs had any significant action *in vivo* upon *E. muris*. The highest dose of emetine hydrochloride was toxic to the rats. Hegner and Eskridge[6] found that a single dose of 1 gm./kgm. of carbarsone freed rats from infection with trichomonads, but had no effect upon *E. muris*.

It is important in experiments in which rats are used for experimental infections with *E. histolytica* to make sure that the results are not rendered valueless by the presence of *E. muris*. This may be ensured by the selection and care of the animals used. Rats should be aged eighteen to twenty-one days, since at this age they have not commenced to ingest solid food, and are most susceptible to infection with *E. histolytica*. The animals should be bedded upon sterile wood wool, and suitable precautions taken to prevent contamination by other laboratory rodents. The cæca of rats of this age are small, of a pink colour, and contain mucus, but no food particles or protozoa. Microscopic examination showed the presence of desquamated tissue cells, which superficially resembled amœbæ, but were generally smaller, were motionless, and could be distinguished from amœbæ with certainty by examination of stained films. Rats bought in the open market are seldom suitable, as the conditions are difficult to control, and rats of this age are difficult to transport satisfactorily.

Work upon experimental amœbiasis in rats has many pitfalls, and requires a supply of rats which are bred under controlled conditions, together with the collaboration of a protozoologist.

I should like to thank Miss S. I. Pluthero for technical assistance.

Relationship Between the Average Carcase Weight of Rams, Ewes and Lambs

FROM a statistical analysis of the returns of the twenty-five Ministry of Food collecting centres in West Wales for the four years 1943–46, it has been found that the regression equation of the average lamb carcase weight ($X1$) on the average carcase weights of ewes ($X2$) and rams ($X3$) is:

$$X1 = 3{\cdot}42 + 0{\cdot}511\,X2 + 0{\cdot}125\,X3.$$

These estimated weights of lambs ($X1$) fit closely to the observed weights (estimated dressed carcase weight) according to the χ^2 test.

An equally close fit was obtained from the empirical equation:

$$R + E = \Pi L,$$

while a good fit was given by

$$R + E = 3L,$$

where R, E and L stand for the estimated dressed carcase weight of rams, ewes and lambs respectively.

The above expressions have been obtained from the analyses of the returns for more than half a million lambs, approximately 70,000 ewes and nearly 6,000 rams, and they show remarkable agreement for a wide range of estimated dressed carcase weights, as determined by the graders of the Ministry of Food. Warman[1] has shown that the estimated dressed carcase weights have been very close to the actual carcase weights after slaughter.

In West Wales the ranges in estimated dressed carcase weights at different centres have been as follow: rams, 51·9–91·5 lb.; ewes, 38·1–69·5 lb.; and lambs, 28·3–52·6 lb.

On the assumption that the average weight of the progeny at maturity is equal to that of the mean of the parents, then the above formulæ imply that producers sell their fat lambs when they attain 63·6–66·6 per cent maturity.

There is evidence of a definite stratification of the sheep industry in this region in both time and space, and it would appear that it can be correlated with variations in climatic conditions. The details of this study will shortly be ready for publication elsewhere.

This investigation has formed part of a survey of animal health and production in West Wales, and thanks are due to the scientific branch of Messrs. Cooper, McDougall and Robertson, Berkhamsted, for financial support. Grateful acknowledgment is also made to Mr. Percy George, for the assistance he has given with the statistical analysis.

Sulphur-containing Amino-Acids in the Rumen Bacteria of Sheep

As part of the investigations proceeding in this laboratory on the physiology and nutrition of sheep, the cyst(e)ine (cystine plus cysteine, calculated as cystine) and methionine contents of two large samples of mixed rumen bacteria were determined. The samples were obtained from slaughterhouse rumens selected to represent sheep from 'dry' and 'green' feed conditions respectively, the absence of green material in the rumen being taken to indicate 'dry'-fed and its presence to indicate 'green'-fed animals.

The whole rumen contents were strained into cans through several thicknesses of gauze, transported to the laboratory and chilled in a refrigerated room. The materials were then strained through cloth and centrifuged first at low speed (21,000 r.p.m.) to remove food particles, protozoa and yeast cells, then at a higher speed (34,500 r.p.m.) to throw down the bacteria. Microscopic examination showed the solid material to be practically free of food particles. The bacterial sludge was spread out in shallow dishes and dried in a hot-air oven at 50–60° C. The resulting dry samples appeared as rather dark translucent flakes and were found to be virtually free from fibre.

Representative 10-gm. samples were taken from these dried preparations and ground to pass through a 0·5-mm. sieve prior to analysis. 'Whole' protein preparations were prepared from the ground samples by the method of Lugg[1], as modified by Lugg and Weller[2]. Nitrogen determinations were made by the micro-Kjeldahl method, cyst(e)ine and methionine determinations by the differential oxidation method of Lugg[3] together with the modified procedure of Lugg and Weller[2] for total sulphur. The results are presented in the accompanying table.

No.	Protein preparations	Per cent of total nitrogen	Per cent of total nitrogen	
			Cyst. N	Meth. N
1	Rumen bacteria from sheep on 'dry' feed	8·78	1·63	1·18
2	Rumen bacteria from sheep on 'green' feed	9·62	1·50	1·54

The cyst(e)ine and methionine nitrogen contents of the preparations are expressed as percentages of the total nitrogen present, each figure being the mean of closely agreeing duplicate determinations. It is apparent that the two samples differ in certain respects. The differences in the nitrogen and cystine contents of the 'whole' protein preparations are not great; but the methionine values are significantly higher for the sheep on 'green' feed than for sheep on 'dry' feed. This difference could be due either to an effect of diet on the nature of the bacterial proteins, independent of the bacterial types, or to differences in the types of organisms comprising the two mixed samples, or to a combination of both. Further evidence on these possible alternatives is being sought. Many workers have shown, however, that changes in the nature of the diet result in qualitative as well as quantitative changes in the rumen floral population[4–7], while others have shown that the amino-acid constitution of bacterial and yeast proteins is fairly constant over a wide range of growth conditions.

Because of the inadequate methods available to early workers, reliable data for the sulphur-containing amino-acid contents of micro-organisms, with which our results may be compared, are meagre. Recently, however, Camien *et al.*[9] have reported the methionine contents of the proteins of four species of Lactobacilli and the cystine content of *L. fermenti*, and Block and Bolling[10] the cystine and methionine contents of eight strains of yeast. Our samples of rumen bacteria differ in several important respects from these. The rumen bacterial protein is, in each case, twice as rich in cystine as the yeast protein and twenty times as rich as the *L. fermenti* protein. It is also considerably richer in methionine than the protein of Lactobacilli, although not greatly different from yeast protein in this respect.

A comparison with the figures obtained from leguminous seeds, for which similar methods of estimation to ours were used[11,12], shows the rumen bacterial protein to be richer in cystine and very much richer in methionine than any of them, including the soya bean, which was the best of those examined. A similar comparison with the figures reported for such 'quality' proteins as casein and muscle protein[13] shows that our rumen bacteria contain protein similar in methionine content to these materials but very much richer in cystine.

It is apparent from these comparisons that rumen bacterial protein is rich in both cystine and methionine. This finding is of considerable importance, in view of its obvious relationship to the theory that in ruminants dietary nitrogen is largely converted to bacterial protein prior to digestion and absorption[14], and to the finding that in these animals the value of non-protein nitrogenous substances, such as urea, is greatly enhanced when supplemented with methionine[15–17].

The nutritional significance of these findings will be discussed more fully in a later publication, in conjunction with other data.

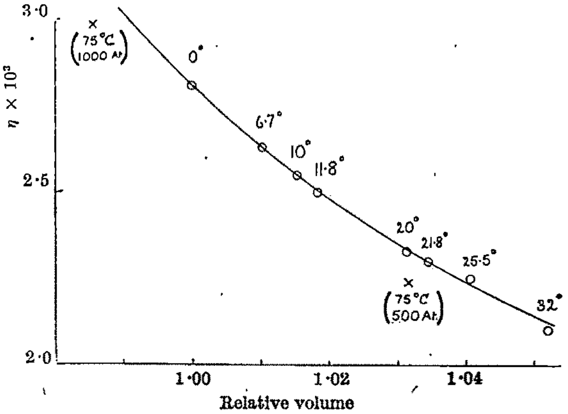
Viscosity–Volume Relation for Liquids

Dr. Jobling, in his letter published in *Nature* of October 16, states that the dependence of the viscosity of a liquid on temperature is "certainly for ether above 0° C. and probably for many other liquids" due entirely to the change of volume. That this is not so in general has often been pointed out by one of the present writers[1]. For example, for mercury (a monatomic liquid and so more suitable than ether to be cited in support of a theory of liquid viscosity) the temperature variation of viscosity at constant pressure in the range 30–75° C. is reduced only by some thirty per cent when the volume, instead of the pressure, is kept constant[2]; for *iso*amyl alcohol, working at constant volume reduces the temperature variation by some twenty-two per cent only: nowhere in the whole range of recorded experiments on carbon dioxide is the viscosity a function of the specific volume alone. Dr. Jobling also states that on Born and Green's theory the part of the viscosity that depends upon molecular attraction is a "volume effect": this, however, is not proved, or even asserted, by the authority quoted by him, and is certainly not asserted or implied by Born and Green[3]. The only experimental results that Dr. Jobling brings forward to support his contention refer to ether above 0° C. However, even for ether in the temperature-range considered, from 0° to 32°, the evidence fails.



The continuous curve shows the variation of viscosity of ether with volume at atmospheric pressure, the temperatures corresponding to the various points being indicated. The two isolated points refer to 75° C. and the pressures indicated

For ether in the region in question there exists, over and above the data for the variation of viscosity with temperature at atmospheric pressure, only one experimental point, that for 75° C., and a pressure of 500 atmospheres. The enlarged portion of Dr. Jobling's diagram, for relative volume $v = 0{\cdot}98$ to $1{\cdot}05$, which we have prepared, shows this point and also that for 75° and 1,000 atmospheres. These two points indicate a viscosity which, at a given v, is well below that at atmospheric pressure and shows no signs of progressive approach. Further, from consideration of the 30° and 75° isothermals for ether due to Bridgman[4], the ratio $\left(\frac{\partial\eta}{\partial T}\right)_v \Big/ \left(\frac{\partial\eta}{\partial T}\right)_p$ which indicates the relative importance of the variation of viscosity with temperature at constant volume and that at constant pressure, and which should be zero according to Dr. Jobling, has been plotted by us against p. This ratio diminishes in an approximately linear manner from 0·56 at 2,000 atmospheres to about 0·1 at atmospheric pressure: the plot indicates that it would not be zero until a pressure of about − 500 atmospheres was reached, and no one has so far been able to put a liquid in the state of tension indicated by this large negative pressure.

The position is, then, that, from the behaviour of one particular liquid in a restricted temperature-range, Dr. Jobling has drawn a certain conclusion about the behaviour of liquids in general—but that the behaviour of the liquid in the range in question does not, in fact, support his hypothesis.

Green's Theory of Liquid Helium

IN a recent communication[1], H. S. Green remarks that "the application of the Born–Green theory of liquids[2,3] to helium II has been completed and it has been found possible, without further assumption, to explain all the well-known properties of this liquid". A discussion of this theory must be postponed until the detailed calculations of Green are published. Nevertheless, a few remarks may be made on the basis of the preliminary communications[1,3].

The crucial point in any theory of liquid helium is the interpretation of the λ-point. In order to understand Green's ideas on this phenomenon, one must recall that—as is generally agreed—there are two essentially different molecular mechanisms responsible for the viscosity of fluids. Only the first mechanism appears in ideal gases. It consists in the transport of momentum by the thermal agitation of the molecules resulting in a so-called kinetic viscosity. In liquids there is another mechanism completely overshadowing the first. It is due to the fact that the molecules have to pass potential barriers in order to enable one liquid layer to glide over another. Thus the flow near a solid wall occurs by means of an activation process. The corresponding viscosity was called 'potential viscosity' by Born and Green[3] and 'dynamic viscosity' by Tisza[4,5]. Usually the two viscosities can be easily distinguished by their characteristic temperature dependence. The kinetic viscosity has a weak positive, the potential viscosity a strongly negative, temperature coefficient.

According to Green, the transition of helium I to helium II is due to a rapid drop in the potential viscosity. Thus helium I is supposedly a normal liquid, whereas helium II is characterized by a very small viscosity. This interpretation cannot be reconciled with experimental facts.

In the first place, the measurements of Keesom and MacWood[6] clearly show the absence of potential viscosity in both helium I and II (for a discussion of this question see ref. 5; Figs. 1 and 2 especially show the striking contrast between the viscosity of hydrogen, a classical liquid, and helium I, a quantum liquid).

A second point is that the transition from helium I to helium II cannot be described by assuming any particular value—no matter how extreme—for the viscosity of helium II. The change is more radical, and the macroscopic hydrodynamic equations themselves must be changed by going from the ordinary one-fluid hydrodynamics to a two-fluid hydrodynamics[4,5,7].

The idea of the two-fluid hydrodynamics was originally suggested by F. London's[8] well-known interpretation of the λ-point as a Bose–Einstein condensation[4]. Recently, however, it has been developed on essentially phenomenological lines[5]. This phenomenological theory allowed the correlation of experiments which appeared paradoxical from the point of view of ordinary hydrodynamics (for example, the apparently contradictory measurements of viscosity from capillary flow and the damping of an oscillating disk). Moreover, it led to numerous—sometimes rather striking—predictions which were all verified by experiment. It should here suffice to mention the long series of beautiful experiments by Kapitza[9], the temperature dependence of the moment of inertia[10], and the propagation of temperature waves (the so-called second sound)[11].

The present situation may be summed up by stating that the phenomenological theory provides a qualitatively, and partly even quantitatively, correct description of liquid helium. It is to be hoped that Green's theory with its more fundamental approach can be adjusted so as to conform to the experimental facts and to the phenomenological theory systematizing these experimental facts.

Whether or not the Bose–Einstein condensation will be incorporated into the future quantum mechanical theory is another question. Green states that "a serious objection to these theories [based on the Bose–Einstein condensation] is the occurrence of entirely analogous phenomena in superconductors, where the electrons obey Fermi statistics". Although the analogy between helium II and superconductors is very suggestive indeed, the identity of the molecular mechanisms can scarcely be considered as an established fact.

The existence of the helium-3 isotope obeying Fermi statistics provides a more reliable experimental approach to the problem of statistics. It has been recently shown that helium-3 atoms do not take part in the superflow of ordinary helium[12]. Although the definitive interpretation of this fact may have to wait until the low-temperature behaviour of pure helium 3 is known, it is perhaps premature to preclude the relevance of the Bose–Einstein condensation to superfluidity.

[12] Daunt, J. G., *et al.*, *Phys. Rev.*, **72**, 502 (1947); **73**, 1263 (1948).

I AM glad to endorse certain points which Prof. Tisza has made in his letter, especially that the behaviour of helium II cannot be explained by assuming extreme values for macroscopic parameters, and the necessity for the modification of the classical formulation of the laws of hydrodynamics and thermodynamics. It is probable that his main criticism of the rigorous theory of helium II which I have sought to develop is founded on a mistaken identification of what Prof. Born and I have called 'potential viscosity' with the 'dynamic viscosity', a rather vague concept based on an essentially classical model which was admittedly the best available until very recently. The 'potential viscosity' is for most practical purposes the difference between the viscosity of the liquid and that of the vapour at the same temperature; in helium I this has a value $\sim 15\mu$ poise, almost constant along the saturated vapour curve, as one would expect with rapidly decreasing pressure.

A detailed exposition of the application of the quantum theory of liquids to helium II has now appeared[1], and so far as I am aware it is in agreement with all of the experimental evidence. Many of the results agree with those of the two-fluid theory, and can be accepted with greater confidence than before because of the certainty of the fundamental physical basis.

Oscillographic Observations on Ultra-High-Frequency Sparks

EXPERIMENTS are in progress on the mechanism of the breakdown of gases at centimetre wavelengths, some of which have already been reported[1]. In the previous communication reference was made to the mid-gap streamers which, at atmospheric pressure, seem to constitute the birth-stage of a spark in a resonator energized at 2,800 megacycles per second. These streamers are regularly produced when a narrow beam of short-wave ultra-violet light, from a spark gap, is passed through the gas between the electrodes immediately before the 1·4-microsecond pulse reaches the resonator (Fig. 1). Photoelectrons in the gas itself execute oscillations of small amplitude in the electric field, and cause breakdown if the field is strong enough.

In extension of these experiments, apparatus has been set up to examine the variation of the oscillating field in the resonator during the period of a pulse producing breakdown. The output from a coupling loop, *L* (Fig. 1), is rectified and amplified and is then applied to the plates of a high-speed single-stroke oscillograph. Typical tracings for breakdowns in hydrogen, nitrogen and oxygen at atmospheric pressure are shown in Fig. 2.

The most remarkable feature of these oscillograms is the abruptness of the first stage of the breakdown, which in some gases takes only about one-thirtieth of a microsecond. In fact, the time of collapse of the field is comparable with those realized in gaps of the same order (1·4 cm.) when a unidirectional voltage causes the breakdown[2]. Furthermore, successive oscillograms taken in the same circumstances show a striking consistency, and suggest, in hydrogen at least, that the delay between attainment of the breakdown voltage and actual breakdown is very small: it appears that the rate of rise of voltage does not affect

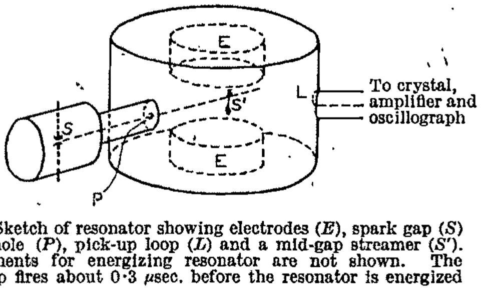

Fig. 1. Sketch of resonator showing electrodes (*E*), spark gap (*S*) and pinhole (*P*), pick-up loop (*L*) and a mid-gap streamer (*S'*). Arrangements for energizing resonator are not shown. The spark gap fires about 0·3 μsec. before the resonator is energized

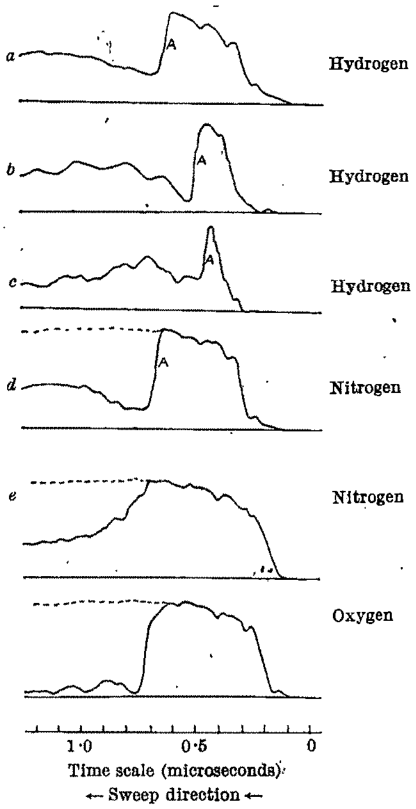

Fig. 2. Oscillograms showing collapse of field in resonator during breakdown: *a*, *b*, *c*, breakdown in hydrogen, pulse amplitude increasing from *a* to *c*, mid-gap irradiation; *d*, nitrogen, mid-gap irradiation; *e*, nitrogen, electrode irradiated through quartz; *f*, oxygen, mid-gap irradiation. Dotted lines show the unbroken pulse, obtained by cutting off irradiation (total duration, 1·4 µsec.). All observations at atmospheric pressure

the breakdown stress within the limits examined. Notwithstanding the presence of electrons in the gap, this absence of overshooting is surprising, since the measurements on ultra-high-frequency sparking potential show that the peak voltage at breakdown is less than the static breakdown voltage, usually by about 30 per cent. In such circumstances the coefficient of differential ionization, Townsend's α, should be small compared with the value in D.C. fields at breakdown; the amplitude of oscillation of the electrons should be 10^{-2} to 10^{-3} cm., and so a relatively slow development of a conducting filament might be expected, in sharp contrast with the observations.

When the initiating electrons are released at the electrode surface, using a spark outside the resonator and a quartz lens, the rate of collapse is slower (Fig. 2,*e*) and the discharge takes the form of a bright spot on the electrode surface, with a luminous tail. No difference has been observed in the breakdown stress as compared with that required to start the discharge in mid-gap.

The rate of collapse of the field in the first stage (Fig. 2,*a*) indicates that energy is being dissipated more rapidly than it is being supplied to the resonator, so that this first stage is associated with the discharge of the energy stored by resonance. The subsequent step in the oscillogram—an actual recovery in some cases—resembles the step observed in D.C. sparks by Rogowski and others[3,4].

We again wish to thank the Council of the Durham Colleges for granting one of us (W. A. P.) a sabbatical year, the British Electrical and Allied Industries Research Association for a grant towards the cost of the research, and the Director of the Armaments Research Establishment for the loan of the oscillograph.

Alien Plant Introductions on the Isle of Rhum

A NUMBER of very rare and interesting plants have been reported in recent years from the Isle of Rhum in the Inner Hebrides. Though Lady Bullough, the owner of the island, generously gave me permission to camp there for longer, I was unfortunately unable to spend more than three days on Rhum, and my knowledge of its flora is therefore very fragmentary. But thanks to the kindness of Prof. J. W. Heslop Harrison, who was staying on the island at the same time, I was enabled to see some at least of its most interesting plants. Of these I shall be especially concerned in this note with two only, namely, *Polycarpon tetraphyllum* (L.) L. and *Carex bicolor* All.

The first record of *Polycarpon tetraphyllum* in the Inner Hebrides ran as follows: "A single plant found growing in a rock crevice along the Kinloch Burn, Rhum; a new county record"[1]. On August 6, 1948, there were four plants in place of the original one. They were growing around the base of the outcrop of rock where the original plant had been detected. Two were large plants, bearing several rather upright stems; the other two were very small. One large and one small plant grew close together, and they were separated by a distance of some ten or twelve feet from the other two, which also grew together. From the middle of one of the two large plants, in such a way that the branches of the *Polycarpon* completely surrounded it, there sprouted a vigorous plant of *Juncus capitatus* Weig.; and there was also a small seedling that was probably of the same species. Such close juxtaposition of two exceedingly rare plants is most unexpected, even though a colony of some thirty plants of *Juncus capitatus* occurs about two hundred yards away. Beneath the other large plant of *Polycarpon* I found a very small flowering plant[2], which was eventually identified as a depauperate specimen of an alien annual *Wahlenbergia*, almost certainly *Wahlenbergia nutabunda* A.D.-C. This species seems to be unknown in Britain outside a few botanical gardens, where, however, as at Cambridge, it tends to maintain itself as a self-sown weed.

A single branch[2] of this second large plant of *Polycarpon* proved to be of a most unusual form. Its habit is strikingly different from that of the plant as it occurs in southern England, and indeed its combination of much-branched inflorescence and narrow acuminate sepals differentiates it from any of the specimens in the World Herbarium at the British Museum (Natural History). It is perhaps most nearly matched by specimens from Malta and Greece.

The above observations seem to leave little doubt that *Polycarpon tetraphyllum* is an alien introduction into Rhum.

Carex bicolor All. was first found in Britain on sparsely clad terraces above the easternmost tributary of the Allt Slugan à Choilich in the Coire Dubh, Isle of Rhum, at an elevation of between 1,250 and 1,500 feet[3]. Two separate colonies were recorded. A third colony, which I was enabled, by Prof. Heslop Harrison's directions, to see for myself, had been more recently discovered in a somewhat different locality, though still within the Coire Dubh. The following observations of this colony were made by Mr. T. R. M. Creighton and myself.

There were seven mature plants of the sedge, and also two young plants which were almost certainly of the same species. All were growing on almost bare gravel banks, at the junction of two small burns, at an altitude of about 940 ft. Two large plants were on the south bank of one of these burns, and the other seven on the north bank. Those on the north bank were fairly evenly spaced at intervals of about a foot, while the two on the south bank were several feet apart.

Of the seven mature plants one had specimens of both *Poa annua* L. and *Sagina apetala* Ard.[2] sprouting from among its leaves; two others had *Poa annua* growing in a similar way; and yet two others had *Sagina apetala*. These ruderal species, especially the *Sagina*, would scarcely be expected in such a locality. The neighbourhood, and particularly the rest of the extensive gravel banks, was thoroughly searched for further specimens of either. Though I cannot speak with complete confidence about the *Sagina* (since there was a large quantity of *Sagina procumbens* L. about, which might conceivably have camouflaged other small specimens of its congener), I fully satisfied myself that there were no other specimens of *Poa annua* in the neighbourhood.

No other arctic-alpine species accompanied the sedge; but there was, only 7 ft. from the nearest specimen of the sedge, a single small plant of *Juncus capitatus*.

The close association of annual ruderal species with *Carex bicolor*, its extreme rarity, its distribution, and the absence of arctic-alpine associates suggest that it too, like *Polycarpon tetraphyllum*, is an introduction into Rhum.

There are a few other plants recorded from the Isle of Rhum on which it is worth adding brief comments. *Viscaria alpina* (L.) Don[4] was seen growing on an unusually steep bank of rather bare stony soil at the foot of a small bluff. There are not more than a dozen plants in the whole colony, which covers an area of only a few square feet. No specimen is more than a single rosette, and even the strongest looks very weak in comparison with typical plants in Glen Clova. *Arenaria norvegica* Gunn.[1], on the other hand, is not only abundant over a relatively large area but also more vigorous than any specimens I have seen at Inchnadamph. Similarly, *Thlaspi calaminare* Lej. and Court[1], and at least two striking species of *Euphrasia*, are in considerable quantity, accompanied by an abundance of some very puzzling mossy saxifrages.

Parasitism of the Mealybug Vectors of Swollen-Shoot of Cacao

IN view of an increasing general interest in the research in progress on the mealybug vectors of swollen-shoot virus diseases of cacao in West Africa, it seems advisable to make known immediately certain factual data which are being prepared for publication in full.

The most important vector of swollen-shoot viruses, the mealybug *Pseudococcus njalensis* Laing, is naturally parasitized in the Gold Coast at a rate of about 3 per cent of the adults[1]. This rate varies considerably under the conditions prevailing in Gold Coast cacao farms, and has been shown to be consistently as low as 1·7 per cent, and consistently as high as 5·4 per cent in areas separated by only a few hundred yards. The mean rate over the past twenty months works out at 3·1 per cent for the Tafo district of the Eastern Province of the Gold Coast.

Investigations have shown that there are nine species of Encyrtid endoparasites and two species of Dipterous ectoparasites which attack *Ps. njalensis* in the Tafo district. There are statistically significant differences in the distribution of the parasite species, and in the degree of parasitism effected by a given species when its mealybug hosts are attended by different species of ants, most of which are referable to the genus *Crematogaster*.

Three of the nine Hymenopterous parasites have been determined by Mr. G. J. Kerrich, of the Commonwealth Institute of Entomology, as species of *Anagyrus*, and 73 per cent of the total adult parasites reared from mealybugs collected in the field are referable to this genus. It is of particular interest that, even when the natural parasite incidence is low, *Anagyrus pullus* Compere is still the dominant species. The two Dipterous species together account for approximately 0·4 per cent of the total parasitism, and are thus of negligible importance.

While visiting Kenya in August of the present year, one of us (A. F. P.) discussed the biological control of the coffee mealybug (*Ps. kenyæ* Le Pelley) with Dr. R. H. Le Pelley, and as a result decided to take back to the Gold Coast an efficient *Anagyrus* parasite of this species for trial on *Ps. njalensis*. Through the kindness of Dr. Le Pelley, mealybugs parasitized by a biological race of *Anagyrus kivuensis* Compere[2] were brought back to Tafo in gelatine capsules. After emergence the parasites were compared with previously determined specimens as a precaution against hyper-parasites, and males and females, usually in the proportion of 1 : 3, were transferred to 6 in. by 1 in. specimen tubes. Adults of *Ps. njalensis* were subjected to the parasites in the tubes for about twenty-four hours, and were then transferred to feed on the cotyledons of cacao beans. Afterwards, it was found to be unnecessary to feed adult mealybugs after parasitization; they were transferred to 250 ml. conical flasks, from which the transference of adult parasites was effected by fixing a specimen tube over the mouth with 'Plasticene' and darkening the flask.

This biological race of *Anagyrus kivuensis*, originally introduced into Kenya from Uganda by A. R. Melville, has now been reared through four generations on *Ps. njalensis*, and has also been reared successfully on *Ps. citri* (Risso), and on *Ps. brevipes* (Ckll.).

The discovery that one parasite of *Ps. kenyæ* will attack *Ps. njalensis* indicates that other parasites used to suppress *Ps. kenyæ* on coffee in Kenya might also be used against West African cacao mealybugs, and investigations are proceeding with this in mind.

Life-history of *Bonnemaisonia hamifera* (*Trailliella intricata*)

J. Feldmann and G. Feldmann[1], when cultivating carpospores of *Bonnemaisonia asparagoides*, succeeded in getting *Hymenoclonium serpens* as the tetrasporophyte. The validity of these results, however, was challenged by Kylin[2], who supposed that the formations held to be tetraspores by the Feldmanns are in reality only end-cells which have started to divide by oblique walls typical of the adult axis. What, according to the Feldmanns, seems to be a tetrasporophyte is only a branched protonema of the gametophyte. Thus, in Kylin's opinion, there are only two phases in the life-history, the gametophyte and the carposporophyte (quoted by Drew[3]).

The problem seems to be settled by investigations we have carried out with another species of *Bonnemaisonia*. In their natural habitats *Bonnemaisonia hamifera* and *Trailliella intricata* are frequently found together. Therefore the Feldmanns supposed that *Trailliella* might be a potential part of the life-cycle of *Bonnemaisonia hamifera*. We accordingly undertook to cultivate *Trailliella intricata*. It formed reproductive organs in late autumn which are, without doubt, tetraspores (Fig. 1). Kylin's criticism certainly does not apply in this case. The spores germinating in culture developed into plants of *Bonnemaisonia hamifera* which we succeeded in cultivating until the formation of cystocarps (Fig. 2). It follows that *Trailliella intricata* is the tetrasporophyte of *Bonnemaisonia hamifera*. In order to complete the picture, it will seem to be necessary to cultivate specimens of *Trailliella* out of the carpospores of *Bonnemaisonia hamifera*. This is impossible, since no antheridia have been found in *Bonnemaisonia hamifera*[1] except in Japan. Accordingly, only in that region can carpospores be found.

As the material from which our cultures were grown was of European origin (Heligoland), we found only female plants. The very phase, however, which is lacking in our cultures is represented by the cultures of the Feldmanns. Thus the life-history of the Bonnemaisoniaceæ might be regarded as being clarified so far as the external development is concerned (diplobiontic type). Our present task, not yet finished, is to ascertain the place of meiosis. In *Bonnemaisonia asparagoides*, Svedelius[4] has found it to be directly after fertilization; we suppose that it will be in the same place in *Bonnemaisonia hamifera*.

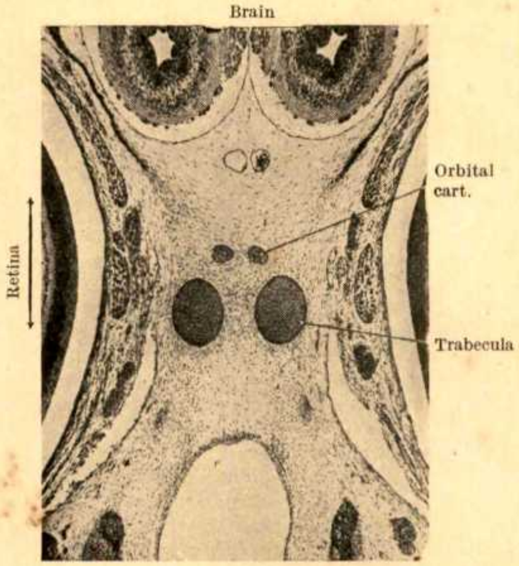
Orbital Cartilages in Snakes

IN adult snakes the trabeculæ are the only elements of the chondrocranium which are present in the orbital region. They remain paired behind the level of the nasal capsule so that the chondrocranium is platytrabic.

Parker[1], working with hand-cut sections, described and figured a pair of small unfused orbitosphenoids above the trabeculæ in the mid-orbital region of an embryo of *Tropidonotus* (*Natrix*) *natrix*. Subsequent investigators have searched in vain for these structures in embryos of several species of snakes (see de Beer[2]), and Parker's interpretation has been regarded as incorrect (Brock[3]).

During an investigation of the anterior brain-case of Sauropsida a number of embryos of different species of snakes have been examined. A 7·2-mm. head-length embryo of *Vipera berus* clearly shows two small nodules of cartilage above the trabeculæ in the



Vipera berus, 7·2-mm. head-length embryo. Transverse section through head at mid-orbital level, showing rudimentary orbital cartilages above the trabeculæ (Masson's trichrome stain, × 43)

mid-orbital region (see reproduction). The position of these nodules is similar to that of the orbitosphenoids figured by Parker in *Natrix*, and they are not connected with each other or with any other structure. The nodule on the right side has a longitudinal extent of 250 μ, and that on the left an extent of 160 μ. These structures were not found in earlier or later embryonic stages of *Vipera*, and it is concluded that they are only present for a brief period during the life of the embryo.

Only in a single instance was any comparable structure found among a large collection of other snake embryos. In a 12-mm. head-length embryo of *Python molurus*, a small nodule of cartilage was present in the midline above the trabeculæ at mid-orbital level.

Although made on different species, these observations provide some confirmation of Parker's account. It seems very probable that the structures described do, in fact, represent rudiments of the saurian orbital cartilages, and that the more extensive endocranial side-walls of lizards have some parallel in the ophidian embryo.

Black Rust in South-East Scotland

THE last few seasons have been notable for attacks of black or stem rust (*Puccinia graminis*) on cereals in the south-east of Scotland. The rust was particularly widespread and severe in 1947. It is possible that the rainfall and humidity of the spring and early summer being more than average, followed by a long hot period until harvest, created ideal conditions for the development and spread of the rust.

On looking into the reasons for these attacks, it soon became obvious that the common barberry (the alternate host of the rust) is frequently found in hedges, the bushes being especially numerous in the Border districts. Wheat and barley are seldom attacked to any extent; but oats are often seriously affected in the immediate neighbourhood of barberries. The straw becomes brittle and lodges rather easily, and the ears do not fill properly.

Many of the grasses are also heavily infected. In 1948 the rust was found on *Poa trivialis* and *P. pratensis*. So far as I know, this is the first record of *Puccinia graminis poæ* in Britain. Both species were growing near infected barberry bushes.

The serious losses caused by this rust in the vicinity of barberries suggest that a barberry eradication campaign in the south-east of Scotland would be most beneficial. If this could be encouraged, the losses brought about by black rust would be greatly diminished.

White-eyed Mutants in *Calliphora erythrocephala*, Meig.

SOME months ago, Dr. P. Tate[1] gave a review of white-eyed mutants of Diptera. In his paper Tate stated that in *Calliphora erythrocephala* the male never manifests the white-eyed character.

Some years ago a white-eyed mutant of *Calliphora erythrocephala* appeared in our mass cultures, and in this case both white-eyed females and males occurred. We reared the mutant and obtained a mass culture of it. At that time, however, we were busy with other work, and so we did not investigate the mutant as to the mode of inheritance. Unfortunately, after some time the culture was allowed to die out.

It is evident that the mutation found in our culture differs from that of Tate, his mutation being sex-limited, which was not the case with ours. It is interesting to note that the same visible character may be due to different gene mutations.

TEMPERATURE CHANGES IN HIBERNATING HEDGEHOGS

By ELSIE PROCTOR
Bedford Froebel Training College

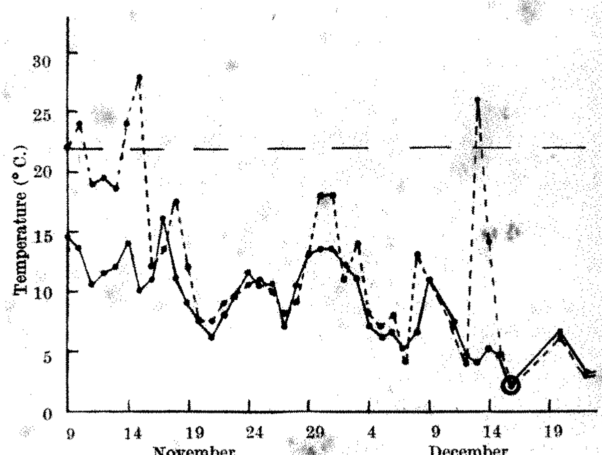
THESE records of the varying temperatures of hedgehogs during their period of hibernation, and of the relationship between these and relevant air temperatures, were made during three winters before and just after the Second World War. In pre-war days the feeding of these animals was less difficult (we used milk and eggs). Our aims were to discover: (1) whether an adequate supply of fresh food would delay hibernation; and (2) to what degree temperature changes were related to or independent of relevant air temperatures.

We have long lists of statistics covering three or four years of observation; but the integration of our results gives some fairly definite information, and a frequent recurrence and constancy of certain temperatures which seem even more significant now, in view of the fact that we are receiving some of the same recurring constants with other hibernating mammals—in particular with *Glis glis*, one of Dr. Vever's squirrel-tailed dormice.

The hedgehog, when not hibernating, is a normally homoiothermic animal with a constant summer temperature a little higher than our own (37·0° C. or 98·6° F.). During its hibernation it passes through a poikilothermic phase, that is, it becomes virtually a 'cold-blooded' animal, with a temperature which varies with that of the surrounding atmosphere. The length of this poikilothermic phase may be lengthened, as in the case of our H.3, which had not achieved its normal summer temperature by midsummer (in captivity).

Outlined below are some of our more important discoveries concerning hedgehogs 1, 2 and 3, with a graph of the temperature behaviour of H.3—which showed a remarkable recovery from the abnormally low temperature of 2·0° C.

Hedgehog 1 (*Female*). H.1 was received into a hutch in an old outside aviary on January 18, 1937. It was already in hibernation, and its temperature was 11·0° C.—that of the air in the aviary was 15·0° C. Between January 18 and March 12, 1937, we kept daily records (at 1 p.m.) of the temperatures of hedgehog and of air.



Full line, air temperature; broken line, hedgehog's temperature. — — —, line of W.T.22, waking temperature. ⊙, occasion upon which H.3 sustained a temperature of 2·0° C.

Four times during this period the hedgehog woke from hibernation, with no external stimulus except that of varying air temperature. The 'waking temperature' was found each time to be 22·0° C. (71·6° F.), and this temperature was obtained on all but one occasion only after the air temperature had risen to 12·0° C. (53·6° F.). It was observed that whenever the air temperature was recorded at 12·0° C. the animal stirred and that when its own temperature touched 22·0° C. it sought food (which was always accessible). The hedgehog is by no means a continuously 'deep sleeper' in hibernation. Even at its lowest ebb (except on the classic occasion when H.3 touched 2·0° C.) it showed slight movements of the spines in response to touch. This aggressive stiffening of the spines was our most reliable indication of life even when heart beats and breathing were imperceptible.

The blood temperature of H.1 never rose to the normal summer temperature of 37·0° C. while in captivity. At the end of March we took it back to the woods. Whether its temperature ever became normal in a wild environment we do not know, although another hedgehog (H.4) captured in July 1941 and brought in for two days observation gave us the normal summer temperature of 37·0° C., or 98·6° F. We formed the impression that hedgehogs retained in captivity during their hibernating period and afterwards do not achieve a normal summer temperature. This hypothesis was borne out by H.3, which on June 11 still remained at 32·0° C. (89·6° F.).

Hedgehog 2 (*Male*). (The winter of 1938.) The brief record of temperature readings from our second hedgehog was important from one aspect only, that the animal died and we were able to record a 'death temperature'. This was a smaller animal than H.1 and not so well nourished. We found it in deep hibernation in February and knew that it was alive from slow but perceptible heart-beats and the sensitivity to touch of the spines. On February 26 all spine reaction ceased, and at 4·0° C. the hedgehog died, and in death relaxed from a 'rolled' to a straight position. We waited for putrefaction to set in before disposing of the body. This case was amply justified when H.3 (1939–40) sank below this death temperature and revived again.

In order to facilitate references to our records we now established a series of abbreviations for the more outstanding or constant of our temperature results, as follows:

W.T.22 = waking temperature of hedgehog (constant); that is, 22·0° C. (71·6° F.).

C.T.37 = normal summer temperature (constant); that is, 37·0° C. (98·6° F.).

S.N.T.32 = subnormal summer temperature in captivity (constant); that is, 32·0° C. (89·6° F.).

D.T.4 = death temperature of H.2; that is, 4·0° C. (39·2° F.).

Hedgehog 3 (*Female*) (1939–40). Hedgehog 3, from which we obtained our most significant range of temperature variations, was a well-nourished female. We found her in a local ditch on November 9, awake but not very active. It is interesting to note at this point that the female hedgehogs (probably because of extra subcutaneous fat) appear to be better nourished and to survive winter better than do the males.

Between November 9, 1939, and the final emergence from hibernation on April 21, 1940, H.3's blood temperature rose above W.T.22 four times; but with these exceptions a state of hibernation was maintained for five months.

We retained H.3 in captivity until June 11, in an effort to record the constant summer temperature, but C.T.37 was never achieved by H.3. After April 21 until we let her go on June 11 she remained healthy, and nocturnally active, with a constant temperature of 32·0° C. (S.N.T.32).

The most startling performance of H.3 was her amazing recovery after having sustained the low temperature of 2·0° C.—two degrees lower than the death temperature of H.2. The winter of 1939 was severe, a particularly bitter December. Apart from one rise of air temperature between December 1 and 16, which dragged up the blood temperature of H.3 with it, the atmosphere became progressively colder until we recorded 2·0° C. as the temperature of both air and hedgehog on December 16.

The revival of H.3. No readings were taken between December 23 and March 1, because H.3 was presumed dead. Even spine reaction had ceased although the animal remained curled up. A student examining the hutches on March 1 stated that she believed the hedgehog to be alive, although there seemed nothing to justify this belief at the time. However, we began temperature records again, only to find that air and blood temperatures were practically similar. Since this was fairly common during deep hibernation we persisted, and at the beginning of April a slight reaction of spines was observed, and we knew H.3 to be alive. The blood temperature remained 'chained' to the air temperature until a general rise took place on April 19, 20 and 21, during which time the blood temperature of H.3 gained independence and eventually rose to 32·0° C. (S.N.T.32), where it remained constant until the release of the animal on June 11. As stated before, it never achieved a normal summer temperature in captivity.

Two other hedgehogs, H.4 (which has already been mentioned) and H.5, were studied in subsequent years. Their records helped to verify our previous discoveries.

D.D.T. AND 'GAMMEXANE' AS RESIDUAL INSECTICIDES AGAINST *ANOPHELES GAMBIÆ* IN AFRICAN HOUSES

By Dr. R. C. MUIRHEAD-THOMSON
Medical Laboratory, Dar-es-Salaam, Tanganyika

DESPITE the great developments in residual insecticides in the last few years, there is still difficulty in assessing and comparing their value in controlling anopheles—under African conditions at least.

The dramatic fall in the day-catch of mosquitoes in houses treated with D.D.T. is now known to be of doubtful significance by itself, and may give an entirely misleading impression that a high kill of mosquitoes has been obtained[1].

To estimate the effect on the incidence of malaria, or rather on the incidence of new infections, of large-scale treatment of African houses, is also a difficult matter, although in theory this should constitute the ultimate criterion of success. Large-scale experiments of this kind have to be planned on a long-term basis, during which time the African may be exposed several times to infection outside the controlled area. This may introduce a considerable source of error and uncertainty into the experiment, a point which has recently been emphasized by Walton[2].

It seems to me that before embarking on such large-scale experiments, the first thing is to try to find out exactly what happens inside an African house after treatment with a residual insecticide. For this purpose the technique worked out in West Africa offers the most simple and accurate solution so far[1,3].

In a study of the normal habits of anopheles in African native houses, it was found that mosquitoes leaving the shelter of the house at dusk or dawn were strongly attracted to light coming in through window and door openings. To the restless mosquito the attraction to light was equally strong during the hours of darkness, mosquitoes being attracted to the faint light coming in from the night sky. This principle was used to design a simple mud and thatch African-type hut in which two to four paid Africans slept every night. The hut was so constructed that while hungry anopheles could gain entrance through innumerable small cracks and crevices, the only light coming in from outside was through a 1-ft. square window opening, over which a mosquito netting trap-cage was fixed. Mosquitoes attracted to the light were directed into a narrowing funnel which led through a small opening into the cage. This one-way valve idea is essential, as mosquitoes trapped in the cage are attracted once more towards the darkness of the hut when bright daylight appears.

D.D.T.

D.D.T. in kerosene. As already reported[1], huts of this type were used in Lagos, West Africa, to test the effect of house treatment with D.D.T. in kerosene. Treatment of inside walls and roof at the rate of approximately 100 and 250 mgm. D.D.T. per sq. ft. afforded almost complete protection from biting for about one week. After that time, a steadily increasing number of blood-fed *A. gambiæ* and *A. melas* were taken every day in the window-traps. Among these anopheles there was no appreciable mortality in the following 48 hours. Within a few weeks of treatment, large numbers of anopheles were feeding regularly in the treated huts, were irritated by brief contact with the treated walls and roof, and were trapped in the window-cage as they attempted to leave the hut. The day-time catch of resting anopheles inside the treated hut remained practically zero for at least two months after treatment. The initial few days of complete freedom from biting was later shown to be due to the repellent effect of the heavy dose of kerosene which accompanied the D.D.T.

Possibly the first suggestion that mosquito control by treatment of houses with D.D.T. might not be as simple as it first appeared was due to Kennedy[4], who showed in laboratory experiments with *Anopheles maculipennis* that mosquitoes are excited by contact with D.D.T.-treated surfaces. In this state they were attracted to light, and could escape without having absorbed a lethal dose of the insecticide.

The field experiments in Lagos show that this irritant effect of D.D.T.-treated surfaces is a factor of such importance as to throw doubts on the value of house treatment with D.D.T. as a control measure against *A. gambiæ*.

D.D.T. dispersible powder. Recently in Dar-es-Salaam, Tanganyika, these experiments have been repeated using D.D.T. dispersible powder (1 lb. to 1 gallon of water). One particularly suitable hut was treated at the rate of approximately 400 mgm. of the powder per sq. ft. Here there was no initial period of complete protection. *A. gambiæ* were found to be feeding in the hut in numbers on the night after treatment, and from then onwards large numbers of blood-fed mosquitoes were taken in the window-trap every day. Among these there was no appreciable mortality in the following 24 hours, and a variable mortality never exceeding 20 per cent in the following 48 hours. Inside the treated hut the number of dead anopheles taken on the floor sheet was only a fraction of those escaping unharmed. For at least two months after treatment not a single resting anopheles was found inside the hut, creating the familiar illusion that a high kill of mosquitoes had been obtained.

It is possible that in some parts of the world the mere fact of driving the mosquitoes from the shelter of the house to an uncertain fate out-of-doors might achieve useful results; but in the coastal regions of East and West Africa, *A. gambiæ* normally make part-time use of outdoor resting places. As there is no scarcity of such shelters, it is unlikely that the mosquitoes are seriously affected by having to take to the open air.

Attempts were made to overcome this serious irritant property of D.D.T., such as by screening the window opening with transparent cloth treated with D.D.T., in the hope that irritated mosquitoes attracted to the light would have additional contact with the insecticide. These have not proved very encouraging, although it is still possible that the mosquito mortality might be influenced by the type of house. However, in view of the excellent results obtained with 'Gammexane' dispersible powder described below, it is doubtful if it is worth while trying to overcome these serious defects of D.D.T.

'Gammexane' Dispersible Powder

In Dar-es-Salaam, huts of the type described above have been used to test the residual insecticidal value of 'Gammexane' dispersible powder, *P.* 530. The inner walls and ceiling of a particularly suitable hut were sprayed with half a gallon of a mixture of 1 lb. powder to 1 gallon water. This worked out at approximately 400 mgm. powder, or 24 mgm. gamma isomer, per sq. ft. As with the D.D.T. experiments, not a single living anopheles was found resting in the hut for weeks after treatment; but in striking contrast to D.D.T., not a single living anopheles was taken in the window-trap up to thirteen weeks after treatment, by which time the falling mosquito population put an end to the experiment. During all that time numbers of dead *A. gambiæ* were taken on the floor sheet at every collection. Feeding still takes place inside the treated hut; but a high proportion of *A. gambiæ* are evidently killed before they can bite, especially in the first two or three weeks after treatment. Among those that feed in the hut, there is no indication of that irritation that drives them out of D.D.T.-treated houses. The window-trap catch remained very low throughout the experiment, and all anopheles found there were already dead. The continued steady figure for dead anopheles found on the floor sheet is proof of continued lethal action for at least three months after treatment.

These results are very encouraging. In persistence and killing power, this particular form of 'Gammexane' seems to satisfy the most critical requirements, and its insecticidal powers are clearly superior to those of D.D.T. Even allowing for the fact that in these huts the insecticide is being tested under ideal conditions, in which every possible resting-place for mosquitoes is heavily treated, it appears as if we now have an insecticide of real value in the control of *A. gambiæ* at least.

The success of these hut experiments is dependent on a high population of anopheles mosquitoes maintained over several months. This is an ideal not always easy to attain in the field. But when conditions are favourable it should be possible to get accurate comparisons between different dosages or different insecticides in a matter of months rather than years. The design of the hut could be modified to conform to local housing conditions without altering the main principle of the attraction to the window-trap; and it is felt that these experiments might be repeated with advantage in other countries besides Africa.

WEST AFRICAN CACAO RESEARCH INSTITUTE

A COMPREHENSIVE account of the work of this Institute, situated at Tafo, Gold Coast, is available in the annual reports for 1946 and 1947 (Crown Agents, 4 Millbank, London, S.W.1. 5*s*.). The programme of research now being organised and undertaken includes the establishment of type collections of different varieties of *Theobroma cacao* and related species, selection and hybridization investigations, comprehensive studies of growth and cultivation, and, in particular, the study of the complex of virus diseases known as swollen-shoot, and of capsid pests, with the view of formulating measures of control.

Notwithstanding the many difficulties which have been encountered, it is evident from these reports that considerable progress is being made on a wide front and that many new facts, of great scientific interest as well as of practical importance, are being ascertained. In the matter of swollen-shoot disease, a considerable number of virus strains have now been recorded in the Ivory Coast, Gold Coast and Nigerian cacao belt, each locality showing some particularity of symptoms in the host plant. The disease has now been observed on all the main soils on which the crop is grown in West Africa. Several distinct viruses are involved, some of these not producing the characteristic stem swellings. Much useful information regarding the insect vectors is now available, and techniques have been devised so that transmission experiments can be carried out on a considerable scale. While no cacao tree immune to virus has yet been discovered, varying degrees of tolerance have been shown to occur. The virus is not transmitted by seed. That swollen-shoot disease can be controlled by cutting out infected trees has been proved; and provided the soil is suitable, cacao can be successfully re-established on areas previously devastated by the disease.

Capsids of four genera attacking cacao in West Africa are being given close attention, and their life-history, mode of nutrition, population fluctuation, and destructive effects studied. It appears from comprehensive studies that the several capsids are in the course of changing from their indigenous host plants to cacao. Spraying of young trees with nicotine sulphate has given good protection, but the method is not economic.

Soil surveys so far undertaken have shown that the incidence of virus disease or capsid pests is apparently not dependent on soil type. A preliminary general soil survey of the Gold Coast, Togo, Nigeria, and the British Cameroons has been completed, and the principal soils identified and their distribution roughly estimated. Further detailed surveys are in progress and much valuable information along several lines is being accumulated.

The reports also give accounts of the work on experimental plots in native farms, and of relevant botanical, horticultural, mycological and physiological studies.

The Director and his staff are to be congratulated on their judiciously balanced programme of fundamental and applied research, and on the progress which they have been able to report on so many interesting lines of work.

DUST AND HEALTH

SECTION V of the Conference on "Dust in Industry" arranged at Leeds by the Society of Chemical Industry met on September 30, under the chairmanship of Prof. E. C. Dodds, in the main lecture theatre of the Chemical Department of the University.

The large attendance at this section indicated the keenness of the audience for this particular branch of health hazards, although good attendance was the rule throughout all the sections.

Unfortunately Prof. R. R. Fabre, dean of the Faculty of Pharmacy in the University of Paris, was unable to be present to read his paper on "Pulmonary Penetration by Toxic Products of Industry"; but the other five communications were presented and were discussed at some length.

The first paper, by Prof. W. M. Cumming and Dr. I. A. Brownlie, was called "Tetryl Dermatitis and its Prevention". Prof. Cumming gave a review of the problem of tetryl dermatitis, which at one period proved a very serious obstacle to munition production during the War. As was pointed out, tetryl is profoundly altered in constitution by exposure to ultra-violet light, and it is only on the exposed area of the skin that the dermatitis appears. He therefore developed the interesting theory that the dermatitis was produced by the products of ultra-violet radiation actually produced over the areas of skin exposed to sunlight. He also demonstrated that these products of irradiation could combine with proteins, and it might well be that these protein complexes produced immunity reactions which were responsible for the actual dermatitis. The paper presented an ingenious attempt to bring real experimental method into the study of this very difficult subject, and the consensus of opinion at the end of the discussion was that Prof. Cumming had certainly indicated a valuable new line of approach.

This was followed by a brief paper on the subject of barrier creams. In this it was pointed out that the constituents of a barrier should be very carefully studied to see whether the particular toxic agent against which they are to form a barrier is soluble in them. The lecturer pointed out that in a number of barrier creams the constituents were actually good solvents for the toxic agents, and therefore actually assisted the penetration rather than inhibited it.

Prof. E. J. King gave a masterly summary of the present position of the study and treatment of silicosis. He described in detail the modern treatment, consisting of inhalation of aluminium powder. This again provoked an interesting discussion as to the possible danger of aluminium itself as a toxic agent.

A paper by Dr. T. A. Lloyd-Davies described the high incidence of pulmonary infections in permanganate plants. Dr. Lloyd-Davies provided evidence which supported the view that the lesion, a pneumonitis, is caused by manganese inhalation.

A very interesting review of the arsenical dusts in industry, prepared by Dr. A. N. Currie, but presented by Dr. Buchanan, showed that, despite its sinister reputation, arsenic is not responsible for frequent damage to health in industry. The question of arsenic as a cause of cutaneous cancer was carefully reviewed and discussed.

The final paper in this session was one by Prof. A. L. Roberts, on a method for determining free silica in dusts. This is a very elaborate technique for the determination of particulate crystalline silica.

The interest in industrial medicine in Great Britain was clearly demonstrated by the large attendance at this meeting, and by the really high quality of the discussion which took place at the end. It was interesting to note the complete fusion of interests of the medical workers, experimental biological workers and the actual chemists, engineers and mining engineers who operate the industries in question. There can be no doubt that the Society of Chemical Industry performed a very useful function in arranging this Conference, and it was the unanimous wish that others on the same lines should be arranged.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, January 17

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. Francis Huxley: "The Oxford Expedition to Gambia Colony".

Tuesday, January 18

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. Kathleen Lonsdale, F.R.S.: "Art and Architecture in Science".*

Royal Society of Arts, Dominions and Colonies Section (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. W. E. F. Ward: "Mass Education in the Colonies".

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.15 p.m.—Dr. E. Ashworth Underwood: "The Development of Modern Physiology, 1700–1900".* (Further Lectures on January 25, February 1 and February 8.)

Institution of Electrical Engineers, Radio Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Should British Universities consider the Establishment of Special Degrees in Radio?" (to be opened by Prof. E. B. Moullin).

Conway Discussion Circle (in the Library, Conway Hall, Red Lion Square, London, W.C.1), at 7 p.m.—Mr. Hector Hawton: "Discussion on Marxism and Intellectual Freedom".*

Society of Chemical Industry, Fine Chemicals Group (in the large Anatomy Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Discussion on "The Approach to the Chemotherapy of Tuberculosis" (to be opened by Dr. James Walker and Dr. P. M. D'Arcy Hart).

Textile Institute, Yorkshire Section (at the Midland Bank, Bradford), at 7 p.m.—Mr. Stansfield Haigh: "Hairs—their Properties and Uses".

Wednesday, January 19

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Royal Statistical Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. H. Campion: "International Statistics".

Manchester Metallurgical Society (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Mr. J. I. Morley: "Metallography of Stainless and Heat Resisting Steels".

Royal Institute of Chemistry, London and S.E. Counties Section (at the Royal Society of Medicine, 1 Wimpole Street, London, W.1), at 6.30 p.m.—Prof. W. Wardlaw: "The Ministry of Labour and the Profession of Chemistry".

Society of Chemical Industry, Plastics Group (joint meeting with the **London Section**, at the Royal Institution, Albemarle Street, London, W.1), at 6.30 p.m.—Mr. H. V. Potter: "Synthetic Fibres—Historical Survey of the Development of some Synthetic Fibrous Materials" (Jubilee Memorial Lecture).

Thursday, January 20

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. L. J. Mordell, F.R.S.: "Rational Points on Cubic Surfaces".

Institution of Electrical Engineers, Measurements Section (joint meeting with the **Radio** and **Utilization Sections**, at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. A. Langley Morris: "Small Power Transformers for Aircraft Electrical Equipments".

Royal Photographic Society, Scientific and Technical Group (at 16 Princes Gate, London, S.W.7), at 7 p.m.—Dr. A. Hughes: "The Kinephotomicrography of the Living Cell".

Chemical Society (at the Royal Institution, Albemarle Street, London, W.1), at 7.15 p.m.—Prof. F. E. King: "Three- and Four-membered Heterocyclic Rings" (Tilden Lecture). (To be repeated on Friday, January 28, at 5 p.m., in the Chemistry Department, King's College, Newcastle-upon-Tyne.)

Chemical Society, Northern Ireland Section (joint meeting with the **Local Sections** of the **Royal Institute of Chemistry** and the **Society of Chemical Industry**, in the Lecture Theatre, Department of Agricultural Chemistry, Queen's University, Belfast), at 7.30 p.m.—Sir Jack Drummond, F.R.S.: "Nutritional Theories reviewed in the Light of War-time Experience".

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. H. C. Trowell: "A Critical Review of Malignant Malnutrition (Kwashiorkor)".

Textile Institute, Irish (Belfast) Section (at the College of Technology, Belfast), at 7.30 p.m.—Mr. G. Shaw: "Textile Testing Methods and Problems".

Friday, January 21

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Engineer Vice-Admiral Sir John Kingcome, K.C.B.: "Marine Engineering in the Royal Navy" (Thomas Lowe Gray Lecture).

Society of Dyers and Colourists, Manchester Section (at the Gas Department Showrooms, Manchester), at 6.30 p.m.—Dr. T. Vickerstaff: "A Study of the Factors Controlling Dyeing Behaviour".

Institution of the Rubber Industry, Manchester and District Section (joint meeting with the **Plastics Institute**, at the Engineers' Club, Albert Square, Manchester), at 6.45 p.m.—Dr. J. R. Hetherington: "Applications of Acrylic and Vinyl Pastes".

Institute of Physics, Manchester and District Branch (in the New Physics Theatre, The University, Manchester), at 7 p.m.—Dr. T. Bedford: "Environmental Warmth in relation to Human Comfort".

Society of Instrument Technology, Midland Section (at the Arden Hotel, New Street, Birmingham), at 7 p.m.—Mr. A. J. Young: "Impressions of Recent American Instrumentation".

Society of Chemical Industry, Food Group (joint meeting with the **Glasgow Section**, at the Royal Technical College, Glasgow), at 7.15 p.m.—Dr. J. B. M. Coppock: "Some Aspects of Bakery Research".

Society of Glass Technology, North-West Section (at the Gas Showrooms, Radiant House, St. Helens), at 7.15 p.m.—Mr. S. T. Pickering: "Optical Glass".

Saturday, January 22

Biochemical Society (at the British Postgraduate Medical School, Ducane Road, London, W.12), at 11 a.m.—Scientific Papers.

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Mathematical Assistant in the Electro-Technical Research Section at Headquarters in London—The Director of Establishments, British Electricity Authority, British Electricity House, Great Portland Street, London, W.1 (January 19).

Lecturer in Chemistry at the Blackburn Municipal Technical College and School of Art—The Director of Education, Education Offices, Library Street, Blackburn (January 22).

Senior Lecturer in Physiology—The Dean of the Medical College, St. Bartholomew's Hospital, West Smithfield, London, E.C.1 (January 22).

Superintending Geologists (2) for the Geological Survey of Pakistan, under the Ministry of Education and Industries, Government of Pakistan—The Office of the High Commissioner for Pakistan, 14 Fitzhardinge Street, London, W.1 (January 25).

Senior Lecturer in the Department of Civil Engineering, University of Capetown—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (January 28).

Willow Officer at Long Ashton Research Station—The Secretary and Registrar, The University, Bristol 8 (January 29).

Senior Member of the Staff, and a **Lecturer** (Grade III), **in the Department of Physiology**—The Registrar, The University, Liverpool (January 29).

Senior Lecturer in Civil Engineering, Natal University College, Durban—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (January 30).

Senior Assistant in Physics—The Director of Education, The Polytechnic, 309 Regent Street, London, W.1 (January 31).

Research Botanist in the Department of Allergic Disorders—The Secretary, Wright-Fleming Institute of Microbiology, St. Mary's Hospital, Paddington, London, W.2 (January 31).

Senior Research Officer (Fibre Physicist), in the C.S.I.R. Wool Textile Laboratory, Geelong, Victoria—The Chief Scientific Liaison Officer, Commonwealth of Australia, Africa House, Kingsway, London, W.C.2, quoting No. 2063 (February 5).

Works Manager (optical), scientific and precision instruments manufacture, Ordnance Factory, Dehra Dun, Indian Ordnance Service—The High Commissioner for India, General Department, India House, Aldwych, London, W.C.2, quoting 58.L (February 7).

Readership in Mathematics at King's College—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 10).

Chemist or Bio-chemist at the Plant Chemistry Laboratory, Palmerston North—The Office of the High Commissioner for New Zealand, 415 Strand, London, W.C.2 (February 15).

Professor of Applied Physical Chemistry, and a **Professor of Inorganic Technology**, in the Institute of Chemical Technology, Farouk I University—The Egyptian Education Bureau, 4 Chesterfield Gardens, London, W.1 (February 15).

Assistant Professional Officer (physicist) at the Union Observatory, Johannesburg—The Secretary, Union of South Africa, South Africa House, Trafalgar Square, London, W.C.2 (February 19).

Chair of Educational Psychology at the Institute of Education—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 24).

Chair of Biochemistry in the University of Sydney—The Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (Sydney, February 28).

Chair of Philosophy—The Registrar, The University, Sheffield (March 1).

I.C.I. Research Fellowships for research in biochemistry, chemistry, engineering, pharmacology or physics—The Secretary, The University, Edinburgh (March 15).

Director of the Institute of Social and Economic Research, University College, Ibadan, Nigeria—The Under-Secretary of State, Research Department, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (March 31).

Turner and Newall Research Fellowships for research in engineering, inorganic chemistry, physics and allied subjects—The Registrar, The University, Manchester 13 (April 30).

I.C.I. Research Fellowships for research in chemistry, physics and allied subjects—The Registrar, The University, Manchester 13 (April 30).

Statistician with experience of 'operational research' for work on strength of packages, and a **Graduate Chemist** for work on emulsification problems in lithographic printing—The Printing, Packaging and Allied Trades Research Association, Randal Road, Leatherhead, Surrey.

Lecturer in Biology—The Principal, Derby Technical College, Normanton Road, Derby.

Biochemists (2) with research experience, for work on the separation and characterization of large molecules of biological origin—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Research Chemist—Dr. A. B. P. Page, Imperial College Field Station, Silwood Park, Sunninghill, Berks.

Research Assistant to work on horticultural problems, especially those relating to glasshouses and glasshouse crops—The Curator, John Innes Horticultural Institution, 31 Mostyn Road, London, S.W.19.

Young Chemist, for research in microbiology—The Secretary, Wright-Fleming Institute of Microbiology, St. Mary's Hospital, Paddington, London, W.2.

Electrical Engineers in the Electrical Department, Gold Coast Colony—The Director of Recruitment, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1, quoting Ref. No. 27324/5.

Research Assistant in Concrete Technology—The Professor of Concrete Technology, City and Guilds College, South Kensington, London, S.W.7.

Educational Psychologist—The Director of Education, Guildhall, Kingston-upon-Hull.

Assistant Professor (honours graduate) **in Mechanical Engineering**, and **Lecturers in Mathematics** (one Lecturer, with honours degree or equivalent qualification, in Electrical Engineering and one Lecturer, with honours degree or equivalent qualification in Metallurgy), at the Royal Naval College, Greenwich—The Secretary to the Admiralty (C.E. Branch 1), Admiralty, London S.W.1.

SELECTION FOR THE UNIVERSITIES

ONE of the outstanding features of the recent report of the University Grants Committee was its concern that, in the expansion of the universities of Britain, academic standards should be maintained or even improved, and that with the increased numbers of university graduates there should be no sacrifice in quality. This implies a greatly increased supply of freshmen of high quality; although there is little direct evidence on this point, there is no doubt that the schools could supply students well in excess of the present capacity of the universities.

This position is due in part to the numbers of older students in the universities whose training has been interrupted by national service. More than a third of the students at present in the universities of Britain are in receipt of grants under the Further Education and Training Scheme, or a total of more than 28,000 out of 77,000. Nevertheless, it cannot be assumed that, when this proportion of ex-servicemen diminishes, all the places will be available for younger undergraduates. The University Grants Committee considers that a limit should be put to the present overcrowding and consequent stress and strain, and its report implies that building up again even to the present numbers, still less the completion of the recommended expansion, should wait upon the recruitment and training of university staff and the physical expansion which will permit a normal university life and the maintenance of academic standards.

Although the Working Party on University Awards appointed by the Minister of Education in April 1948 was instructed to take account of the termination of the Further Education and Training Scheme, as well as of the increased numbers at the universities, and the probable abolition of the four-year grants for intending teachers, its report* makes surprisingly little reference to this question of quality and the maintenance of standards. Its recommendations will indeed, if accepted, sweep away many anomalies and irritations in the present system of awarding State and local scholarships. It is recognized that with the increased number of scholarships, it is unlikely that, as in the past up to 1947, State scholars will all be able to go to the universities of their choice; but the majority of the 'working party' considers they should be allowed to hold their scholarships at any university to which they may gain entry. The fundamental problem, however, is not the distribution of State scholars but the selection of students as a whole for admission to individual universities; and while the 'working party' advances a proposal for a university clearing house, on which Dr. W. W. Grave has reservations, it suggests that this larger question requires careful study.

The recommendations for raising the income-level above which a parent has to pay the whole of a State scholar's expenses, namely, from £1,500 to £2,000, and for increased maintenance grants and allowance, will ease a 'means test' which at present bears heavily on middle-class families. The clarifying of the principles on which State awards are based should encourage the adoption of similar principles for local awards, and disarm some criticism of the continued predominance of the county awards. The abolition within the next three years of four-year grants to intending teachers is also recommended, in favour of provision for the degree course through the normal scholarship channels and continued finance of the students in the professional year by the Ministry.

---

* Ministry of Education. University Awards: the Report of the Working Party on University Awards appointed by the Minister of Education in April 1948. Pp. iv+26. (London: H.M. Stationery Office, 1948.) 9*d*. net.

The wider implications of these recommendations, however, need to be considered much more fully. In the first place, since the local authorities are urged "to extend their arrangements to include all eligible students accepted and recommended by universities who have reached the advanced standard in two subjects in the examination for the General Certificate of Education", all financial barriers to university education are in effect down. As the 'working party' itself puts it, to-day "Reasonable opportunity exists for the ablest students to reach the university irrespective of means". With the removal of anomalies and of limitations on those opportunities as recommended in this report, it is imperative that further thought should be given to the numerical aspect, the financial cost to the State and the question of selection.

It is with this last aspect that the universities are most vitally concerned, and although the 'working party' places squarely on the universities the responsibility for recommending awards both of open and of local scholarships—that is, of selection—it scarcely seems aware, except for Dr. Grave's dissenting note, of the administrative and other implications. The universities were inadequately represented on the 'working party'; and Dr. Grave himself, in emphasizing the speculative character of the estimated figure of 5,000 given in the report for the number of places which will continue for the present to be filled by students who do not need or do not qualify for awards from public funds, suggests that the university authorities should have been consulted before this forecast was published. The basis of this estimate is the assumption that the annual intake of students by the universities will continue at a level of 18,000 as against 12,000 before the War, and that of this total at least 4,000 will be suitable candidates for open or State awards. In normal times, a further 2,000 will consist of overseas students or others who are not eligible for awards from public funds. Assuming further the discontinuance of the four-year grants for intending teachers in accordance with its own recommendations, the 'working party' suggests a minimum of some 7,000 awards to be made through local education authorities. It is this figure which is challenged by Dr. Grave, who is clearly anxious that the pressing need for university graduates will not result in a lowering of standards for admission. As he rightly observes, once standards are lowered it is very difficult indeed to restore them.

The University Grants Committee, from its recent report, is clearly fully alive to this danger, and it is to be hoped that the Minister of Education will consult the universities very fully and satisfy himself and the universities that conditions detrimental to the maintenance of academic standards are not prolonged or even made permanent by the premature adoption of a scale of awards too high for present conditions. The University Grants Committee, moreover, has the backing of the Nuffield College statement, and both bodies are far more representative of university opinion in Britain than the 'working party', only three of whose seventeen members came from the universities. If the university authorities, in the present circumstances, are unable to recommend for awards as many candidates as the report contemplates, they will have too much informed opinion behind them fairly to be accused of placing unjustifiable obstacles in the way of deserving students.

It is to be hoped, therefore, that the Minister of Education will give his support first to the proposals for the physical expansion of the universities and the provision of staff and buildings on a scale which will put a speedy term to the present overcrowding, and he can well decide that the number of public awards for 1951 shall be rather lower than the 'working party' suggests without denying a chance to anyone of real ability. In the debate in the House of Commons on December 17, the Minister of Education, while making it clear that the report had not yet been accepted, indicated that it might be concluded that the earmarking of students for the teaching profession before they entered a university would be discontinued and that, along with the considerations advanced in the debate itself, he would take full account of the representations which might come to him from the universities.

The fact that, as Mr. Tomlinson disclosed, awards are still being made under the Further Education and Training Scheme at the rate of 400 a week to students who were called up before September 30, 1947, may postpone the need for decision for a little while; but it is well to be quite clear as to what is involved in the general agreement that no one should be barred by poverty alone from a university education. As the University Grants Committee points out in its report, when the great majority of students are subsidized, it may not be possible to stop short, subject to a means test, of subsidizing all; and in spite of the difficulty of defining what is meant by "benefit of a university education", it will be necessary to face an entirely new problem of selection.

The University Grants Committee starts with the assumption that the universities must not be deprived of effective choice of their own entrants, and in this it is clearly supported by the 'working party'. The Committee also recognizes that it is desirable to exclude one type of student whom the possession of means once enabled to secure admittance —the riotously living passman, sometimes of athletic promise, on whom the university as an agency of culture made small dent. There is equally the problem of identifying at the stage of entrance to the university the other type of student, who gains much from the university and whose usefulness to the world is much enhanced by his stay there although he is not of outstanding intellectual ability. Even if, as the University Grants Committee appears disposed to agree, the removal of certain obstacles to access to the universities has eliminated also a measure of selection and lowered the average quality, the 'working party' may well be right in holding that only the adoption of its own recommendations regarding local scholarships will avoid a serious shortage of graduates for the various professions.

As to the basis of selection, the University Grants Committee merely observes that this is an unsolved problem to which the universities must now address themselves. Examination by itself will not suffice, nor will intelligence tests contribute much. Selection by interview and on the basis of reports from schools has the advantage of elasticity, but is open to the suspicion that the scales may be weighted unduly in favour of the socially eligible candidate of athletic prowess and pleasant manner and address. The 'working party' agrees that, for a considerable body of students of good academic capacity, school examinations by themselves cannot be a reliable test of ability. It suggests that the university should consider applications mainly on the grounds of the ability, attainments and inclinations of the applicants, their personality and character and the degree of competition from the other applicants. It believes, however, that more varied methods of selection are needed, and considers that the university authorities should be at liberty to interview a candidate and to apply for a suitable confidential report from the school.

Nor is this all. One other type of applicant at least, namely, those who, having left school at about fifteen and pursued their general education by part-time study, may prove to be well qualified for a university course. The 'working party' proposes that a certain number of such students should be selected on the ground of their record and intentions, supplemented by an appropriate written examination, and that the applicants should pass through a selection procedure similar in principle to that used by the Civil Service Selection Board. The final decision should rest not with the testing board but with a final selection board, constituted by the Ministry of Education, and on which the universities would be represented. This scheme would obviously remove the disadvantage at which such part-time students are placed in the ordinary written examination, and the 'working party' wisely suggests that the scheme should be tried at first on a very small scale. Dr. Grave objects to universities being asked to accept the recommendations of any final selection board, apparently basing his criticism on the Ninth Report from the Select Committee on Estimates (Session 1947–48), which discussed the Civil Service Selection Board (London: H.M. Stationery Office, 203, 205; 1948. 2*s*. net).

The selection of university students was one of the points made in the Fabian Society report, "Universities and the Future", in October 1947 (London: Fabian Publications, Ltd. Fabian Research Series, No. 120, pp. 33. 1*s*. net). Discussing the question, "Who Shall Graduate ?", it is emphasized that a comprehensive scholarship system is also essential to ensure that, whether the universities expand or not, they recruit the best possible material and draw fully upon the country's reserve of talent. The report accepts more readily than the University Grants Committee the opinion of the Barlow Report that there is an ample reserve of intelligence in Britain to allow both doubling university numbers and at the same time raising academic standards. No opinion appeared to be expressed on this point at the discussion in Section L (Education) of the British Association meeting at Brighton on "Selection at the University Level" (see *Nature*, October 16, p. 626); but successive speakers recognized the difficulty of finding a solution for the problem, and also the need for an experimental approach.

This, however, is not all. Whatever method of selection may be devised, its adoption by the universities of Britain will involve heavy administrative responsibilities with which many of them are at present ill-staffed to cope. No doubt the University Grants Committee was not unmindful of this aspect in its observations on administration; but the magnitude of those responsibilities may well be a further reason for proceeding with caution. The points at issue, in fact, are essentially those of method and of timing, and the whole trend of the Minister of Education's remarks in the recent debate on university awards suggests that the recommendations of the 'working party' will not be implemented hastily or without due forethought and proper consultation of the universities, the weak representation of which on the 'working party' has rather diminished the weight of its recommendations. If that course is adopted, we should simultaneously be on the way to the thorough understanding between the universities and the schools which Mr. C. R. Morris rightly stressed at Brighton, and which Dr. J. F. Mountford had previously urged at the Home Universities Conference in September 1947.

A FORGOTTEN HISTORY OF BOTANY

Botanik der Gegenwart und Vorzeit in culturhistoricher Entwickelung

Ein Beitrag zur Geschichte der abendländischen Völker. Von Karl F. W. Jessen. (Pallas, Vol. 1.) Pp. xxii + 495. (Waltham, Mass.: Chronica Botanica Co.; London: Wm. Dawson and Sons, Ltd., 1948.) 6 dollars.

THIS volume is the first of a series of classical scientific works which the Chronica Botanica Company aims at bringing into fresh circulation. Jessen's book appeared in 1864, eleven years before the publication of the well-known "History of Botany" by Sachs; but, while a copy of the original or of the English translation of the latter is to be found in every botanical library, Jessen's book will be known to very few in Britain. In actual fact the two books supplement one another to a very considerable degree, for, whereas Sachs' history begins with the early sixteenth century and gives little insight into the state of knowledge about plants among the ancients and during the Middle Ages, the first ten chapters of Jessen's book are devoted to these matters. After a brief consideration of the little that is known of plant studies among the early Indians, Egyptians and Babylonians, successive chapters deal with the state of botany among the Greeks and the Romans, during the early Christian era in Eastern and Western Europe and among the Arabs. A further four chapters dealing with the commencement of scientific studies in Western Europe brings the consideration to about the middle of the sixteenth century.

Jessen's book is, moreover, not a mere history of botany, but relates the progressive development of knowledge about plants to the general state of culture and of science as a whole at different periods. In fact, several of the earlier chapters contain as much information on the social history of the time as on the momentary state of botanical knowledge. It is this cultural approach that, as the editor remarks, renders Jessen's work unique. It carries with it also a different treatment of the subject-matter, since, in place of the separate consideration given to morphology and classification, anatomy and physiology by Sachs, Jessen in general discusses the state of the subject as a whole in each historical period.

The last ten of the twenty chapters into which the book is divided deal in the main with botanical history during the post-reformation period ; in fact, one is devoted to the re-orientation of science which followed in the sixteenth and seventeenth centuries. The gradual development of systematic botany from its early beginnings to the middle of the nineteenth century is admirably traced and illustrated in tabular form at the end of the book, while other branches of botanical science receive a due share of attention, but are not as fully treated as in Sachs' history. The excellent chapters on agriculture and horticulture and on popular science and botany in the eighteenth and nineteenth centuries are part of the special framework of the book.

Jessen's history is very readable, and usually succeeds in avoiding long lists of names which tend to become tedious. Those who have contributed the lion's share in the advancement of botanical knowledge occupy the foreground, and due credit is given to the part played by the various European countries in this process. A list of botanical journeys and a good index add to the value of the work.

F. E. Fritsch

THEORY AND PRACTICE OF SUPERCHARGING

Supercharging the Internal Combustion Engine

By Prof. E. T. Vincent. Pp. viii+315. (New York and London : McGraw-Hill Book Co., Inc., 1948.) 30*s*.

PROF. VINCENT has written an excellent book and is an enthusiastic exponent of his subject. The fundamentals of all aspects of supercharging are dealt with, and although the major part of the book is devoted to aircraft practice, there is much that is applicable to all forms of supercharged engines, including a chapter on the Diesel engine.

The author states in the preface that he is writing for "persons not directly connected with the theory or development of superchargers" ; the needs of such persons are adequately catered for. Those interested only in air compressors will find that the chapters on these machines form a comprehensive text-book in themselves. The types of compressors described include reciprocating, rotary constant displacement, centrifugal and axial flow, and an account of the theory of each is given. An interesting chapter on surging in the centrifugal compressor is included. The subject of supercharging itself is dealt with fully, and there are chapters on the theory of the supercharged engine cycle, performance estimating, testing, engine-driven superchargers and turbo-chargers. The book is profusely illustrated with diagrams and photographs, and a number of useful charts of the properties of combustion gases are provided.

In an early chapter on thermodynamics the author shows a nice appreciation of what should properly be left out of a book of this type, where the emphasis is on applied rather than fundamental thermodynamics. In no less than three places the reader is advised to consult a text-book of thermodynamics for a more rigorous treatment of certain points, such as the statement that entropy and internal energy are functions of the state of a body. Obviously, full discussions of such questions are outside the scope of this book, and the author has been very wise in not allowing himself to become involved in them. It is a pity that more authors do not follow this example. On the other hand, difficult problems which are not usually found in text-books on thermodynamics are not shirked. Steady flow, for example, which is of fundamental importance to engineers and which is treated inadequately, if at all, in most text-books, is fully discussed.

E. G. Sterland

GEOLOGY OF THE LIZARD DISTRICT

Memoirs of the Geological Survey of Great Britain

England and Wales. Explanation of Sheet 359 : Geology of the Lizard and Meneage. By J. S. Flett and J. B. Hill. Second edition, by Sir John Smith Flett. Pp. xi+208+11 plates. (London : H.M. Stationery Office, 1946.) 7*s*. 6*d*. net.

THE Lizard district had long been famous as a field of geological research and controversy prior to the publication in 1912 of the Geological Survey Memoir on it, and on many of its petrological, structural and stratigraphical problems there was scarcely a general consensus of opinion. This second edition, by the late Sir John Flett, one of the original authors, reveals him in the full maturity of his scientific judgment and mental vigour. It has been entirely rewritten after a re-examination of the area that followed his retirement from the directorship of the Geological Survey in 1935. Many will visualize in these accounts of the cliffs and exposures "alongside the path leading from the hotel to the beach" that powerfully built figure with deliberate step and penetrating all-embracing eye.

The new edition of the one-inch geological map which appeared in 1934 contained substantial changes in the age-grouping of the sedimentary rocks, which resulted from Prof. W. H. Lang's attribution of a Devonian age to the plants assiduously collected by Miss E. M. Lind Hendriks, and from Dr. C. J. Stubblefield's recognition of supposed Ordovician *Orthis* as a Devonian *Chonetes*. The significance of these changes is fully discussed. Regarding the age of the best-known Lizard rocks—the serpentines, gabbros and hornblende schists—Sir John ably presents the evidence; but generally reserves judgment.

The geological description is reduced from 263 pages in the first edition to 178 pages. In the introductory sections, geomorphology and soils receive considerably fuller treatment, and the interrelation of these with the underlying rocks is stressed throughout. These beneficial changes, the incorporation of new material, and the doubling of the number of text figures, especially maps, has, of course, involved the elimination of much detailed descriptive material. Lucid general descriptions and balanced critical discussion are preferred. The result is a combination of simplicity, clarity and scientific accuracy in a high degree. It may be that this work will be considered as representing what the eminent author in the fullness of his administrative and scientific experience regarded as desirable in an official memoir. Nevertheless, because of the elimination of much detailed description of important exposures, it might still be claimed that the old edition remains a valuable work of reference. A reservation should therefore be made that this effective compromise between a rather heavy, fully documented memoir and a much shorter explanatory guide does not necessarily represent a precedent of general applicability.

THE ART OF GRAFTING PLANTS

The Grafter's Handbook

By R. J. Garner. Pp. 223 + 24 plates. (London: Faber and Faber, Ltd., 1947.) 15*s*. net.

IN no branch of horticulture has so much ingenuity and manual dexterity been shown as in the art of grafting and budding. Over centuries, gardeners have taken pride in devising new methods by which two or more plants of different origin may be made to combine into a single entity, often for no reason other than to show their skill or originality, though sometimes to improve genuinely upon existing methods. Mr. R. J. Garner has probed deeply into the literature to discover as many of these ingenious devices as seemed to him worthy of preservation, and out of many hundreds he has put on record some eighty-odd methods of grafting, including a dozen or more of budding. All, or nearly all, are accompanied by unusually clear line drawings of the stages in each method, which help greatly to make plain the description in the text. If the book did nothing but bring together these scattered records and preserve them in collected form, it would have achieved something of historical value.

But the author is far more than a seeker into the past; he is a practical propagator of twenty years experience and a scientific man at the same time, and he has used his experience and his critical faculties to bring out the value of particular methods in particular cases and to show how a recondite or unusual means of manipulation may have a scientific justification in special circumstances. More than that, he has brought together the most up-to-date findings of research and the best traditional practices in the field of propagation as a whole, for he deals not only with the methods of grafting *per se*, but in the earlier chapters he also describes the methods of root-stock propagation and scion-wood preparation, which involves a discussion of many aspects of the problem.

The book is one which must be of the greatest value to the professional horticulturist, the amateur, and the student, all of whom will find in its pages not only guidance in technique but also clear exposition of underlying principles. A word of praise is due to the printers and publishers for the admirable type and format and, above all, for the clarity of reproduction of the author's own exceptional drawings and plates. Only too often photographs in a book of this type serve little useful purpose, other than presumably to increase the sales-value of the book; in this case every plate is a valuable illustration of some special point.

R. H. STOUGHTON

THEORY OF THE STRENGTH OF METALS

Report of a Conference on the Strength of Solids (1947)

Pp. 162. (London: Physical Society, 1948.)

THIS volume is a collection of papers given at a conference in Bristol in 1947 (see *Nature*, **160**, 696; 1948) together with a few additional papers. The solids dealt with are almost exclusively metals. The volume is divided into four parts of unequal length under the headings: "Creep and Plastic Flow" (70 pp.), "Grain Boundaries and Recrystallization" (47 pp.), "Precipitation" (20 pp.), and "Fracture" (4 pp.). The papers of the first part are concerned mainly with the deformation of metals associated with movement of dislocations. Dislocation theory has made good progress since the previous Bristol conference in 1939, and in the present volume many of the mechanical properties of metals are plausibly explained in terms of dislocations. The suggestion that solute atoms, such as carbon and nitrogen, may migrate to the neighbourhood of dislocations and hinder their movement gives an interesting interpretation of the yield phenomena in mild steel; and a first treatment of dislocation dynamics gives a plausible explanation of the multiplication of dislocations necessary to explain deformation by gliding. An interesting account is given of an electron microscope and diffraction investigation of slip in aluminium crystals. A notable omission is that a section, containing nine papers on creep and plastic flow and another of six papers on grain boundaries and recrystallization, should contain no papers on grain-boundary creep. The third section contains some good work on hardening of metals by the oxidizing *in situ* of solute atoms having a sufficient affinity for oxygen, and also a paper on the trapping of electrons in silver chloride, which raises the possibility of photographing dislocations.

In a volume entitled "The Strength of Solids", it is surprising that so little attention is given to fracture, and it leaves the impression that even the elements of a theory of the fracture of metals has yet to be given. Nevertheless, in view of recent progress in the study of the plastic properties of metals, we may look forward to a report on a not too distant conference on the strength of metals which does not belie its title.

C. GURNEY

TRYPANOSOMIASIS IN AFRICA

IT is not always possible to contemplate with such pleasurable anticipation a series of Government publications such as those dealing with varied aspects of trypanosomiasis in Central Africa—a truly gigantic problem. This is discussed in the four important communications now published*. These reports form a series prepared for the Tsetse Fly and Trypanosomiasis Committee appointed by the Secretary of State for the Colonies and edited for publication by the staff of the Bureau of Hygiene and Tropical Diseases. It is right that it should be emphasized that this difficult task has been performed with that thoroughness and skill which are the hallmarks of this excellent institution. By so doing they have been embellished with a scientific *finesse* which will be appreciated all the world over.

The vastness of the trypanosomiasis problem which confronts the Colonial Governments and the Colonial Office to-day is emphasized in a popular appreciation. The havoc caused by tsetse flies in Nigeria, for example, extends over a country seven and a half times the size of England, so that one-fifth only of this huge territory is safe for men and cattle. On the Gold Coast, over the entire area of 91,840 square miles, these flies prevent the people from keeping the large-humped zebu cattle which should contribute enormously to their meat supply; thus they are compelled to rely upon their own native dwarf unproductive breed which is more resistant to trypanosomiasis. The third great West African Colony —Sierra Leone (27,500 square miles)—is quite over-run with tsetse, and endemic sleeping sickness in man occurs in one-tenth of the country, so that the same dire cattle problems present themselves and large numbers succumb to this disease. Though comparatively smaller, the whole of the Gambia (4,130 square miles) is infested with tsetse, while human sleeping sickness is sporadic; but nowhere can the larger and more economic cattle types be maintained.

One of the more drastic remedial measures which have been suggested is the extermination throughout 'fly country' of the numerous dog-faced baboons upon which these flies engorge themselves—a task more easily said than done.

In Uganda we learn of extensive pastoral areas which, some forty years ago, maintained flourishing herds of healthy cattle and now are clothed with impenetrable bush. In one epidemic, within three years, 200,000 natives, inhabitants of Busoga Province, were exterminated. To those who study the food problems of the world—and there are many at the present moment—it comes as a shock to learn that in all the East African Colonies there are said to be only some 14 million head of cattle to support more than 15 million people, and that this deplorable disproportion is to be ascribed to the tsetse fly alone.

The bionomics of some ten species of *Glossina* are dealt with in these reports. This is a field to which British entomologists have devoted special skilled attention. Each species has its own particular habitat and maintains its own peculiarities. Some can tolerate extreme ranges of humidity and temperature, whereas others avoid dry zones. Some thrive in the forest shade, others avoid it. Most of this information is contained in the exhaustive report by Dr. T. A. M. Nash—a document of some seventy-five pages, illustrated by sixteen topographical photographic plates, of outstanding excellence, and an appendix containing fifteen beautifully executed maps, which we understand are the most accurate and detailed ever published on this subject.

The largest of the West African cattle—the humped zebu—is the breed with the least resistance to trypanosomiasis, so that it cannot be kept in belts where *Glossina morsitans* abounds; therefore, bovine trypanosomiasis is most serious in northern Nigeria, where these cattle are dominant.

The riverine tsetses, *G. palpalis* and *G. tachinoides*, carry most of the sleeping sickness to man. The bulk of this human disease occurs in the savannah woodland zone and, broadly speaking, the disease appears to be absent from the main forest belt. Eradication of the tsetse with the means at present at disposal is a Herculean task, and it is not possible to go deeply into this subject. In short, it involves the clearing of vegetation against the tsetse, as each particular species preserves its own peculiar botanical association and only too often do these radical measures clash with the interests of the agricultural and forestry departments. This is gathered from Nash's own story of the Anchau Rural Development and Settlement Scheme. Here is unfolded a tale which should warm the heart of all true patriotic Britons. The Anchau district is in the Zaria province of northern Nigeria, where in 1934 it was found by Dr. N. E. W. Anderson that no less than one-third of the population had sleeping sickness and that the bulk of the area was infested by *G. tachinoides* The Anchau settlement is the first large-scale attempt at rural development to be made in British West Africa, and marks the first occasion in that country in which the fly has been eradicated from a corridor 70 miles in length and covering an area of 712 square miles. The carrying through of this complete scheme has occupied some ten years and has entailed the co-operation of the Forestry, Veterinary and Geological Departments of the Nigerian Government. The scheme has now been completed at the comparatively cheap cost of £95,000 spent over a period of five years. That it has been well spent, and that it has afforded a demonstration of paternal Colonial Government in the best sense, a study of this fascinating account amply proves. In the Anchau district 3,700 people were moved out of 200 square miles of country, and eventually the whole population of 13,000 was settled into an area of 170 square miles.

We are given a glimpse of a primitive African town. It was indescribably filthy. Some 2,500 lived within a town wall which surrounded only 0·118 square mile, giving a population density rate of 21,200 to the square mile. On the weekly market days, about three thousand additional visitors would crowd into it, constituting a seething mob, all coughing, sneezing and spitting, owing to the peppers on sale in the tumble-down booths, so that any of the prevalent diseases spread rapidly to the surrounding villages after market days. The town was traversed by sunken footpaths winding between high mat fences, ankle-deep in expectorated sugar cane. Wooden clogs were worn because of the mud. Stinking borrow and dye pits mingled their smells with the all-prevailing stink of human excrement. For defensive reasons the town had been built on the edge of a marsh, with two tsetse-infested streams on the west and south and, in addition, these flies swarmed in the thicket-choked moat of the town wall which the people refused to clear because of ancient superstitions—but it *was* cleared and Anchau has survived. Mosquitoes came up at dusk from the marsh in their myriads. For years all beasts had been slaughtered on a piece of blood-soaked ground, which was littered with offal and bones, thereby providing a meeting-place for vultures and hyænas, and the dead had to be buried inside the town, to prevent desecration by these ghouls. In the wet season, the guinea corn, fourteen feet in height, choked the few remaining open spaces. Water was obtained from the swamp or from filthy wells sited within a few yards of a pit latrine.

* Colonial Office. Tsetse Flies in British West Africa. By Dr. T. A. M. Nash. Pp. 78+15 maps. 30*s*. net. The Anchau Rural Development and Settlement Scheme. By Dr. T. A. M. Nash. Pp. 22+4 plates. 3*s*. 6*d*. net. Trypanosomiasis in British West Africa. By Dr. T. H. Davey. Pp. 15. 2*s*. net. Trypanosomiasis in Eastern Africa, 1947. By Prof. P. A Buxton. Pp. 44. 3*s*. net. (London: H.M. Stationery Office, 1948.)

Such is the lurid picture painted of old Anchau, the district headquarters. How all this has been changed, how a model township with brick-built bee-hive huts in model compounds, with standard types of new wells, spacious well-planned market-place, slaughter-houses, etc., has been built, are well illustrated by a series of excellent aerial photographs. There follows a number of suggestions from the lessons which have been learned. More than 18,500 fruit and shade trees have been distributed throughout the corridor. A successful pig-breeding industry has been started which brings much wealth to the peasant farmer. Tsetse have been eradicated from 610 square miles of country, necessitating the clearing of 540 linear miles of stream, so that now some 50,000 people can live out healthy lives in a tsetse-free country.

There are some amusing interludes, such as the conflicting interests between the afforestation enthusiasts and tsetse-minded entomologists. Thus the planting of innocent papaya trees provided an ideal breeding place for *G. tachinoides* in the middle of the town and they had to be cut down. The presence of sacred trees in the streams caused much trouble. The village headman would suddenly announce that the work was nearing a spot where any man would die who entered the grove, and then work would come to a standstill. This nuisance was soon avoided by inducing the old man to exorcise his evil spirits on to a neighbouring hill, when everyone appeared to be satisfied and the prestige of the gangman was proportionately enhanced. To mark the transition from the bad old days and the transformation from a sink of pestilence, the new town of Anchau has been named Takalafiya,' which means "Walk in Health".

Dr. T. H. Davey's "Trypanosomiasis in British West Africa", a rather shorter document of some 15 pages, includes a general survey of West Africa and embraces the Anglo-Egyptian Sudan, French West and Equatorial Africa, the Belgian Congo and Liberia. Though not so detailed as the other reports, it contains a summary of useful information both on human and cattle trypanosomiasis.

In Prof. P. A. Buxton's "Trypanosomiasis in Eastern Africa, 1947", we are presented with a somewhat different problem. Many important points are discussed in the author's own characteristic and philosophical manner in a series of 275 paragraphs and in a space of 44 pages. The situation in East Africa differs in many important particulars from that in the West African Colonies. The geographical features of mountains, valleys and fertile plains present an entirely different picture with its own peculiar vegetation and fauna. Whereas sleeping sickness is conveyed from man to man direct by tsetses in the west, here the human disease is interconnected with big game and the fly which is their constant companion—*Glossina morsitans*. The cattle problem is even more serious, because the wild animals constitute a reservoir of trypanosome infection for them.

The fact has to be faced that, until some better preventive measures are devised, cattle and big game cannot co-exist. An alarming feature is that no doubt serious advances of the fly have recently taken place, especially by the closely related 'game tsetses' (*G. morsitans, G. pallidipes and G. swynnertoni*). This last-named insect was discovered by the late C. F. M. Swynnerton, who was the first to undertake tsetse survey, research and reclamation in Tanganyika in 1921. Swynnerton was a remarkable man, essentially a good naturalist, without any scientific training; but he possessed an immense knowledge of insects, game, plants and Africans, and he could envisage in his own mind the whole problem in a manner no one else has ever attained. More recently, particularly in Tanganyika, field workers have begun to mark flies with spots of paint. This has led to knowledge about their length of life under natural conditions and the distance covered by a fly. A system was then developed, depending on the use of more than one colour, applied to particular spots on the fly, so that it was possible to indicate where and when the fly was first caught, together with information about recaptures. By the use of these methods, entomologists were able to unravel the habits of *Glossina*. They showed that they had particular breeding places, feeding places and resting haunts, and they were able to determine these in terms of characteristic trees and bushes. Much interesting work has been done on the biology of *Glossina morsitans*. This insect lives in a large number of types of vegetation in different parts of its distribution. The greatest part of its range is in 'miombo', a thin deciduous woodland, composed of many types of tree, especially *Isoberlina* and *Brachystegia*; but in other parts it frequents *Acacia* thorn bush, whereas in Ankole, Uganda, it lives in thickets of thorn and other trees growing on large ant-hills in open grassy plains. In all these diverse environments the insect exercises a precise choice, and only feeds, rests or deposits larvæ in very limited spots. It is reasonable to believe that this precise choice, which renders discriminative clearing possible, is partly due to micro-climate.

In Central and North Africa, conditions are generally simpler than in East Africa. The immense geographical variety of Kenya and Uganda, with their high mountains, rift valleys, coastal plains and so forth, is absent. Although *G. morsitans* is the dominant species, yet *G. pallidipes* is also dangerous and has been overlooked in certain areas.

Entomological work in East Africa has been mainly directed from the Tsetse Research Department, Shinyanga. This has already resulted in the settling of large areas in Tanganyika which were formerly occupied by tsetse. The total area reclaimed by this Department is 1,300 square miles. There are now, in the Shinyanga district, 175,000 tax-payers and 525,000 cattle. It is an impressive experience to fly, as Buxton has done, over this area and see cattle and grass and villages where there was at one time only bush and tsetse.

In Uganda, successful control of *G. palpalis* by clearing its waterside breeding places has been practised for many years. Some of these clearings are important because they protect considerable centres of population, especially Entebbe, and they also render safe the ferries where numbers of travellers used to be exposed to the bites of this fly.

The control of tsetse in Southern Rhodesia is essentially a battle against *G. morsitans*. It is the problem of protecting cattle. The principal method employed has been the eradication of game from certain areas, mostly in the higher regions of this territory. Here the Government proposes to make a total of 300–350 farms, each of 3,000 acres, which will be on land formerly occupied by *G. morsitans*.

It has only been possible to select a few of the most important and interesting features which are presented in this most remarkable and original document; but it may convey to the uninformed reader a small idea of the immense effort, both physical and mental, that has been expended by a handful of enthusiastic scientific workers for the benefit and development of the Dark Continent.

It is by a happy coincidence that a summary of this fine preventive work should be published at this very time, furnishing, as it most certainly does, an appropriate setting to the introduction of 'Antrycide', a discovery published in *Nature* of January 15. Together they form a fine consummation of the work of this team of British scientific workers, and undoubtedly bring eventual victory over the tsetse considerably nearer. This is an achievement of which everyone who is interested in the welfare of Africa should be proud, although its full import cannot as yet be measured.

Finally, we venture to assert that these reports, so inadequately here reviewed, constitute a model for the world to emulate. By our good deeds shall we be judged by future generations. Scientific work of this calibre forms the kernel of potent propaganda. We can therefore look forward to such time as the British representative, at some stormy meeting of the United Nations Organisation, can confront his detractors with these mighty African achievements, for no other nation, by its self-effacing and patient labours, has done so much for the health, prosperity and well-being of the untutored Africans whom fate has placed under its care.

PHILIP MANSON-BAHR

BEE BEHAVIOUR*

By DR. C. G. BUTLER

Rothamsted Experimental Station, Harpenden

FOR many years it has been realized that a well-developed social organisation is exhibited by every colony of honey-bees. We now know, thanks to the work of G. A. Rösch and others, that a highly efficient division of labour exists among the worker bees of a colony, and that each worker bee has her own particular part to play in the economy of her colony. The nature of the duty which a worker performs at any given time is very largely, but not entirely, determined by her age, or, more correctly, by that state of physiological development to which she has attained at the time. But there are no hard and fast rules. If insufficient bees of nursing age are present to feed all the larvæ properly, the period of nursing is extended; similarly, if more than sufficient house-bees are present, their time is not wasted, and the position is readjusted by surplus house-bees becoming foragers at an earlier age than usual. The precise mechanism by means of which such adjustments are made is not yet fully understood.

By the time a bee is three weeks old, she knows the exact position of her hive relative to neighbouring objects in the apiary. If we take a bee of this age and release her a short distance away from her hive, she finds her way home largely, perhaps entirely, by sight. Later, however, as shown by the work of E. Wolf, when she becomes an established forager, two further senses come into play and aid her in finding her way back to her hive. These are a sense of distance travelled, and a sense of the direction in which she has travelled on her outward journey to a source of food.

Even after a bee has successfully relocated her hive on her return from a foraging expedition, she may experience considerable difficulty in finding the entrance if it has been altered in any way. For example, as shown by Butler, if the hive is turned through 90°, she will return to the exact place where the entrance has been hitherto. She settles on the nearest part of the hive to this position and proceeds to run about in all directions, frequently taking to the wing and re-alighting on the place where the hive entrance was situated previously. Eventually, after much running about she locates the entrance in its new position. On her return from subsequent foraging expeditions she does not go directly to the entrance but always goes first to the place where it was originally sited, alights there and runs round on the outside of the hive to the entrance in its new position. Ultimately she learns to fly round to the entrance, but never does so directly, always flying to its original position first and flying from there round the hive to its new location.

In a very similar manner to that in which she is able to find her hive on returning from the field, the honey-bee is also able to relocate a dish of sugar syrup or other source of food that she has found in the field. Provided that the source of food has not been moved, or its surroundings disturbed, the average honey-bee relocates it quickly and unerringly after she has visited it a few times. Let us suppose, for example, that we have placed a dish containing concentrated sugar syrup a short distance, say fifty yards, in front, north, of a fairly strong colony of bees living in an observation hive. It will almost certainly be a matter of hours or even days before a single bee finds the syrup. When a bee does find the dish, however, she settles upon it and proceeds to fill her honey stomach before returning to the hive with her prize. When she leaves the dish she performs a short orientation flight around it to help her to find it again the next time that she seeks it. Let us mark her with a spot of coloured paint so that we can recognize her again. If we watch her on her return to the observation hive, we find, in all probability, that she performs a little dance either on the alighting board of the hive or on one of the combs, every now and then pausing to pass some of the syrup that she has collected to other bees that have been paying close attention to her dancing. Presently, when she has given away the syrup she has collected, some to the house-bees for ripening and storage, and some to the bees of foraging age, she ceases to dance, cleans her eyes and antennæ, and leaves the hive, soon to reappear at the dish of syrup. A number of bees will have been observed to have been attracted by the dance, and some of them leave the hive while the dancer is still performing and eventually find their way to the dish of syrup, so that the number of bees visiting the dish increases. It will be realized that by means of the dance the bee that had found the syrup in the first place was able to communicate information concerning its existence to other bees. Some of these bees then left the hive to seek the syrup and, having found it, filled their honey-stomachs, made orientation flights around the dish to aid them to relocate it on future visits, returned to the hive and danced in their turn, thus informing other bees of their find.

---

* Substance of a Friday Evening Discourse delivered at the Royal Institution on November 5.

After a number of bees have found the dish fifty yards due north of the hive and have been marked so that we can recognize them again, let us put out further dishes of syrup of exactly the same concentration, west, east and south of the hive and fifty yards from it in each case. We then find that just as many fresh bees appear at each of the new dishes as appear at the old dish due north of the hive. Thus we see that, so far as we can tell, all the information that the dancing bees were able to convey to their sisters was that syrup was to be found somewhere outside the hive. They did not lead the newcomers to the syrup either by flying along in front of them, by leaving a trail of scent, or anything of that kind. Now let us repeat the whole experiment, except that we add a few drops of perfume, let us say oil-of-lavender, to the first or training dish due north of the hive. Plain unscented syrup is supplied in the other three dishes when they are put out. We now find that all the newcomers collect at the first or training dish only, ignoring the other dishes which contain unscented syrup of the same sugar concentration. It is clear, therefore, that by means of the scent in the syrup which the dancing bees gave to those bees which were attracted by their dances, the dancers were able to communicate to the other bees information concerning not only the presence of desirable syrup somewhere outside the hive, but also the scent associated with the syrup, which scent the following bees then sought, thus being led to the only dish which contained syrup with this scent, the one due north of the hive.

This, then, is part of the language of the bees, a language of dances, which were first described by Prof. K. von Frisch about the year 1923.

Von Frisch described two dances in 1923, a round-dance and a wag-tail dance. He suggested that by means of the round-dance coupled with the perfume of the species of flower from which she has collected the nectar, the dancing bee is able to pass on to other bees information regarding the presence and source of a supply of nectar; and that by means of the wag-tail dance similar information about a source of pollen is given. He did not consider that the dancer was able to indicate the direction in which such a source of food lay or its distance from the hive. Further epoch-making work published by von Frisch in 1946 has shown, however, that it was, as O. W. Park and other observers had thought, incorrect to identify the round-dance exclusively with nectar collection and the wag-tail dance with pollen collection. He stated in 1946 that if the food, whether it be nectar or pollen, is located at the distance of less than about one hundred yards from the hive, a round-dance is performed; if it is situated at a distance greater than one hundred yards, a wag-tail dance takes place. By means of the wag-tail dance a successful forager is able to indicate not only that she has found food at a greater distance than the one hundred yards from her hive and, of course, the perfume associated with that nectar, but is also able, apparently, to give to her sister bees an extraordinarily exact indication of this distance. The distance of the source of food from the hive is indicated by the number of turns, figures-of-eight, in the wag-tail dance that are made in a given period of time. Thus, for example, if the source of food is approximately three hundred yards away, the dancer makes about twenty-eight turns per minute, whereas if it is three thousand yards away she makes only nine turns in the same period of time. The length of the straight run which is interposed between the two loops of the figure-of-eight, and the rate of tail-wagging, increase slightly with increasing distance. Von Frisch does not appear to believe, however, that distance is indicated when the food source is less than about one hundred yards from the hive.

Von Frisch has also shown that the honey-bee is able to indicate the direction in which a feeding place lies, provided that such a feeding place is more than one hundred yards from the hive, by the direction in which she makes the straight run of the figure-of-eight, wag-tail, dance. If the run is made vertically upwards on the comb, this indicates that the feeding place is situated in the same direction as that from which the sun is shining at the time; conversely, if the run is made downwards, the source of food is to be found in the opposite direction to that from which the sun is shining. If the bee runs to the left at a certain angle to the vertical the food can be found at the same angle to an imaginary line drawn between the sun and the hive; and so on. Actually it has been found that the sun can be obscured by cloud without interfering with this direction-indicating mechanism.

It has been found that those bees which become interested in the dance of a returned forager follow her round and thus, presumably, learn the message which her dance conveys.

Now let us consider how a foraging bee, possessing these and many other complicated behaviour patterns, behaves in the field when she is working a more or less homogeneous crop of flowers for nectar. In order to simplify the study, my colleagues and I laid out an experimental field with artificial flowers. Each of these 'flowers' consisted of a Petri dish with a one-pound glass honey-jar full of sugar syrup inverted in it, a small piece of blue porcelain being placed on top of this reservoir to add a little colour. These 'flowers' were regularly arranged at twenty-yard intervals along the arcs of circles, each arc being twenty yards from the arcs on either side of it. The whole experimental area occupied part of a sector, of about 30°, of a circle the centre of which lay near the middle of a fairly large experimental apiary. Each 'flower' was supplied with syrup continuously, and once a number of bees were visiting them regularly the experiments were commenced. One fine day in June 1942, two bees were found to be visiting a 'flower' situated at a distance of about 360 yards from their hives. These two bees were marked so that they could be identified from one another and from all other bees. Continuous observation was maintained at this 'flower', and it was found that these two bees flew between their hive and this 'flower', collecting the syrup and carrying it home with great regularity. In the evening these same two bees were still visiting the 'flower' and had by this time made about a hundred and fifty return journeys in the day; they continued to visit this same 'flower' on subsequent days and never appeared to visit any other despite the fact that they had to fly over or near to a number of similar 'flowers' containing syrup of equal concentration. The same thing was found to be true of other bees visiting various 'flowers' in the experimental field. It therefore appears that so long as there is an abundance of syrup, or nectar, at a given source, bees will confine their attention to this one source for many hours and even for many days.

If we now proceed from this study of the territorial constancy of one or two bees to that of a small, but nevertheless much larger, population, we find that the same thing holds true. It must be pointed out, however, that although this behaviour is in principle probably the same as that which occurs when bees are visiting a natural crop of flowers for nectar or pollen, the time relationships are not of the same order on a flowering crop as on the dishes, since on flowers the time spent by a bee in collecting a load of food is usually much greater than the time spent by this bee in flying to and from her hive.

A number of observations have, of course, been made on natural crops of flowers such as willow-herb (*Epilobium angustifolium*), sainfoin, white clover, etc.; and it was found that bees do exhibit a remarkable degree of constancy to small patches of selected flowers growing in a large group of flowers of the same species. It appears to be reasonable to conclude from a study of the data obtained in these experiments that the honey-bee does not as a rule wander at random over a crop of flowers, but confines her attention to a small area of any crop, the size of this foraging area depending upon the conditions at the time. For example, if the flowers are scattered, then the foraging area of an individual honey-bee is likely to be much greater in extent than would be the case if the flowers were growing close together. The abundance of the nectar or pollen in the flowers also has a profound effect upon the size of the foraging area of each individual. C. R. Ribbands has shown, for example, that in some instances a single flower may for the time being serve as the foraging area of one or more bees. Of course, the foraging areas of individual bees overlap considerably, and if the population of foragers, and therefore the degree of competition, are sufficiently great, there is a further population of wandering bees superimposed upon this relatively fixed population. There is also, without doubt, a third population which is composed of scout bees which leave their hives without any preconceived ideas about what kinds of flowers they are going to work. Having tried a number of different kinds of flowers experimentally, they probably settle down in foraging areas on that crop which is yielding the richest and most abundant nectar or pollen.

It is now fairly clear that the fixation of an individual bee to any particular area of a crop of flowers of one species, and even to one species of flower, is not rigid, although it certainly appears to be the general rule. If, for example, bees are offered a choice between dilute and concentrated sugar syrup in two sets of dishes that have been placed at random in a given area, they will, unless the degree of competition is too great, congregate on those dishes which contain the syrup of the higher concentration. The same thing has been found to occur when syrup of a given strength and nectar are in competition with one another. Thus in some of his experiments Von Frisch found that it was difficult to induce his experimental bees to remain faithful to the dishes of syrup which they had been trained to visit, because flowers in the district contained nectar with a higher sugar content than that of the syrup in his dishes. Ribbands has also demonstrated that individual bees collecting nectar and pollen in a specially planted garden sometimes leave the species of flower from which they have been gathering food for some time and sample the pollen or nectar in a flower or two of another species. It would appear that should this new source of food prove to be more satisfactory than the previous one, they will often desert their old source and establish themselves in foraging areas on the new; but if it proves to be less satisfactory, they soon return to the old source. Even when they have become attached to a new source, they continue to visit a few flowers of the old source from time to time and may return to it once more.

It appears to be reasonably certain, therefore, that honey-bees do not wander over a crop of different species of flowers at random, visiting first one species and then another; but rather that they quickly become attached to one particular species and to a relatively small number of flowers of this species. From time to time, however, they will visit another species experimentally and, should it prove to be a more profitable source of food than that species, or, perhaps, those species, which they have visited hitherto, each bee will select for herself a foraging area in the stand of this new species of flower, and will remain faithful to it just so long as she does not discover an even more profitable source of food elsewhere.

CONCERT HALL ACOUSTICS

THE Acoustics Group of the Physical Society held a meeting on November 4 at the Royal Society of Arts to discuss "Concert Hall Acoustics". The object of the meeting was to bring together musicians, architects, engineers and men of science in a general discussion on concert hall acoustics, with particular reference to the new concert halls for London.

Before describing the discussion, it is important to outline the present state of theoretical knowledge. The most recent major contribution to the theory of acoustics of rooms has been made by P. M. Morse and R. H. Bolt[1]. These authors have analysed the behaviour of sound waves in rooms in terms of wave theory and the appropriate boundary conditions, and obtain exact solutions for rooms of simple shapes, and approximate solutions by perturbation methods for rather more complex shapes. However, the lack of practical knowledge of the acoustic impedance of the materials used internally in concert halls and the complicated shape preclude the direct application of the solutions, and it is necessary to use the simpler concepts of geometrical acoustics. The classical approach of W. C. Sabine[2] in defining the reverberation-time of halls has remained substantially unchanged, and it is Sabine's formula and the minor modifications to it that the architect must use when designing a new hall.

Mr. Hope Bagenal, speaking as an architect, gave a general review of the problem; there is, he said, no consistent London concert-hall tradition. The only contribution was Knightley's Queen's Hall (seating 2,000) in which convex splays were used round the orchestra to reflect the orchestral sound into the auditorium. Knightley also deliberately introduced resonant wood panelling, and this was effective in absorbing low frequencies and enhanced the balance of tone.

Mr. Bagenal described two older building types. The first was the large baroque theatre of the eighteenth century. Low-frequency absorption was good, due to the use of stucco on wood lath; middle- and high-frequencies were absorbed by the upholstery; and the baroque ornament diffused the sound adequately. These factors produced a very short reverberation-time and no echoes, and hence made possible an extreme rapidity of tempo. The other building type was the Leipzig concert hall derived partly from the halls of the Italian musical academies and partly from the early coffee-house rooms. This type was rectangular with a flat ceiling, giving a good distribution of sound. Boxes in the rear wall prevented echoes arising from end reflexion, but there was less absorption per cubic foot of volume than in the theatres. The reverberation-time was longer and consequently the tone was fuller. W. C. Sabine designed the New Boston Concert Hall (1,100 seats) after studying the Leipzig *Gewandhaus* (1,560 seats), and developed his formula for calculation of reverberation-time from these studies.

At this stage in the development of concert halls it had become possible by the development of empirical methods to build a good hall for an orchestra of 80, choir of 220 and audience of 1,500. But in recent years the requirements have changed. The orchestra numbers 120, choir 400 and the audience 3,000 or more. The baroque ornament has disappeared, and it is necessary to introduce elements to fulfil their acoustic functions and yet be in conformity with modern architectural style. Another modern requirement arises from the fact that in parts, at least, modern compositions are much louder than classical works. In Mr. Bagenal's opinion the largest halls are not suitable for the performance of works containing very quiet passages; in the rear seats these passages may even become inaudible. The maximum permissible distance between an orchestra of 120 and the rear seats is 140 ft., for smaller orchestras 120 ft.

Mr. Bagenal then defined the two main requirements for good concert hall acoustics, 'definition' and 'singing tone'. He explained 'definition' as the rapid delivery to the ear of all the pitch components of each note in a note sequence together with their proper order and beat. It also involves the proper hearing of transients. The design requirements to obtain good definition he described as free, direct paths for the sound, reflectors near to the orchestra, and glossy surfaces to reflect the highest frequencies. There is also the negative requirement of absence of echo. 'Singing tone' was defined as a choral character imparted to strings, and produced by reverberation.

In the light of these requirements Mr. Bagenal discussed two types of hall: the older rectangular type with side galleries, and the newer fan-shaped type with wide rear gallery and ramps. The rectangular type would have reflectors at the sides and above the orchestra. The floor seating could rise only slightly, and the orchestra platform would consequently have to be raised with steep platform risers. The definition might suffer from the screening of some players in the orchestra by others, but the random reflexions from the side walls would give good singing tone. The hearing at the back of the hall would be poor because of the long distance. The fan-shaped type would enable the seats to be steeply ramped, and the orchestra could then be placed on the same level as the front seats, providing good definition for all seats. But to prevent echo from the large rear wall, which is often concave, this wall would have to be absorbent, and this might reduce the reverberation and cause poor singing tone. The rear seats would be better than in the rectangular hall owing to the shorter distance. By the use of convex surfaces in the fan-shaped hall the reflexions can be randomized at will.

There is a modified type of hall which combines some of the features of the two types described above. This type is the stepped fan-shape, that is to say, the opening-out of the plan is achieved by a series of steps in the side walls, thus retaining the parallelism of the side walls.

In all types of hall the placing of the organ is difficult, and in a hall suitable for orchestral music the reverberation-time will be too short for good organ tone.

In the discussion that followed, Sir Adrian Boult, speaking as a conductor, stated that, if forced to choose, he would sacrifice definition for a good singing tone; he considered that the latter is essential for the beauty of music. Another conductor, Sir Malcolm Sargent, in a written contribution, obviously had an entirely different definition of singing tone from Mr. Bagenal's definition. Sir Malcolm referred to singing tone as being a function of the harmonics produced by a given instrument independently of its acoustical surroundings. He defined as 'resonance' in a hall the retention of the higher harmonics of the instruments without excessive absorption. Mr. Geoffrey Sharp, who spoke as a music critic, preferred singing tone to definition, on the somewhat opportunist grounds that at the present time the precision of the playing of orchestras is not sufficient to be affected by the acoustics, and that the singing tone reinforces the usually poor quality of strings. Dr. K. Rankl, another conductor, considered that a hall seating 2,500 people is the maximum size for good acoustics. If the public demand is too great to be accommodated in this size of hall, the same concert should be repeated two or three times. He thought that broadcasting acoustics should not be considered, for the requirements are quite different.

Mr. Clive Entwistle put forward, as an architect, a revolutionary plan to seat 6,000 in an annular hall with the orchestra in the centre. He claimed that the main advantage would be that the farthest auditor would be only 108 ft. from the orchestra, compared with 143 ft. for a fan-shaped hall seating 4,000. Mr. P. H. Parkin, speaking as a physicist, pointed out that this proposal assumed that sound is radiated equally in all directions by an orchestra, which is, in fact, not the case for the higher frequencies. Mr. F. Howes also took up this point as a music critic, and said that the 'address' of orchestra to audience would be lost to half the listeners.

Mr. T. Somerville (B.B.C.) described measurements made in two halls, the New Philharmonic at Liverpool and St. Andrew's, Glasgow. In addition to the usual reverberation-time measurements, pulses of sound at specific frequencies with durations of a few milliseconds were injected into the hall, and the resulting variation of sound pressure with time presented on a cathode-ray tube. In the Liverpool hall the build-up and decay of the sound pressure was uneven, whereas in the Glasgow hall the received pulses were sharply defined. This pulse technique was also described by Mr. J. Moir (British Thomson-Houston Co., Ltd.), who showed pulse records taken in a cinema. Mr. Moir claimed that this technique is the most useful for investigating hall acoustics, but stated that quantitative interpretation of the results is not yet possible.

Mr. Parkin (Building Research Station) summarized the results of a questionnaire sent to 175 expert listeners (for example, music critics), in which they were asked for their opinions of the acoustics of ten selected concert halls. The replies showed conclusively that the New Philharmonic Hall, Liverpool, was considered to have very good acoustics. The Royal Opera House, Covent Garden, and St. Andrew's Hall, Glasgow, are two other halls generally considered to be acoustically good. This 'operational research' approach, which bases the assessment of the acoustical properties of a hall on a statistical analysis of critical subjective estimates coupled with physical measurements, was also evident in Mr. W. A. Allen's contribution describing a subjective test made in a concert hall by six listeners. These listeners changed their position in the hall between items in a concert, and there was substantial agreement on the acoustic conditions at the various positions. Mr. Parkin also pointed out that since calculation gave only a rough guide when designing a hall, it would be advantageous to adjust the acoustics of a new hall while building, on the basis of measurements made when the hall was nearly finished.

Mr. R. Howarth (B.B.C.) stated that in a war-time B.B.C. studio the broadcasting acoustics were much improved by the replacement of the wooden orchestral platform by a solid structure.

Mr. H. L. Kirke (chairman of the Acoustics Group), in his summing-up, emphasized the value of meetings such as this in bringing together architects, musicians and men of science. It was obvious that exact definitions of the terms used are required, and that further and more detailed collaboration is necessary.

OBITUARIES

Dr. James Chumley

ON December 12, 1948, there passed away at his home near Edinburgh at the advanced age of eighty-six, Dr. James Chumley, thus bringing to an end a long life of service to biological science the more worthy of commemoration in *Nature* in view of the fact that most of his work was carried on unseen and unrecorded by publication under his own name.

In the closing years of the nineteenth and early years of the present century, one of the chief centres of zoological activity was the "Challenger" Office, Edinburgh, where John Murray supervised the working out of the immense collections brought home by H.M.S. *Challenger*. From a subordinate position in the office, Chumley rose to become Murray's secretary and right-hand man in the work of caring for the collections, distributing them for investigation by specialists and eventually editing the fifty volumes of "Challenger Reports" which may well be regarded as forming the foundations of the modern science of oceanography. Chumley claimed, no doubt justifiably, to be the only man in existence who had read every word of these reports.

In addition to his work in the "Challenger" Office, Chumley acted as secretary and treasurer of the Scottish Marine Station at Granton, built with funds subscribed by friends of John Murray, by the margin of a great quarry which had been invaded by the sea and converted into an immense natural aquarium. Attached to the Station were a large lighter with deckhouse laboratory moored in the middle of the quarry and humorously designated the *Ark*, and a small research ship of 30 tons, the *Medusa*. The Granton Marine Station served to introduce various zoologists, including the present writer, to the science of marine biology, and incidentally it may be regarded as the ancestor of the important Millport Marine Station of to-day, for the *Ark* and the *Medusa* were taken through the Forth–Clyde Canal in 1884 and utilized in the Clyde area for investigations supplementary to those of the *Challenger*. After the conclusion of this work in 1892, the *Ark* remained at Millport; it was drawn up on the shore and continued to function as a laboratory until destroyed by a storm in December 1900, an extension having already been provided which still exists as part of the present Station.

Murray's plans to return to the Clyde and take over the Millport Station were brought to nought by his sudden death by accident in 1914. The *Challenger* collections were handed over to the British Museum (Natural History), and Chumley was appointed a teaching fellow in the Department of Zoology, and later as lecturer on oceanography, in the University of Glasgow. There he continued to play the same active unobtrusive part as he had in the "Challenger" Office. The arrangement and cataloguing of the large library and the card catalogues of local fauna were in the main the work of James Chumley; and those in the Department of Zoology who published work during his twenty years in Glasgow owe him an inestimable debt for his ever-ready assistance in matters of bibliography and editorial revision.

As already indicated, Murray carried out, as an extension of the *Challenger* work, oceanographical researches in the Clyde sea area. So far as concerns physical oceanography, the results of these investigations were duly worked up by one of Murray's colleagues, H. R. Mill; but the zoological results had remained untouched. This blank Chumley proceeded to fill, and his first two years in Glasgow were devoted to working through the *Medusa* records with the idea of thereby laying a foundation for subsequent faunistic work. The result was his valuable "Fauna of the Clyde Sea Area", published by the Glasgow University Press in 1918.

JOHN GRAHAM KERR

Prof. W. J. Dann

PROF. WILLIAM JOHN DANN, professor of nutrition at the Duke University School of Medicine, Durham, North Carolina, died at his home on December 5. Prof. Dann was born in Bath, England, on November 9, 1904, and graduated at the University of Sheffield in 1925. Later he went to Cambridge, where he received the Ph.D. degree in 1932, after working under the direction of Sir Frederick Gowland Hopkins.

Dr. Dann, who had been at Duke University since 1935, became a recognized authority in the field of nutrition and the study of vitamins. He was a Beit

Memorial Fellow at the University of Cambridge between 1933 and 1937, and was awarded the degree of D.Sc. by the University of Sheffield in 1943.

For many years Prof. Dann served as an editor of the *Journal of Nutrition and Nutrition Reviews*, and as a member of the Institute of Nutrition. He was co-author of the book "The Determination of the Vitamins". At Duke University he did outstanding work and research on pellagra and other deficiency diseases, and the use of nicotinic acid in combating them. His death at the early age of forty-four involves a great loss to the University and to science.

WE regret to announce the following deaths:

Prof. L. Farkas, professor of physical chemistry in the Hebrew University, Jerusalem, on December 31.

Prof. Hermann J. Levy, formerly of the Technical College, Berlin, an authority on the economics of industrial assurance and of retail distribution, on January 16, aged sixty-seven.

Dr. J. Gilbart Smyly, formerly regius professor of Greek in Trinity College, Dublin, known for his work on the Tebtunis and the Flinders Petrie papyri, on December 25, aged eighty-one.

NEWS and VIEWS

Girton College, Cambridge: Dr. Mary Cartwright, F.R.S.

MISS MARY LUCY CARTWRIGHT, whose appointment as Mistress of Girton has been announced, is recognized as one of the leading pure mathematicians in Great Britain. A pupil of G. H. Hardy at Oxford, she gained the degree of D.Phil. at that University, but migrated to Cambridge in 1930, on her election to a fellowship at Girton. Her early work was on Abel summability and Dirichlet series. This was followed by a long series of papers on integral functions and functions regular in angle. Influenced possibly by J. E. Littlewood, she then turned her attention to inequalities for *schlicht* and related functions, and in 1935 made what is perhaps her most striking discovery, the inequality

$$|w(z)| < A(p)\,\mu\,(1-r)^{-2p}$$

for a function which takes no value more than p times in the unit circle. During the War, Miss Cartwright worked in an entirely different field, the theory of non-linear differential equations. The great practical importance of this field has long been recognized; but the mathematical difficulties are very formidable. The subject has advanced greatly as a result of the war-time work of Miss Cartwright, Prof. Littlewood and others. Miss Cartwright was elected a fellow of the Royal Society in 1947, the first woman mathematician to be so honoured.

Zoology at Sydney: Dr. P. D. F. Murray

DR. P. D. F. MURRAY has been appointed to the chair of zoology at the University of Sydney. Dr. Murray, who is a graduate of Sydney, first came to England as a research student to study under Dr. Julian Huxley at Oxford. He then returned to Sydney, where he held a lectureship in the Zoology Department. In 1930, having obtained a Rockefeller travelling fellowship, he returned to England to work at the Strangeways Research Laboratory, Cambridge, and in the same year was awarded the Smithson Fellowship of the Royal Society. He left Cambridge in 1937 to take a teaching post at Bedford College, London, and in 1939 he was appointed to a university readership in biology at St. Bartholomew's Hospital Medical College. Dr. Murray is well known for his studies on the developmental mechanics of the skeleton in embryonic life. In these investigations the potentialities of the mesoderm of the early chick limb-bud were analysed by isolating different regions of the rudiment and studying their development when grafted on the chorio-allantoic membranes of the egg. Dr. Murray also made an extensive series of experiments on the physiology of the heart rudiment, using the tissue-culture technique and observing the effect of various ions on the character of the beat. Recently he has returned to his researches on the problems of skeletogenesis.

Institution of Electrical Engineers: Capt. J. M. Donaldson, M.C.

CAPT. J. M. DONALDSON has been elected an honorary member of the Institution of Electrical Engineers in recognition of his distinguished contributions to electrical power engineering, particularly in the fields of generation, transmission and distribution; and for his services to the Institution. Capt. Donaldson was educated at Whitgift Grammar School, Croydon, and at Finsbury Technical and Central Technical Colleges. His first appointment, in 1897, was with the British Thomson-Houston Co., London, and he then studied American methods for four years in the United States and Canada. In 1906, he was appointed general assistant engineer to the North-Metropolitan Electric Power Supply Co., becoming a director of the Company in 1943. Under Capt. Donaldson's technical guidance the 'Northmet' system grew to be one of the largest co-ordinated electric power supply networks in Great Britain. He carried out much pioneer work in the field of supply, particularly in the use of steam at increased pressures and temperatures in the generating plants for which he was responsible. He now serves as a member of the Eastern Electricity Board. Capt. Donaldson was president of the Institution of Electrical Engineers in 1931, and has served as a member of a number of committees of the Council.

Mr. C. S. Franklin

THE twenty-seventh award of the Faraday Medal has been made to Mr. Charles Samuel Franklin for his distinguished work in radio engineering, and in particular for his original studies of short-wave wireless transmitting and receiving circuits and his invention of the beam aerial, by means of which the practical use of short-wave transmission for communication purposes was established. Mr. Franklin was born in 1879 and received his engineering and scientific training at Finsbury Technical College under Prof. Silvanus Thompson. In 1899 he joined Marconi's Wireless Telegraph Co., then known as the Wireless Telegraph and Signal Co., and was continuously associated with research and development in radio engineering with that Company until 1935, when he retired from active work. During his period with the Company, many outstanding developments stood to his credit, including reaction patents for wireless receiver circuits, the early British broadcasting stations, directional receiving systems for long-wave communication circuits, rotating beam aerials, short-wave wireless transmitting and receiving circuits, and in particular the beam aerial array associated with his name, which was the fundamental invention comprised in the beam system of wireless telegraphy. He also developed the concentric cable system, which is essential in television transmission practice. Mr. Franklin was the first recipient of the James Alfred Ewing Medal, instituted in 1936 in memory of Sir Alfred Ewing and awarded by the Institution of Civil Engineers for specially meritorious contributions to the science of engineering in the field of research.

American Association for the Advancement of Science: New President

PROF. ROGER ADAMS, head of the Department of Chemistry in the University of Illinois, has been appointed president-elect of the American Association for the Advancement of Science, and will serve as president during 1950. A former president of the American Chemical Society, Prof. Adams has received many honours for his work as a teacher and his research achievements in synthetic organic chemistry, including the Davy Medal of the Royal Society in 1945 (see *Nature*, **156**, 695; 1945). The president of the Association for 1949 is Prof. Elvin C. Stakman, professor of plant pathology in the University of Minnesota. The next meeting of the Association will be held in New York during Christmas week.

T. L. Beddoes (1803–49)

THOMAS LOVELL BEDDOES, who died by his own hand a century ago, on January 26, 1849, is an intriguing example of a medical man in whom—to use Sir Arthur MacNalty's striking phrase—the twin heritages of Apollo (medicine and poetry) were always striving for the mastery. Eldest son of the eccentric Bristol physician, Thomas Beddoes, and nephew of the novelist Maria Edgeworth, he was born at Clifton on July 20, 1803. Educated at Bath Grammar School, at Charterhouse, and at Pembroke College, Oxford, he published "The Improvisatore" while an undergraduate; but it was "The Bride's Tragedy" that won the praise of the critics in 1822. Abandoning literature for medicine, he went to Göttingen three years later, and as a medical student sat at the feet of Blumenbach, Langenbeck, and Stromeyer. After graduating M.D. at Würzburg in 1832, he practised in Germany and in Zurich. For a time he was engrossed in experimental physiology, and he translated R. D. Grainger's "Observations on . . . the Spinal Cord" into German; his translation apparently was never published. Towards the end of his life his mind became clouded, and there is some evidence to suggest that he inflicted a wound on his left leg, which became gangrenous and had to be amputated. While in hospital at Basle, he took his own life with curare, though apoplexy was recorded as the official cause of death. His macabre play, "Death's Jest-Book", was published in the following year. Despite its extravagant and unbalanced moods, Beddoes' poetry shows true lyrical greatness.

National Institute of Agricultural Engineering

THE Agricultural Machinery Development Board, which has been responsible during the past seven years for advising on research and development work on agricultural mechanization and on the management of the National Institute of Agricultural Engineering, is now being replaced by a new and independent governing body of the National Institute of Agricultural Engineering. This body will be constituted legally as a company limited by guarantee and without share capital, and will receive grant aid from the Ministry of Agriculture and the Department of Agriculture for Scotland. The headquarters station of the old Institute at Wrest Park and its Scottish station at Howden will be continued under the new organisation. The members of the governing body, consisting of a chairman and twelve members, have been appointed jointly by the two Agricultural Ministers with the advice of the Agricultural Research Council. Communications should be addressed to the Secretary, Ministry of Agriculture and Fisheries, 1–4 Cambridge Terrace, Regent's Park, London, N.W.1.

In accordance with a recommendation of the Agricultural Machinery Development Board, the Minister of Agriculture and the Secretary of State for Scotland have appointed an Agricultural Machinery Advisory Committee, which will be a permanent body and will consist of representatives of the agricultural and agricultural engineering industries and of the interested Government Departments. Communications should be sent to Col. C. K. Hamilton, Ministry of Agriculture and Fisheries, 14–21 Chester Terrace, Regent's Park, London, N.W.1.

The National Central Library

THE thirty-second annual report of the executive committee of the National Central Library, covering the year ending February 29, 1948, again refers to a considerable increase in the services of the Library to all the categories of libraries with which it is in co-operation. Issues from or through the Library during the year reached 84,889, an increase of 28·6 per cent on the previous year; of these, 8,655 were to university libraries, as against 6,073 in 1946–47, and 7,823 to the libraries of Government departments, research and industrial organisations, etc. Issues from the Scottish Central Library for Students increased from 13,690 to 15,547, and from the Irish Central Library for Students from 12,893 to 13,082. Twelve further special libraries have been added to the group of "Outlier Libraries", which now numbers 189, and 15,023 books were lent by these libraries during the year, as against 11,289 in the previous year. There are now 589 libraries co-operating in the regional systems and in the London borough libraries interlending system, and 142,832 books were lent by these libraries to other libraries in their own system during the year, as against 120,992 in 1946–47. Loans to foreign libraries during the year increased to 325, and 82 books were borrowed by British libraries from foreign sources. The Bureau of American Bibliography continues to demonstrate its value as the main source of information about American books and periodicals, and 123,270 further entries were made during the year in the main catalogues of the National Central Library, in Wales and in Scotland. Steady progress is now being made with the Union Catalogue of Russian Books and Periodicals, and the Library has also added to its activities that of a National Book Centre to coordinate the interchange and distribution of otherwise 'unwanted' publications. The report stresses the serious position caused by the continued shortage in book production, and records some increase in staff and a start on preventive repairs on the devastated portion of the building at Malet Place, London.

Spiritual Approach to Physics

UNDER the title "The Value of the Individual", Mr. F. I. G. Rawlins, in Occasional Paper No. 5 of the British Social Hygiene Council, asks physicists to look beyond their immediate pre-occupations. Physical science, he argues, arrives at a point where it can go no further; but this does not justify the assumption that there is nowhere further to go. Modern physical theory cannot (with Laplace) postulate a universe which is a self-maintaining system, about the origins or destiny of which it is superfluous to inquire. The step from physics to theology is not compulsory; but there is nothing to prevent it and a good deal to encourage it. Only when that step is taken can the universe be seen as an environment with a meaning, where human personality is able to realize itself.

Anatomy and Physiology of Acrididæ

UNDER the title of "Recent Advances in Acridology", Dr. B. P. Uvarov contributes a general survey of the literature on the anatomy and physiology of locusts and grasshoppers. It covers the period that has elapsed since the publication of the same author's book, "Locusts and Grasshoppers", in 1928. During the interval of twenty years the titles of nearly 2,500 papers, published in twelve languages, have been added to the bibliography that is kept up to date at the Anti-Locust Research Centre in London. The present survey is intended to provide a digest of all publications bearing upon anatomy and physiology. Other surveys dealing in particular with development, ecology, control, etc., will follow. The object of these digests is to further research and investigation by making the relevant literature more easily found. Particular attention has been paid to collating widely scattered data and papers that are not readily accessible. The present survey appeared, under the title given above, in the *Transactions of the Royal Entomological Society of London*, vol. 99, Part 1, pp. 1–75, 1948, and has been reprinted as "Anti-Locust Bulletin No. 1" by the Anti-Locust Research Centre, British Museum (Natural History), London, S.W.7. It is to be obtained in exchange from the Anti-Locust Centre, or may be purchased from the Royal Entomological Society, 41 Queen's Gate, London, S.W.7 (price £1 4*s*.).

Physical Society : Meeting at Edinburgh

A ONE-DAY meeting of the Physical Society will be held on February 19 at the University of Edinburgh, in the Department of Natural Philosophy. The morning session will include three papers on developments in electron focusing : T. H. Braid and H. O. W. Richardson will describe tests of a wide-angle β-particle spectrometer; R. E. Siday and D. A. Silverston will discuss tests of a prism spectrograph ; and A. N. Barker, Prof. N. Feather and H. O. W. Richardson will describe an emission microscope for photo-electron autoradiography. A paper on the use of proportional counters to investigate β-disintegration will be given by S. C. Curran, and a paper on electrons as nuclear projectiles by B. Touschek. In the afternoon session, subjects to be discussed are : a new approach to the theory of elementary particles, by Prof. M. Born and H. S. Green ; film transport in liquid helium II, by Prof. J. F. Allen ; a new photo-electric amplifier, by R. V. Jones ; and long-range molecular forces, by J. Iball.

Announcements

SIR HAROLD SPENCER JONES, Astronomer Royal, has been awarded the Catherine Wolfe Bruce Gold Medal for 1949 of the Astronomical Society of the Pacific, for distinguished services to astronomy.

PROF. P. M. S. BLACKETT, Langworthy professor of physics in the University of Manchester, has been awarded the Dalton Medal of the Manchester Literary and Philosophical Society, in recognition of his outstanding contributions to the advancement of our knowledge of physics. This Medal has been awarded on six previous occasions, as follows: Edward Schunck (1898), Sir Henry Roscoe (1900), Prof. Osborne Reynolds (1913), Sir Ernest (Lord) Rutherford (1919), Sir J. J. Thomson (1931), Sir Lawrence Bragg (1942). The presentation will take place at a conversazione with which the Society will open the new session in October 1949.

THE first award of the "Medal for Service in Agriculture and Forestry" of the Institute for International Relations in Agriculture and Forestry in Prague has been made to Prof. Doncho Kostoff, director of the Institute for Applied Biology and Organic Development at the Academy of Sciences, Sofia, and professor of plant breeding and evolution in the Faculty of Agronomy, for his monograph, "Cytogenetics of the Genus *Nicotiana* (1941/1943)", on the ground that it is the most noteworthy book in the Slavonic languages published during the last few years.

MR. J. W. TULLO has retired from the post of chief chemist to Messrs. Arthur Guinness, Son and Co., Ltd., Dublin, with whom he has been associated for the past fifty years. He has been succeeded by Mr. J. Andrews.

DR. F. A. FOX, deputy director of the British Welding Research Association, has been appointed deputy technical manager of Messrs. H. J. Enthoven and Sons, Ltd., London, E.C.3.

THE Fifty-fifth Conference of the Deutsche Gesellschaft für innere Medizin is due to take place in Wiesbaden during April 25–28, 1949. The chief themes for discussion will be: protein exchange; chemotherapy; circulation problems; and psychosomatic medicine and neuritis.

A COURSE of six lectures on "Electronics in Industry" will be given at the Electrical Engineering Department of The Polytechnic, 309 Regent Street, London, W.1, by Mr. L. I. Farran. The lectures will be given on Fridays at 6.30 p.m., commencing February 4, 1949, and the fee for the course is 10*s*.

THE University of Oxford has accepted the generous gift from the American Cyanamid Company, Stamford, Connecticut, of a Perkin Elmer infra-red spectrometer with recorder and accessories. This has been installed in the Physical Chemistry Laboratory under the supervision of Dr. H. W. Thompson, and will be used for spectroscopic investigations of a fundamental character, and particularly with regard to problems of biochemical importance. In the latter connexion it is hoped to undertake co-operative work between several of the University laboratories at Oxford.

LETTERS TO THE EDITORS

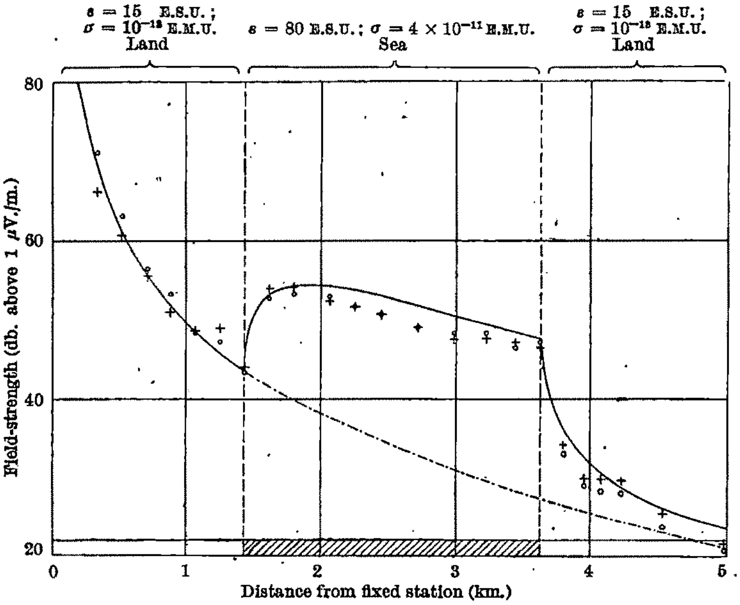
Ground-Wave Propagation Across a Land/Sea Boundary

In a paper to be published shortly[1], I have discussed the problem of ground-wave transmission across a land/sea boundary, and have predicted that under some conditions there should be a marked recovery in field-strength. On medium wave-lengths this recovery should extend to a considerable distance over sea, though, so far as I am aware, no conclusive evidence of this phenomenon has yet been published. The theory shows that the effect should not be confined to the diffraction region; but that on sufficiently short wave-lengths it should occur at distances where the Sommerfeld flat-earth analysis is valid.



———, Theoretical curve, land and sea; —·—·—, theoretical curve, land only; +, measurements at fixed station; o, measurements at mobile station. $\lambda = 3 \cdot 9$ m.; $P = 10$ watts; vertical polarization, $h_T = h_R = 0$

For vertical polarization on a wave-length of 4 metres, the recovery should be well developed when the land/sea boundary is only a kilometre from the transmitter, and the maximum increase in field-strength when both aerials are on the ground should then be of the order of 12 db. and occur at about 0·5 km. beyond the boundary. Experimentally, these conditions are favourable for the finding of a suitable site free from irregularities of terrain comparable with the wave-length, and for obtaining adequate field-strengths at the required distances with a portable transmitter. The expected increase is also greatly in excess of any likely instrumental or site errors.

Fortunately the Marconi crystal-controlled transmitter-receiver *H*.16 working on 77·575 Mc./s. (λ ≈ 3·9 m.) is ideally suited for the purpose, giving a radiation of 10 watts from a vertical half-wave dipole and permitting two-way transmission and reception with telephonic communication. An experiment has been carried out using one such set as a fixed station on the Mundon Marshes south of the Blackwater, Essex, while another was moved from it along a straight line to the shore 1·4 km. away, and then across the sea path of 2·2 km. in a motor-boat. Field-strength readings were taken at high tide at each station at intervals along the land- and sea-paths, and at a number of points on the land on the farther side.

The results are shown in the accompanying graph. On this wave-length the propagation over land is controlled mainly by the permittivity, and a value of 15 E.S.U. deduced from the shape of the initial land curve has been taken in computing the theoretical curve. The assumption that the propagation is unmodified before a boundary is effectively fulfilled, and the test confirms the prediction as regards both the extent and the position of the recovery. It also affords an interesting check of the reciprocity condition over such a composite path.

The measurements over sea were conditioned by the necessity of stopping the engine of the boat while taking a reading and the consequent drift off course. The low values may be accounted for by obstructions on the modified land path, in particular a section of sea wall lying along the path. To overcome this difficulty, a continuous recording was made at the fixed station of the signal from the mobile transmitter while the boat kept on its course at uniform speed, and the curve so obtained agrees closely with the theoretical curve over the whole of the sea path, including the initial rapid rise of field-strength.

The terrain on the farther side was less favourable for unobstructed transmission, involving the choosing of measuring sites considerably off course; but the values confirm the correspondingly rapid drop in field-strength that occurs on crossing a sea/land boundary. On this wave-length the theoretical curve would eventually settle down to the all overland curve if the sea section were somewhat farther from the transmitter.

The theory is admittedly approximate, but this confirmation at a short wave-length strongly supports the explanation I have given of these effects in terms of a redistribution of energy above the ground, whereby the height-gain relation on one side of the boundary changes to that characteristic of the section on the other side, and strengthens one's confidence in the use of the theory on medium and long waves, where the results can be of profound practical importance.

Tolerance Flux of Thermal Neutrons

THE danger of neutrons on the human body arises from two factors: the slowing down of fast neutrons and the absorption of neutrons. In the case of thermal neutrons, only absorption can take place, either in hydrogen to form a deuteron with emission of a 2·2-MeV. γ-ray, or by nitrogen-14 to form a carbon, with the emission of a 0·7-MeV. proton. In a very complete paper on the subject, Mitchell[1] finds that the ionization produced in the human body can be attributed half to the γ-rays of the latter reaction and half to the protons. This note deals only with the γ-rays from the $H(n,\gamma)D$ reaction.

Mitchell starts from the idea that the distribution of neutrons in the body is given by an exponential function, and he works out the ionization produced at the surface by γ-rays liberated in the semi-infinite medium. With a diffusion length of 2·8 cm. he finds that the maximal dose is attained with an incident flux of thermal neutrons of the order of 1,000–2,000 neutrons/cm.^{2}/sec.

It is well known that the ordinary theory of diffusion of thermal neutrons cannot be applied near a discontinuity (the surface of the body in this case), and as we expected that a purely exponential function would be invalid and could vitiate the result quite a lot, we have set up an experiment to determine the true distribution function with a thermal neutron source outside a paraffin block. This source was a 2,400-mc. radium–beryllium source in a howitzer from which neutrons are 'focused' on to a paraffin block 50 cm. away. The detectors were rhodium plates 0·05 gm./cm.^{2} irradiated for five minutes, the activities of which were measured on both sides of the detector. Those detectors were irradiated at different depths inside and outside the paraffin and in such conditions that the contribution from the different kinds of neutrons could be determined. The results are shown in Fig. 1. Curve *A* gives the total activity of the rhodium; curve *B* gives the activity when a large cadmium screen completely shielded the paraffin block; this activity being due, therefore, to the resonance neutrons and the thermal neutron by-products of the resonance slowed down to thermal energies. Curve *C*, with the rhodium plates completely shielded in a cadmium envelope, gives the distribution of resonance neutrons. Curve *E* (equals *A* – *B*) gives the distribution of thermal neutrons only.

Activities measured at the surface and outside the paraffin cannot be attributed to neutrons travelling in the direction howitzer–paraffin only, but also to neutrons scattered and diffusing back in the direction paraffin–howitzer. It can be calculated that, in our experimental arrangement, 65 per cent of outside and surface activities comes from neutrons travelling in the direction howitzer–paraffin. The neutron distribution function is then given by:

$$N = N_0 \{2{\cdot}55 \exp(-x/L) - \exp(-x/l)\},$$

for an incident flux of N_0 neutrons/cm.^{2}/sec., and with $L = 2{\cdot}1$ cm. and $l = 0{\cdot}38$ cm., equal to the thermal neutron data as given by Fermi[2].

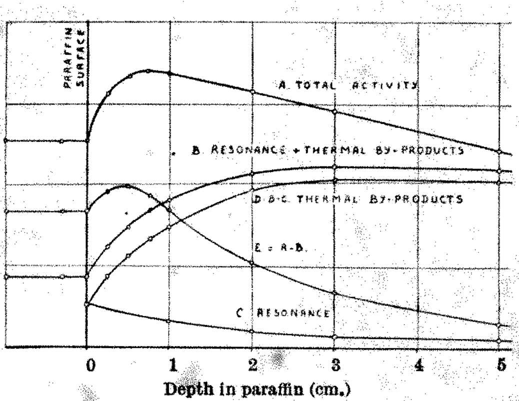

Fig. 1

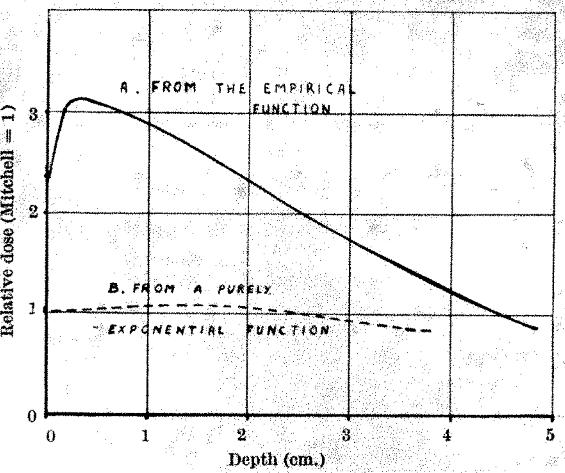

Fig. 2

This result is the outcome of, on one hand, an inside diffusion of neutrons, and, on the other, near the surface there is a leakage up to a distance which is of the order of the mean free path.

We have worked out the ionization arising from such a function at the surface as well as in depth, and extended Mitchell's calculations in depth for a purely exponential function (full details will be published elsewhere); the results are as follow:

(1) For a given incident neutron flux the surface dose is double that worked out by Mitchell (Fig. 2).

(2) The ionization dose passes through a maximum at 0·3 cm. with an intensity three times Mitchell's value.

To keep within the limits of the maximum tolerable dose, and taking into account the contribution of the $N(n,p)C$ reaction, we suggest that the maximum flux of incident neutrons should be limited to about 500 neutrons/cm.^{2}/sec.

Method of Steepest Descents in X-Ray Analysis

IN the method of steepest descents, atomic co-ordinates are derived by minimizing a function of the observed and calculated structure amplitudes. Hughes[1] minimizes $\Sigma w\,(F_0 - F_c)^2$, where the weighting factors are $w \sim 1/F_0{}^2$ when $F_0 > 4\ F_t$, and $w \sim 1/16\ F_t{}^2$ when $F_0 < 4\ F_t$; F_t is the threshold value of the measurement. As the errors do not obey Gauss' law, this formula does not give the best least-squares solution.

It was shown by Vand[2] that the formula

$$R_2 = \Sigma (F_0^2 - F_c^2)^2,$$

which is minimized by Booth[3] by the method of steepest descents, is applicable only when all the observations of the intensities of the X-ray reflexions have equal weight. A logarithmic formula

$$R_3 = \Sigma (\log I_0 - \log I_c)^2$$

was then recommended for a case where all the signs of F are known.

It can be shown both experimentally and theoretically that when the assumed co-ordinates of a structure differ greatly from the true co-ordinates, as is the rule in the initial stages of approximation, the errors $F_0 - F_c$ increase proportionately with increasing Miller indices. This effect should be taken into account when assessing their weight. When the effect of the observational errors of the intensities on weight can be neglected, a function

$$R_4 = \Sigma \frac{(F_0 - F_c)^2}{(h^2 + k^2 + l^2)}$$

should then be minimized. It is possible to derive more general formulæ which take into account the effect on weight of both Miller indices and of experimental errors simultaneously. They deserve closer study but seem to be too cumbersome for practical application. At the initial stages, R_4 should thus be preferred, until a stage is reached when no more changes of signs of F are expected, or when the discrepancies are due to experimental error in F_0 rather than to incorrect co-ordinates; then R_3 should be used. Fewer steps are then required than if R_3 were used throughout, as the correct assessment of weights has a great effect on the rapidity of convergence towards correct structure as well as on the accuracy of the final co-ordinates.

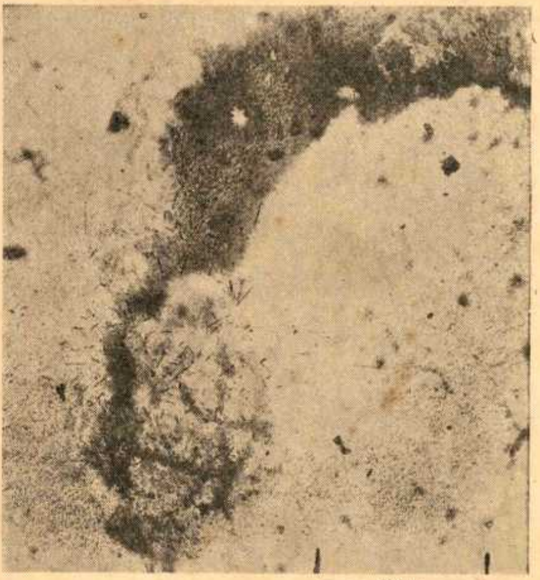
Investigation of the Distribution of the Radioactive Elements in Rocks by the Photographic Method

IN a previous communication in *Nature*[1], a brief account of the use of nuclear plates for the measurement of the total radioactive content of rocks has been given. The results showed that the distribution of the radioactive elements in rocks is not uniform, and that for some rocks quite large concentrations occur.

In order to investigate this effect more fully, a slightly different technique has been adopted. A standard microscope slide of the rock to be examined is made, but the cover glass is omitted, so that the α-rays from the rock can affect a nuclear plate placed in contact with the slide. Both slide and plate are placed in a specially constructed brass frame, in which they are held against three definite contacts, so that either slide or plate can be removed from the frame and replaced in nearly exactly the same position. Microscopic tests showed that this condition is quite accurately fulfilled. It is most convenient first to place the nuclear plate in the frame, film side up, and then put the microscope slide on top with the rock slice down. The desired exposure can then be given and the slide and plate removed for the development of the plate. The frame is now placed on the mechanical stage of a microscope and the plate replaced in it. The distribution of the α-tracks on the plate can now be correlated with the rock minerals, by replacing the rock slide on top of the plate and slightly altering the focus of the microscope. Polarized light can be used for the identification of these minerals in the usual manner. Since the rock slice has to be examined through the glass slide, only a moderate power objective can be used for the purpose. We found a Leitz No. 3*A* suitable.



It may be mentioned that both Mme. A. Hée[2] and E. E. Picciotto[3] have described similar techniques for using rock slides; but neither technique seems to be as convenient.

The first rock to be examined by this method was a Kuru granite from north of Tammerfors (Tampére), Finland. In a total area of about 8 cm.^{2} of rock examined, 45 concentrations of α-tracks were observed. Of these, 33 appeared to be due to small yellowish-brown crystals usually associated with the biotite in the section, two due to small colourless crystals, and in seven cases no obvious source in the rock structure could be detected. The accompanying photomicrograph shows the type of result obtained. The photograph has been obtained by first taking the nuclear plate image alone, then inserting the rock slide in the frame on top of the nuclear plate, refocusing the microscope, and exposing a second plate. The resulting two negatives are then combined by means of double printing, and a new negative made from this positive.

The dark material shown in the photograph is biotite, and the light background a mixture of felspar and quartz. The small yellow crystal can be seen near the lower left-hand corner. It is traversed by dark cracks. Nearly all the α-ray tracks appear to originate from this crystal. It must be remembered that a certain spread in the distribution of the tracks will occur owing to the emulsion not coinciding exactly with the radioactivity source due to the finite thickness of the rock slice and of the air film between the slice and the plate.

The total number of particles in the concentration, as shown on the original negative, is 157. Very few α-rays seem to originate definitely from either the biotite or the quartz and felspar. The nuclear plate was exposed to the rock slice for about ten days.

An attempt to identify the yellow crystals has been made by petrological methods. We would wish to thank Prof. L. B. Smyth and Mr. J. C. Brindley for their assistance in this matter. The crystals are non-pleochroic, isotropic and of high refractive index. The known constituent minerals of Kuru granite are microcline, orthoclase, quartz and biotite, with ilmenite and zircon as accessory minerals[4]. Both Prof. Smyth and Mr. Brindley consider that the crystals are probably melanite; but Brindley suggests perovskite as an alternative.

The absolute radioactivity of the crystal shown may be roughly estimated from the number of α-particles emitted. Assuming that the crystal is tabular in form, and that its thickness is the same as that of the rock slice, and that its radioactivity is due only to uranium in equilibrium with its products, we find that it must contain about 0·3 per cent of uranium by weight to emit the particles observed, if the density of the crystal is about 4 gm./c.c. This would seem to show that the crystal cannot be a pure uranium or thorium mineral. This is confirmed by the fact that about 40 per cent of the yellow crystals show no concentrations.

It may be possible to identify these crystals by further investigation, and work on this problem, and other rocks, is proceeding.

Co-ordinate Operators in Quantum Mechanics

It has been suggested that co-ordinates should be represented in the quantum theory by operators analogous to those which represent orbital angular momentum[1].

Thus, the co-ordinate x is to be replaced by $a\left(x\frac{\partial}{\partial\eta_0} - \eta_0\frac{\partial}{\partial x}\right)$, where a denotes a length and η_0 an additional co-ordinate. If η_0 be identified with the fifth co-ordinate occurring in the theory of Kaluza and Klein with the limitations, in accordance with the requirements of physics, that $\frac{\partial}{\partial x^5} = 2\pi i m_0 c/h$ and $x^5 = h/m_0 c$, where m_0 is the mass of the particle located, it follows that the x-co-ordinate operator should take the form

$$X = x - \frac{h}{m_0^2 c^2} u_x, \tag{1}$$

where[2]

$$u_x = \left(\frac{\hbar}{i}\frac{\partial}{\partial x} - \frac{e}{c}\varphi_x\right).$$

The various symbols are in common use and need not be explained in detail. The fact that the orbital angular momentum operators do not completely describe the angular momentum of a fundamental particle but require also the expression for the spin suggests that these co-ordinate operators likewise require the addition of an analogous expression. The group of angular momentum and co-ordinate operators can be regarded as forming a single tensor[3]; and from this fact it is suggested that the co-ordinate should be extended so that it takes the form

$$X = x - \frac{h}{m_0^2 c^2} u_x + \frac{i\hbar}{2m_0 c}\beta\alpha_x, \tag{2}$$

where β and α_x denote Dirac matrices.

There are similar expressions for the other co-ordinates and there is a time operator, X_4, with

$$X_4 = x_4 - \frac{h}{m_0^2 c^2} u_4 - \frac{\hbar}{2m_0 c}\beta, \tag{3}$$

where

$$x_4 = ict \text{ and } u_4 = \left(\frac{\hbar}{i}\frac{\partial}{\partial x^4} - \frac{ei}{c}\varphi\right).$$

The second terms on the right in expressions (2) and (3) mean that a minimum proper time of magnitude h/m_0c^2 is to be associated with a particle[2] of rest mass m_0. This shows that a definite extent is to be associated with a moving particle which is, however, small when the velocity of the particle is small in comparison with that of light. The last term of expression (2), like the corresponding term representing the spin, means that an intrinsic property is to be associated with the particle. Neglecting the second term, the proper values of X are $(x \pm \hbar/2m_0c)$. An interpretation of this is that, if the co-ordinate x is chosen in the usual way, the particle is described as being located at

$$(x + \hbar/2m_0c) \text{ or } (x - \hbar/2m_0c)$$

and not at any point within these limits. This indicates that a finite length $\hbar/m_0c$ is to be associated with the particle.

If X is differentiated with respect to time in accordance with the rule of quantum mechanics, it is found that

$$m_0\dot{X} = -\beta u_x - he\,(\vec{E} + \vec{H} \times \vec{\alpha})_x/m_0c^2, \tag{4}$$

where $\vec{E}$ and $\vec{H}$ denote the electric and magnetic field intensities, under the influence of which the particle is in motion. This is an interesting result, because it introduces into quantum mechanics a relation which corresponds to the familiar definition of classical mechanics, namely,

mass × velocity = momentum.

The old form is retained exactly only in the case when there are no forces, but the relation does not occur at all in the usual form of quantum mechanics.

The additional term in (4) shows how the definition is modified when the particle is accelerated, just as expression (2) shows how the co-ordinate is modified when the particle is in motion.

It also follows that, except for a small imaginary term, Dirac's equation becomes

$$\alpha_x\dot{X} + \alpha_y\dot{Y} + \alpha_z\dot{Z} - i\dot{X}_4 = c, \qquad (5)$$

which means that the velocity operator on the left of this equation has the proper value equal to the velocity of light. Finally, these expressions suggest that a solution of certain difficulties, which appear to indicate the necessity of a quantized space-time, is to be found, not in an intrinsic property of the space of physics, which possibly has no properties except those given to it by the geometer, but in an intrinsic property of matter.

Pulse Excitation of Impedance Bridges

IN the measurement of resistance in a Wheatstone bridge it is customary to use either D.C. or sinusoidal A.C. as excitation. The former is inconvenient if it is desired to use a valve amplifier as the bridge detector; the latter requires a balance of the residual quadrature component and does not indicate directly the sign of the out-of-balance condition of the bridge.

It has been found that for certain purposes the use of rectangular pulses of suitable length and recurrence frequency as excitation for a bridge offers some advantages. In the case of a resistive bridge with stray capacitance shunting one or more arms, the presence of the capacitance causes a spike with an exponential decay at the beginning and end of the pulse, which appears at the output terminals of the bridge, while the plateau which follows the spike gives a correct indication of the resistive balance condition. Investigation shows that measurements can be made in many practical cases with pulses of from 1 to 10 microsec.; while with sinusoidal excitation under similar conditions frequencies as low as 150 c./s. may be required to make the quadrature component in the bridge output negligible.

One of the most important advantages of the method is that it enables a number of bridges to be excited in sequence and their output applied to a common amplifier. This is the subject of a provisional patent application (J. G. Yates and Elliott Bros. (London), Ltd., No. 22756/47) in connexion with multi-channel resistance strain-gauge equipment. In particular, this avoids the problems of low-level electronic switching for the bridge outputs and replaces it by the easier problem of pulsing the bridge inputs.

The use of pulse excitation is not restricted to the measurement of resistance. For example, the use of pulse excitation in a capacity bridge can provide a convenient method of distinguishing between series and shunt losses in the condenser without requiring measurements at several frequencies.

Some experimental work has been done in collaboration with the Research Laboratories of Elliott Bros. (London), Ltd., and it is hoped to publish further details later.

Acclimatization to Cold in the Antarctic

DURING a year spent as medical officer to the Falkland Islands Dependencies Survey in the Antarctic at Marguerite Bay, I had the opportunity of making some observations on cold acclimatization in eleven men.

In winter and spring, the temperature varied mainly between 0° and − 35° F., though in summer temperatures just above freezing were common in the day-time. It was found that as the weather grew progressively colder with the advent of winter, little additional clothing was required. A fair amount of individual variation in clothing worn was noted, though for any given individual little increase in clothing was necessary. One man, for example, wore a string vest, long woollen underpants, an army shirt, silk scarf, socks, boots, gloves, cap with protection for the ears, thin windproof trousers and anorak (windproof upper garment with hood). This was worn for outdoor walking at temperatures down to 0° F. In colder weather later in the year, a long-sleeved sweater, warmer footgear and gloves were all that was necessary in addition. Apart from the footwear and protection for the ears, this was less than the same man was accustomed to wear in England in winter.

In winter, very exceptionally, the temperature rose from the region of − 20° F. to + 32° F. overnight, and most of the men complained of the discomfort of this relative heat wave.

Difficulties in attempting physiological research on a polar expedition are legion and account for a curtailment of the programme of investigation.

Some of the investigations were to verify interesting results reported by Frazier of the United States Antarctic Service[1], who quotes Lockhart's work. It was found, for example, that the basal metabolic rate in winter at the base in the Ross Sea was lowered paradoxically. Siple has attributed this low rate to a hibernation mechanism. It is, however, logical that in low environmental temperatures the basal metabolic rate should be raised to provide a greater output of body heat. It is a well-established fact that there is a marked rise in the metabolic rate when an animal is chilled[2,3], and this rise is attributable to an increased secretion of adrenaline with increased muscular tone and shivering[3,4]. Many observers have recorded a seasonal change, the basal metabolic rate being raised in winter and lowered in summer[5,2]. Martin[6] has observed a lowered basal metabolic rate in the tropics. Crile[7] records a raised basal metabolic rate in Eskimo, but this may be due to the specific dynamic action of a meat diet. Basal metabolic rate estimations made in winter in the Antarctic at Marguerite Bay showed an average increase of 5 per cent over a set of normal controls with the same apparatus. All estimations were made with the subject comfortably warm in bed. A likely explanation of the discrepancy between these results and those of Lockhart may be that the difference is due to a relative overheating of the United States Antarctic Service huts.

Correlated with a raised basal metabolic rate and increased adrenaline activity, one might expect a raised blood-sugar level, as is found in animal experiments[8]. Lockhart is reported to have found a raised blood-sugar level in his subjects[1]. I found an average increase of 10 mgm. per cent in the fasting blood-sugar, determined by the method of Hagedorn and Jensen, in the comfortably warm subject in winter in the Antarctic.

Frazier[1] noted an increased liability to shock following injection of a preparation of novocaine with adrenaline as a local anæsthetic. He suggested that this might be due to an increased sensitivity to adrenaline, whereby the cold-acclimatized man utilizes his adrenaline to fullest advantage. This possibility was investigated by injecting intravenously 1 c.c. of 1 in 150,000 adrenaline over a period of 90 sec. A slight increase in sensitivity as indicated by changes in the blood pressure, respiration-rate, pulse-rate and subjective sensations was noted in the cold-acclimatized man.

The capacity to work with exposed hands at low temperatures varies considerably. The physiological factor involved appears to be the reaction of the peripheral vessels to exposure to cold[9]. The reaction of the peripheral vessels to cold is influenced by the basal metabolic rate, there being less vasoconstriction if it is high[10]. A variable increase in blood pressure results from the immersion of an arm in ice-cold water for one minute (cold pressor test). This increase in blood pressure is due to stimulation of the vasomotor centre by cooled blood and by afferent impulses from the cooled skin, resulting in generalized peripheral vasoconstriction, including constriction of the digital arteries and arterioles[11]. To a lesser degree this rise in blood pressure may be due to the local effect of cold on the arterioles of the cooled hand. Fifteen men of the Falkland Islands Dependencies Survey were arbitrarily graded according to their tolerance to exposure of the hands to cold. It was observed that those who responded to the cold pressor test by a marked rise in the blood pressure suffered badly from cold hands. However, a man that suffered more than the average from cold hands did not necessarily show hyper-reaction to the cold pressor test.

In conclusion, I should like to pay a tribute to the fortitude of my comrades, who were prepared to be made the subjects of the investigations under trying conditions.

Effect of Oxygen on the Frequency of Chromosome Aberrations Produced by Alpha-Rays

In testing the hypothesis that the effect of ionizing radiations on the growth-rate of *Vicia faba* root tips is primarily due to the production of chromosome aberrations, we have shown[1] that X-irradiation under anaerobic conditions has a much reduced effect on growth, and that this is accompanied by a considerable reduction in the number of cells showing bridges or fragments at anaphase. We have now done an analogous experiment with alpha-radiation, using a modification of the method of Gray and Read[2] of immersing the roots in radon solution. Four graded doses were given to groups of eight beans in oxygen-free water, and four in water that contained 12 c.c. oxygen per litre. The mean growth of the groups of roots in the ten days following irradiation is plotted against dose in Fig. 1, together with comparable curves obtained after X-irradiation. We note that oxygen has a much greater influence on the effect of X-rays than on the effect of alpha-rays, the dose ratios for equal growth 'without/with oxygen' being $\sim 2{\cdot}5$ and $\sim 1{\cdot}3$ respectively.

For the cytological study, two radon seeds of equal strength were selected, and the conditions of the two irradiations were kept alike, except that the water contained 12 c.c. oxygen per litre in one case and none in the other. The application of a few small corrections resulted in estimates of the doses of 7·66 energy units[3] with oxygen, and 8·02 energy units without oxygen. Root tips were fixed at intervals up to 72 hours after treatment. Feulgen squashes were made, and a hundred anaphases were examined in each to determine the percentage that showed bridges or fragments. At six times of graph 1 and seven of graph 2 the data were obtained from two root tips, and, at the remainder, from one. Except in one case the two data have been combined, as their mean was within the standard deviation of each. The results, Fig. 2, suggest that the yield of aberra-

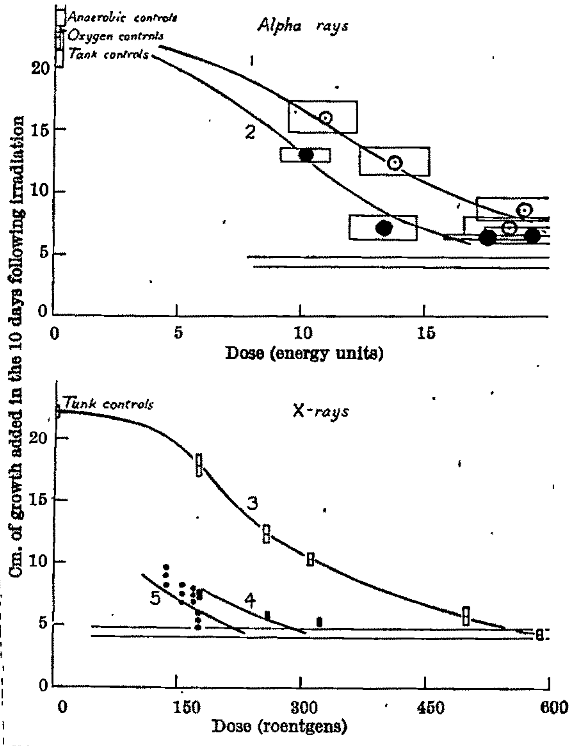

Fig. 1. Each point is the mean growth in ten days subsequent to irradiation of groups of 6 to 9 bean roots. The standard deviation is marked by a vertical line. 10 per cent of the alpha-ray dose has been considered the equivalent of a standard deviation. 1, Alpha-rays, zero oxygen concentration; 2, alpha-rays, 12 c.c. oxygen per litre; 3, X-rays, zero oxygen in the water; 4, X-rays, 6 c.c. oxygen per litre; 5, X-rays, 12 c.c. oxygen per litre. The horizontal lines at growths of 4 and 4·8 cm. illustrate the mean growth in length, with standard deviation, of a group of roots which all die as a result of irradiation, and represents the extension due to the elongation of existing cells, a process insensitive to radiation. All the curves, therefore, terminate in this zone

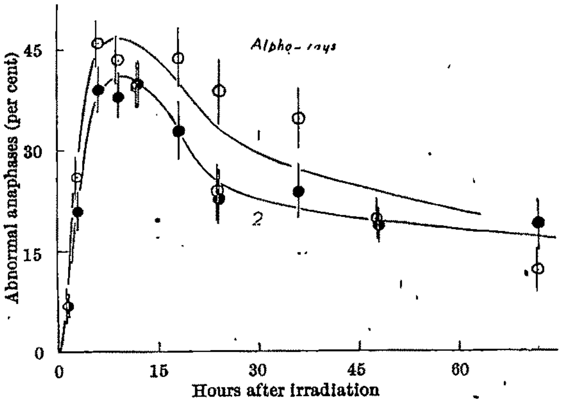

Fig. 2. 1, Dose, 7·7 energy units; oxygen content 12 c.c. per litre. 2, Dose, 8·0 energy units; oxygen content zero

tions when oxygen is present is somewhat greater than in its absence, but there can be no doubt that the increase due to oxygen is far less than that shown when X-rays are used (ref. 1, Fig. 2).

As before, we find a close correlation between the effects of different treatments on growth-rate and on the number of chromosome aberrations produced.

The effects of oxygen on the production of chromosome aberrations in *Vicia* by X- and alpha-radiations parallel its effects in promoting the decomposition of water by these radiations. Experiments summarized by Allsopp[4] and Lea[5] support the conclusion that pure oxygen-free water is not decomposed by X-rays, but if there is dissolved oxygen then hydrogen peroxide is produced. Alpha-rays, on the other hand, can produce hydrogen peroxide whether oxygen be present or not. Our results, therefore, suggest that hydrogen peroxide has some influence on the processes involved in chromosome structural change. We regard Mottram's[6] observation that cyanide increases the sensitivity of roots to X-rays as supporting this conclusion, since the inhibition of catalase or peroxidase may be expected to increase the effective concentration of hydrogen peroxide. It is, of course, impossible at this stage to decide whether hydrogen peroxide is the agent effecting chromosome breakage, or whether it merely influences the behaviour of broken chromosomes. The evidence of Kotval and Gray[7] that there is some spread of the effect of an alpha-particle may be held to favour the former alternative. On the other hand, we have evidence that oxygen increases the inhibition of mitosis by X-rays, and that while it increases the stickiness produced by X-rays it does not seem to affect the stickiness produced by alpha-rays, facts which might be held to favour the second alternative.

Total X-Irradiation of Rats under Urethane Anæsthesia

The therapeutic use of urethane in human leukæmias, discovered by Paterson, Ap Thomas, Haddow and Watkinson[1], has led many authors to study the action of urethane in comparison with that of X-rays. However, treatment of patients by X-rays *during* the period of urethane administration was mentioned for the first time by Vannotti[2] in two cases of myeloid leukæmia. More recently, Dustin and Simon[3] have obtained promising results in chronic myelogenous leukæmia by splenic irradiation concurrently with administration of urethane (2–3 gm. a day).

In 1925, Hawkins and Murphy[4] pointed out, in a footnote to their study of ethylurethane anæsthesia and acid-base equilibrium of the blood, that "rats under urethane anæsthesia irradiated by a dose of X-rays far below the lethal dose, died invariably between the 7th and 14th day". No technical detail was given, and these experiments do not seem to have been repeated. Recently, Paterson[5] found no cumulative action of urethane and X-rays either on fern spores or on fibroblast cultures.

In view of the potential clinical importance of the simultaneous application of urethane and X-rays, an attempt has been made to confirm the observations of Hawkins and Murphy.

To compare results of different experiments, the dose of radiation killing 50 per cent of the animals within 14 days (L.D. 50/14 days) was chosen in preference to that required to kill all the animals within the same time (absolute lethal dose, Ellinger[6]).

The rats used were of an albino strain and of weights ranging from 90 gm. to 140 gm. Each experiment was conducted with groups being irradiated under the same conditions. Rats for irradiation were placed in cardboard boxes divided into separate compartments. Preliminary experiments had shown an L.D. 50/14 days of 600 r., although it is evident that this value may vary with the strain, the age and the weight of the animals as well as with the conditions of the experiment. Following treatment, records were kept of the body-weight.

Irradiation, measured with an ionometer, was performed as follows: (1) rats irradiated with 500 r.: 200 kV. 8 mA.; focus-target, 60 cm.; filtration, 0·5 mm. copper + 1 mm. aluminium (rate, 29 r./min.); (2) rats irradiated with 600 r.: 200 kV. 10 mA.; focus-target, 80 cm.; filtration, 0·5 mm. copper + 1 mm. aluminium (rate, 20 r./min.). Rats in each group received the same dose.

Urethane was injected intraperitoneally, as in Hawkins and Murphy's report, using 1 c.c. of 10 per cent urethane solution per 100 gm. body-weight. Under these conditions, anæsthesia occurs very promptly. Irradiation of anæsthetized animals was made half an hour after urethane injection at the same time as the controls. Each rat was later kept in a separate cage.

Irradiation with 600 r. proved to be the L.D. 50/14 days for the control series.

Irradiation with a dose of 500 r. killed about 20 per cent of the animals within 14 days, both controls and anæsthetized. Thus, it could scarcely be said that a dose of X-rays far below the lethal dose kills all the rats under urethane anæsthesia, as 500 r. is within 20 per cent of the L.D. 50/14 days.

Irradiation with the L.D. 50 (600 r.), on the contrary, demonstrated a notable difference between the control and anæsthetized animals: while 50 per cent of the controls died within 14 days, 90 per cent of the anæsthetized rats died within the same period. Hence, if there is any lethal cumulative effect or sensitization resulting from association of urethane anæsthesia with whole-body irradiation, it can only be observed within a range close to the L.D. 50/14 days. If, however, Hawkins and Murphy's test of mortality was the absolute lethal dose, the cumulative effect would have seemed important, since a dose of X-rays, two-thirds of the absolute lethal dose, would have produced in urethanized animals about the same effect as the absolute lethal dose in control rats.

To determine whether urethane anæsthesia sensitizes to X-rays, or acts cumulatively, experiments should be carried out by administering urethane after irradiation. Further research is proceeding along these lines.

A Contracture in Isolated Mammalian Muscle

Recently, Goffart and Brown[1] have shown that the effectiveness of adrenaline in increasing the twitch tension of the isolated rat's diaphragm preparation is inversely proportional to the amount of potassium ion in the bath. In continuation of these experiments, I have been studying the responses of the rat's diaphragm preparation immersed in potassium-free Tyrode's solution.

Administration of adrenaline ($1:10^5$–$1:10^6$) causes the usual increase in twitch tension, but this may be followed by a progressive delay in relaxation. The delayed relaxation of the muscle shows itself in the first place by a reduction of the 'overthrow' of the light spring-loaded lever used for recording. The 'overthrow' is usually increased during the potentiation of twitch tension, which is the first effect of adrenaline. If the fluid in the bath is left unchanged, the 'overthrow' is seen gradually to decline, until, some 20 min. after giving adrenaline, relaxation is clearly diphasic, a rapid initial phase being followed by a slow return of the lever to the base line. The first phase of relaxation then becomes shorter, and the slow phase starts nearer the peak of the contraction curve. The delayed relaxation is not accompanied by conducted repetitive action potentials, and appears, therefore, to be of the nature of a true contracture.

The only observed changes in action potential were similar to those described by Brown, Bülbring and Burns[2]. The contracture can be produced in fully curarized muscle stimulated directly and appears, therefore, to be of purely muscular origin. It is increased by increasing the calcium chloride content of the bath fluid from the normal 0·02 per cent to 0·06 per cent, and is at first increased and then suppressed by addition of potassium chloride to give a final concentration of 0·04 per cent. Although the contracture can be generally produced by addition of adrenaline, the latter is not invariably necessary, since prolonged stimulation of a preparation in potassium-free Tyrode's solution may produce it; adrenaline appears to accelerate the process. The contracture is increased by using lower frequencies of stimulation (< 1 in 10 sec.) and may be suppressed by increasing the frequency of stimulation from 1 in 10 sec. to 1 per sec. High concentrations of atropine and quinine ($1 : 10^4$) eventually suppress the contracture, and it is also very sensitive to changes in temperature: cooling by 0·5° C. may increase it, and warming the preparation by 1° C. may remove it.

Utilization of Folic Acid Conjugate in Man

Heinle and Welch[1] have already made some observations on the utilization of folic acid conjugate. They did not observe formation of free folic acid from pteroyl-hepta-glutamic acid after incubation of the latter product with normal gastric or duodenal juice.

We have repeated this investigation and have found that the hepta conjugate is altered by normal gastric juice, although no free folic acid could be demonstrated (Buyze and Engel[2]).

If the incubation product of gastric juice on folic acid conjugate from yeast is incubated with rat liver conjugase prepared according to Mims, Totter and Day[3], no free folic acid was formed. This was not due to conjugase inhibitors present in gastric juice or yeast extract, as has been demonstrated[2]. This alteration of folic acid hepta conjugate into another 'conjugate' by normal gastric juice was not brought about by gastric juice of pernicious anæmia patients. The gastric juice of a sprue patient behaved like a normal human gastric juice in this respect. Normal duodenal juice was not active against pteroyl-hepta-glutamic acid or the conjugate formed by the gastric juice.

Olson, Fager, Burris and Elvehjem[4] have demonstrated that pteroyl-glutamic acid was present in rat liver not only in the form of its hepta conjugate but also in another conjugated form. It was possible to obtain free pteroyl-glutamic acid from the latter by incubation with liver homogenate. It appeared that from the gastric juice incubation product also free folic acid could be obtained by incubation with rat liver homogenate at *p*H 7.

Antigenic Activity of Myosin and Actin

To our knowledge, the immunological behaviour of contractile muscle proteins has not been investigated. We immunized three rabbits and three dogs with rabbit's myosin prepared by the method of Szent-Györgyi[1]. We used intraperitoneal injections of 2·5 per cent myosin solution, the myosin being dissolved in 0·4 *M* potassium chloride. The animals received 0·5 gm. of myosin in increasing doses during seventeen days; they lost no weight during the treatment. With these antisera, precipitation tests were performed with the following antigens: rabbit's myosin, *F*-actin, *G*-actin, *F*-actomyosin and normal rabbit serum. The same tests carried out before treatment with normal sera of animals afterwards immunized served as controls. The results are seen in Table 1.

Table 1

	Myosin	Rabbits' *F*-actin	*G*-actin	*F*-actomyosin	Serum protein
Rabbit 1	—	—	—	—	—
„ 2	—	—	—	—	—
„ 3	—	—	—	—	—
Dog 1	+ + + 1: 500	—	—	+ +1 : 125	—
„ 2	± 1: 4000 + 1: 2000 + + 1: 1000 + + + 1: 500	—	—	+ +1 : 1000	—
„ 3	—	—	—	—	—

Rabbits' myosin injected into rabbits intraperitoneally did not incite antibody formation; this indicates that the presence of myosin in the blood of the same species does not lead to the production of *iso*antibodies. We succeeded in obtaining myosin antisera from two of the immunized dogs. The immune sera did not react with *F*- and *G*-actin; this indicates that the myosin prepared by the method of Szent-Györgyi is free from actin. *F*-actomyosin reacts with the antisera for myosin; this may be explained either by the presence of free polar groups of the myosin molecule in the actomyosin, or by the presence of free unchanged myosin molecules in the antigen solution after the linkage between actin and myosin. The probability of the latter explanation seems to be corroborated by the lower precipitation titre of myosin antisera with actomyosin and by the circumstance that—according to Szent-Györgyi—actomyosin does not represent a stoichiometrically definable compound.

In further experiments, we used *G*-actin from rabbits' muscle prepared by the method of Straub[1]. Three rabbits and three dogs were immunized with 0·3–0·6 per cent water solutions of *G*-actin. The animals received intraperitoneally 120 mgm. actin in increasing doses during seventeen days. Three weeks later, precipitation tests were made using the same antigens as in the previous experiment.

Table 2

Rabbit	Myosin	*F*-actin	Rabbits' *G*-actin	*F*-actomyosin	Serum protein
1	—	—	—	—	—
2	—	+1 : 500 + + +1 : 250	+1 : 500 + + +1 : 250	+1 : 500 + + +1 : 250	—
3	—	+1 : 2000	+1 : 2000	+1 : 1000	—
Dog					
1	—	+1 : 2000	+1 : 2000	+1 : 2000	—
2	—	—	—	—	—
3	—	+ + +1 : 250	+ + +1 : 250	+ + +1 : 250	—

The sera of two immunized rabbits precipitated rabbits' actomyosin with a relatively high titre. It follows that rabbits' actin administered to rabbits parenterally incites antibody formation, that is to say, it represents an *iso*antigenic, organ-specific protein. The antisera of dogs and rabbits reacted equally with *F*-actin; this indicates that the activation of actin did not result in any changes in the antigenic (chemical) structure of *G*-actin. Antisera for myosin and actin behave similarly towards actomyosin.

Determination of Adrenaline in Blood Plasma by the Fluorescence Method

Among chemical methods for determining adrenaline in blood the fluorescence method seems superior[1-6]. It has been used in two basically different versions: either blood plasma[3,4] or a dialysate of hæmolysed blood[1,2,5,6] has been analysed. It is noteworthy that the first method gives much higher values than the second.

Theoretical objections may be raised against adrenaline determinations on dialysates of hæmolysed blood, since the supposed state of equilibrium on both sides of the membrane after four hours of dialysis is assumed, based on the fact that the adrenaline concentration in the outer liquid attains its maximum after four hours. As adrenaline cannot be determined in hæmolysed blood, simultaneous control determinations in the impermeate are impossible. Also the eventuality that the adrenaline might be bound to the protein and, therefore, hindered from dialysing through the membrane has been overlooked. Keeping these factors in mind, we have found occasion to compare the two methods more closely.

In so doing we used a modification of Lehmann's and Michaelis' method[3,7], which has the essential advantage that, by using a Beckmann spectrophotometer with an accessory fluorescence set, readings are easier to take and less subjective. This method yielded reproducible results; determinations on plasma with known adrenaline contents and on plasma with a known quantity of adrenaline added gave results closely corresponding to calculated ones.

Determinations were made on plasma and blood by the method of dialysis, and directly on plasma. This showed that the dialysis method yields values in the dialysate which closely correspond to those obtained by other authors in tests on hæmolysed blood, namely, approximately 0·07 μgm./ml. A small decrease was noted in the plasma impermeate which, in this case, may be analysed in parallel to the dialysate. The concentration was, however, of the same magnitude as that found in analysing untreated plasma, namely, 1–3 μgm./ml. Therefore only some few per cent of the adrenaline had passed through the membrane. The same low values in the dialysate were obtained in testing hæmolysed blood. Analogous tests on aqueous solutions of adrenaline showed the outer and inner liquids to be in equilibrium after four hours.

This observation leads us to conclude that the two modifications of the fluorescence method give incompatible results. In one case, free dialysable adrenaline is determined, whereas in the other total adrenaline contents, including both free and protein-bound adrenaline. The existence of both these forms of adrenaline is probably of the greatest importance for the biological activity of this substance in the tissues.

A more comprehensive report will be published in due course.

Bilateral Asymmetry Shown by the Metachronal Waves in Protochordate Gill Slits

MULLER[1] stated that metachronal waves travelled round the gill slits of *Amphioxus* "am vordern Rande aufwarts, am hinten abwarts"; but he figured them moving in the opposite direction on the left side of the pharynx. Franz[2] did not clear up the contradiction, though he, too, noted and figured the metachronal waves. Fedele[3], in a figure of the gonozoid of *Doliolum mulleri*, indicated by arrows the movement of the metachronal waves around the stigmata. The movement appeared anti-clockwise on both sides, seen from outside the pharynx. McGinitie[4], examining the pharynx of *Ascidia californica* through the transparent test, also noted that the motion was anticlockwise. Since he did not state from which side of the animal this observation was made, it might be inferred that the direction appeared the same from both sides; but McGinitie did not specifically affirm this nor did he direct attention to the functional asymmetry implied. If the animal were bilaterally symmetrical in this respect, the movement would appear anticlockwise from one side but clockwise from the other, like the wheels of a car in motion.

During work on the development of *Saccoglossus*, carried out in collaboration with Mr. C. Burden Jones, University College of North Wales, Bangor, it was noted that the metachronal waves in the primary gill pores moved anticlockwise on both sides, as seen from the exterior. In adult *Saccoglossus*, as in *Amphioxus*, the shape of the gill slits is greatly modified by the down-growth of the tongue bars, yet the movement of the waves is uninterrupted and their direction is the same as in the larva. It was observed by opening the pharynx in the mid-ventral line, viewing the gill slits from within and waiting for the cilia to resume activity. From this point of view the motion appeared clockwise. The pharynx in young specimens of *Ciona intestinalis* and *Ascidia aspersa* was examined through the transparent test. The waves which moved around each stigma appeared anticlockwise on both sides of these animals. Mr. D. P. Wilson kindly informed us that in *Amphioxus* the direction of the metachronal waves is clearly anticlockwise on both sides, seen through the transparent body wall. Muller's figure is therefore correct, but his statement, quoted above, applies only to the gill slits of the right side.

Hitherto, *Amphioxus* has provided the only strong link between the Hemichordata and Urochordata in respect of the structure of the pharynx, so it is noteworthy to find, in the activity of the lateral cilia, a point of detail common to all three Protochordate groups. A similar asymmetry is shown by the velar cilia in Gastropod larvæ having a bilobed velum, but this is only to be expected, for the lobes are the parts of a single velum around which the waves travel uninterruptedly. There is no reason to believe that gill slits have been derived from unpaired structures, and the significance of the asymmetry in Protochordates is much more obscure.

According to Fedele[3], the activity of the lateral cilia in *Doliolum* imparts a rotation to the current of water which passes through each stigma. This causes the column of water within the pharynx to rotate, forming a vortex which plays a part in directing into the narrow entrance to the œsophagus the mucous strings by which the food is collected. It appears, therefore, that in this form the asymmetry in the gill slits may indirectly assist the feeding mechanism. In *Salpa*, however, the numerous feeding strings are sucked into a similar vortex produced by the ciliary activity of the œsophagus and intestine[5]. To judge from Fedele's account, this mechanism, which is essentially the same as that in *Doliolum*, operates in *Salpa* without the aid of the functional asymmetry under review here. It is therefore doubtful whether this asymmetry is of great importance even in *Doliolum*. Outside the Thaliacea, it appears to be entirely non-adaptive, yet its general occurrence suggests that it was present in ancestral Chordates. The following considerations suggest a possible direction in which the cause of its origin might be sought.

In the larva of *Saccoglossus* and in the *Tornaria* there is a belt of large cilia, the telotroch, encircling the body immediately behind the primary gill slits. Well-marked metachronal waves travel around it anticlockwise, as seen from the animal pole[6], that is, up the left side of the body and down the right. Soon after the first gill slits appear, the telotroch starts to regress, but in *Ptychodera bahamensis* it can be distinguished for some time after metamorphosis, and it is carried backwards as the trunk elongates so that each of the early gill slits appears in turn immediately in front of it[7]. The first gill slits, therefore, develop in the immediate proximity of a strong ciliary field which is continuously active. It is possible that the bilateral asymmetry in the ciliary mechanism of the gill slits is associated in some way with that of the telotroch. As they develop, the posterior borders of the gill slits immediately adjoin the telotroch. The metachronal waves on these posterior borders come to move in the same direction as did those of the telotroch, upwards on the left side, downwards on the right.

The activity of the telotroch causes the larvæ of *Enteropneusta* to rotate about the longitudinal axis in a clockwise direction viewed from the animal pole[6]. The rotation and the movement of the metachronal waves are associated phenomena. An exactly similar rotation has been observed in the early larva of *Amphioxus*[8,9], a fact which suggests the existence there of a similarly orientated ciliary field. This, in turn, suggests that such a field may have been present in the larvæ of ancestral Chordates.

A Simple Medium for Cultivation of *V. choleræ*

The nutritional requirements of *V. choleræ* have been studied with the object of developing a simple medium capable of giving a massive growth of the organism which could be used directly as a vaccine. The investigations were on the lines followed by Linton and Jennings[1-3]. It was found possible to obtain concentrations as high as 14,000 million organisms per ml. of *Inaba* or *Ogawa* strains of *V. choleræ* maintained at this Institute by the following method.

A 2-litre flask containing the following was autoclaved: sodium chloride, 8 gm.; potassium chloride, 0·2 gm.; calcium chloride, 0·4 gm.; magnesium chloride, 0·2 gm.; sodium dihydrogen phosphate, 0·06 gm.; ammonium sulphate, 5 gm.; magnesium sulphate, 0·1 gm.; and distilled water, 1,000 ml. To this was added 30 ml. of 33⅓ per cent glucose solution and 27·5 ml. of 0·1 per cent *l*-cystine. The latter was made by dissolving 100 mgm. of *l*-cystine in 30 ml. of $N/10$ sodium hydroxide, which was then made up to 100 ml. with distilled water. To the mixture was added 5 ml. of a 5 per cent solution of 'Marmite' paste in distilled water. The solutions of glucose, *l*-cystine and 'Marmite' were sterilized by steaming. 11 gm. of sodium bicarbonate powder, sterilized by autoclaving, was added to the mixture and shaken until all the bicarbonate dissolved. The final *p*H of the medium was 8·8.

About 60 ml. of the medium was removed for purposes of subpassage, etc., and the remaining 1,000 ml. inoculated with 10,000 million organisms of *V. choleræ*; either *Inaba* or *Ogawa* strains or a mixture of 5,000 million organisms of each were used. The best results were obtained with an inoculum of an eight to twelve hours culture of the organism which had undergone at least six serial passages in the above medium and become adapted to it. The flask was incubated at 37° C. At the end of 10, 16 and 24 hr., 12 ml. of glucose solution and 9 gm. of sterile sodium bicarbonate were added to the cultures, shaken well and returned to the incubator. With the above method it was possible to obtain concentrations of 12,000–14,000 million organisms per ml. of both the strains at the end of 30 hours incubation.

The ammonium sulphate in the medium served as a buffer. Without the addition of ammonium sulphate, growth started earlier but ceased at the end of 10 hours when the *p*H reached 6·7. By periodic neutralization of the medium with sodium bicarbonate, it was possible to maintain the *p*H in the vicinity of 8, with a marked increase in the growth of vibrios.

The salts used in the medium had a beneficial effect on the growth of *V. choleræ*. Of the several amino-acids tried, *l*-cystine had a beneficial effect. Addition of tryptophan was necessary for the cultures to give the cholera red reaction. 'Marmite' paste had a marked growth-promoting effect on the organism. Substitution of 'Marmite' with thiamine hydrochloride, nicotinic acid, pyridoxine hydrochloride, calcium pantothenate, riboflavin, biotin and yeast nucleic acid, singly or in combination, did not give equally good results.

Cultures need not be shaken periodically except while adding extra quantities of glucose and sodium bicarbonate. Periodic shaking of the cultures or bubbling of air or oxygen through them did not improve the growth. Bubbling of carbon dioxide had a deleterious effect on the cultures.

Concentrations of 12,000–14,000 million organisms per ml. were obtained when the organism was grown in 3-litre quantities in a 4-litre flask.

The above medium, without the addition of ammonium sulphate and magnesium sulphate and adjusted to *p*H 8·8 with sodium bicarbonate, was found to be better than Dunham's peptone water for the isolation of *V. choleræ*.

Cultures containing 14,000 million organisms per ml. were rendered sterile by the addition of 0·5 per cent phenol and incubation at 37° C. for 24 hours. The antigenic value of these cultures is under investigation.

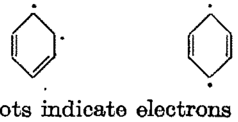
Reactive Structures of Hydrocarbons and Catalytic Hydrogenation

A carbon atom in its ground-state has the structure $1s^2 2s^2 2p^2$, ^3P. In such a state, the spins of the *p* electrons are coupled to unity. Penney[1] has shown that in order to obtain a divalent carbon atom, that is, one in which the spins are free, a mixture of the ^1D and ^3P states in the ratio 1 : 3 must be considered. The energy of attaining such a structure is the promotional energy. Such a structure has no independent existence, but arises from a perturbation of the carbon atom by the atom with which it is going to form a bond.

The concept may be extended to ethylene and to conjugated and aromatic systems. A reactive structure may be thought of as having two electrons with free spin at the given positions. Thus, for benzene there are two possibilities:



where the dots indicate electrons the spins of which are essentially free. The reaction structure may be thought of as a combination of singlet and triplet in the ratio 1 : 3. For any position in any molecule, that is, for any reactive structure, the energy may then be written in the form:

$$E_r = (1{\cdot}5 + n_r - n_p)\alpha, \qquad (1)$$

where α is the valence-bond exchange integral and n_r and n_p are the coefficients of α in the expression for the resonance energies of the reactant and product molecules respectively.

It would appear likely that the concept of the reactive structure might prove useful in a discussion of homolytic bicentric reactions between a series of molecules and a common reaction partner. Catalytic hydrogenation would appear to be a reasonable reaction to choose "since all the observed facts are in harmony with the conception that the catalyst in hydrogenation combines with both the hydrogen acceptor and the hydrogen"[2].

The main feature of catalytic hydrogenation may be explained on the basis of the reactive structure. The ease of hydrogenation of an isolated double bond follows at once from the low E_r for such a reaction ($n_r = n_p = 0$). On the other hand, the resistance of benzene to catalytic hydrogenation can be explained in terms of the large value of E_r, due to n_r being much greater than n_p. However, in the event of two atoms of hydrogen being added, E_r for the further addition becomes considerably decreased, and this is evidenced by the tendency for complete reduction of a benzene ring in a polycyclic compound. In general, the difficulty of reduction of conjugated systems relative to an isolated double bond is explicable in terms of n_r being greater than n_p, leading to large values of E_r. Another example of the use of the concept is afforded by the relative indifference to the position of addition in the case of butadiene, for in this case E_r is the same for both $CH_2{=}CH{-}CH{-}CH_2$ and $CH_2{-}CH{=}CH{-}CH_2$.

The concept of the reactive structure lends theoretical support to the assumption used by Pauling and Sherman[3] in their discussion of conjugated systems. These authors assumed that the product will be formed the more readily the greater its thermodynamic stability. This hypothesis was used in a discussion of the position of hydrogenation within a given molecule, and follows directly from (1). The purpose of the present note is to provide a basis for a discussion of relative ease of hydrogenation.

A fuller discussion of this subject will be presented elsewhere in due course.

Estimation of Polymer Distribution on the Basis of Differences between the Average Molecular Weights of Different Order

IT is well known that the magnitude of the difference between the number and weight average molecular weight (M_n and M_w) in a polymer affords an indication of the degree of polydispersity. In order to obtain a numerical measure of the spread of molecular weights, and to reconstruct the distribution, the assumption is often made—though admissible only under certain conditions—that the distribution function is that of the log normal law[1-3], where the ratio between averages (the rth roots of the rth moments about zero) of successive order is an exponential function of the logarithm of the geometric standard deviation, which is equal to the standard deviation of the logarithmic distribution.

It has, however, so far escaped observation that from a knowledge of M_n and M_w the standard deviation of the molecular weights can be calculated directly and exactly without any assumption whatsoever about the distribution law.

Defining M_n as

$$M_n = \frac{\Sigma M_i n_i}{\Sigma n_i},$$

as obtained, for example, by the osmotic pressure method; and M_w as

$$M_w = \frac{\Sigma M_i g_i}{\Sigma g_i} = \frac{\Sigma M_i^2 n_i}{\Sigma M_i n_i},$$

as obtained, for example, by the light scattering method, where n_i, g_i are the frequencies and weights, respectively, of the molecular species M_i, we form the product

$$M_n M_w = \frac{\Sigma M_i n_i}{\Sigma n_i} \times \frac{\Sigma M_i^2 n_i}{\Sigma M_i n_i} = \frac{\Sigma M_i^2 n_i}{\Sigma n_i}.$$

Since

$$\sigma_n = \sqrt{\frac{\Sigma M_i^2 n_i}{\Sigma n_i} - \left(\frac{\Sigma M_i n_i}{\Sigma n_i}\right)^2},$$

we have at once for the standard deviation of the number distribution:

$$\sigma_n = \sqrt{M_n M_w - M_n^2}.$$

Similarly, if in addition to M_w, M_z is defined by

$$M_z = \frac{\Sigma M_i^2 g_i}{\Sigma M_i g_i} = \frac{\Sigma M_i^3 n_i}{\Sigma M_i^2 n_i},$$

as obtained, for example, by the sedimentation equilibrium method (if the concentration gradient is observed by the refractive index method), we form again the product

$$M_w M_z = \frac{\Sigma M_i g_i}{\Sigma g_i} \times \frac{\Sigma M_i^2 g_i}{\Sigma M_i g_i} = \frac{\Sigma M_i^2 g_i}{\Sigma g_i},$$

and have for the standard deviation of the weight distribution

$$\sigma_g = \sqrt{M_w M_z - M_w^2}.$$

Knowing the mean and the standard deviation in either number or weight distribution of molecular weights, we are in a position to obtain a conservative estimate of the whole distribution by using the so-called Tchebycheff inequality[4]. According to that relation, the proportion of molecules with molecular weights differing from the mean weight by an amount not exceeding ± t times the standard deviation is, at least, $1 - 1/t^2$. By substituting arbitrary values for t ($5 > t > 1$), and subtracting the proportion for the smaller t from that for the next higher one, we obtain the relative frequencies (number distribution) or the weight fractions (weight distribution) of the molecular weight species at the specified distances from the mean.

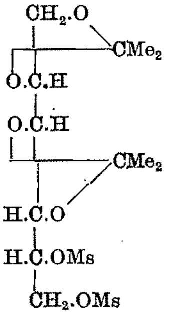
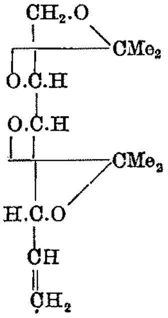
Reaction of Vicinal Dimesyl Compounds with Sodium Iodide, and its Application to the Interconversion of Hexitols

THE recent paper of Karrer and Davis[1] prompts us to report some work of a similar nature, on which we have been recently engaged.

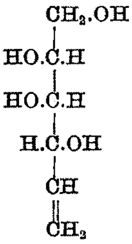
Previous investigators[2-4] have shown that treatment of a compound containing two or more vicinal tosyloxy groups, with sodium iodide, leads to the elimination of all these groups, whether primary or secondary, with formation of an unsaturated compound, and the liberation of iodine. We have been using this type of reaction mainly for the preparation of intermediates for the synthesis of polyhydroxy dithiols (cf. Evans and Owen[5]), and have found that it is equally applicable to mesyl (methanesulphonyl) compounds.



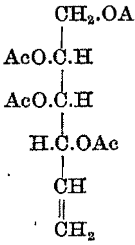
I



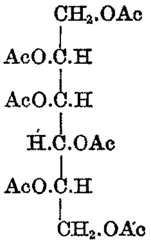
II



III



IV



V

(Ms = $CH_3.SO_2$—)

Treatment of 5 : 6-dimesyl 1 : 2-3 : 4-diacetone D-mannitol (I) (m.p. 117·5–120°, $[\alpha]_D^{20°}$ + 25·1° ; all rotations in this communication were determined in chloroform solution unless otherwise stated) with sodium iodide in acetone solution at 100° gave a 65·5 per cent yield of 1 : 2-3 : 4-diacetone 5 : 6-mannitoleen (II), a colourless liquid, b.p. 41°/0·1 mm., $n_D^{23°}$ 1·4401, $[\alpha]_D^{21°}$ − 5·49° (found : C, 63·4 ; H, 8·6. $C_{12}H_{20}O_4$ requires C, 63·1 ; H, 8·8 per cent), together with a small amount of 5 : 6-mannitoleen (III), (Karrer's D-*arabo*-3 : 4 : 5 : 6-tetrahydroxyhex-1-ene), m.p. 147–149°, $[\alpha]_D^{20°}$ + 30·9° (water). Hydrolysis of the diacetone compound in the usual way gave a 69 per cent yield of 5 : 6-mannitoleen, [tetra-acetate (IV) m.p. 80–81°, $[\alpha]_D^{21.5°}$ + 49·4°]. Karrer and Davis[1], who employed 5 : 6-ditosyl 1 : 2-3 : 4-diacetone mannitol as starting material in a similar reaction, failed to isolate diacetone mannitoleen, and obtained only mannitoleen in 26 per cent yield.

Similar treatment of 5 : 6-dimesyl 1 : 3-2 : 4-diethylidene sorbitol with sodium iodide gave a theoretical yield of 1 : 3-2 : 4-diethylidene 5 : 6-sorbitoleen, m.p. 122–123°, $[\alpha]_D^{21°}$ − 21·6° (found : C, 60·4 ; H, 7·9. $C_{10}H_{16}O_4$ requires C, 60·1 ; H, 8·1 per cent), acid hydrolysis of which afforded 5 : 6-sorbitoleen (97 per cent yield), a colourless syrup, b.p. 100–130° (bath)/10^{-4} mm., $n_D^{15°}$ 1·5068, $[\alpha]_D^{19°}$ + 19·8° (water) (found : C, 48·5 ; H, 8·3. $C_6H_{12}O_4$ requires C, 48·6 ; H, 8·2 per cent) (tetra-acetate, m.p. 57–58·5°, $[\alpha]_D^{22°}$ − 13·6°). 5 : 6-Ditosyl 1 : 3-2 : 4-diethylidene sorbitol gave the same products, though in poorer yield.

Incidental to the main work, the following new method for the interconversion of hexitols has been evolved. Treatment of 5 : 6-mannitoleen tetra-acetate with hypobromous acid, according to the method of Raphael[6], and reaction of the crude bromohydrin with a mixture of acetic acid, acetic anhydride, and fused sodium acetate, yielded D-sorbitol hexa-acetate (V), m.p. and mixed m.p. 97–98°, $[\alpha]_D^{20°}$ + 9·04°. No mannitol hexa-acetate, the other possible product, could be detected. Similarly, from sorbitoleen tetra-acetate, L-iditol hexa-acetate, m.p. 119–120°, $[\alpha]_D^{22°}$ − 26·8°, was obtained, no sorbitol hexa-acetate being encountered.

Full details will be published elsewhere. One of us (P. B.) desires to thank the Department of Scientific and Industrial Research for a maintenance grant.

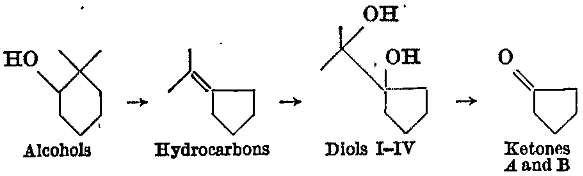
Position of the Hydroxyl Group in Lanosterol

DEHYDRATION of alcohols of the lanosterol series to the corresponding hydrocarbons has recently been reported by us[1], when the action of both phosphorus pentachloride and phosphorus oxychloride was described. Dihydroagnosterol and dihydrolanosterol, when treated with phosphorus pentachloride, gave *iso*-agnostadiene ('iso-γ-lanostatriene'), $C_{30}H_{48}$, and *iso*-lanostadiene, $C_{30}H_{50}$, respectively, and hydrocarbons isomeric with the above dehydration products were obtained with phosphorus oxychloride. We expressed the opinion, based on a consideration of analogous cases in triterpene chemistry, that the phosphorus pentachloride dehydration involved a retropinacoline rearrangement accompanied by a contraction of the terminal ring *A* of lanosterol, and stated that experiments to confirm this view were in progress. In the meantime, Ruzicka *et al.*[2], following our method of preparation, have reported the results of oxidation experiments on the dehydration product from dihydrolanosterol, and afforded evidence in support of the reaction mechanism suggested above, establishing at the same time the position of the secondary hydroxyl group in lanosterol. The continuation of our work has involved the study of the same series of reactions applied both to *iso*-agnostadiene and *iso*-lanostadiene, and in view of Ruzicka's publication, we now present a brief summary of our results.

Iso-agnostadiene, when oxidized with osmium tetroxide, gave a mixture of two diols of formula $C_{30}H_{50}O_2$, which differ only in the steric configuration of their hydroxyl groups and were separated by chromatographic analysis. Both *diol I*, $C_{30}H_{50}O_2$, m.p. 140–142° (found: C, 80·97; H, 11·47 per cent; $C_{30}H_{50}O_2$ requires: C, 81·45; H, 11·31 per cent), and *diol II*, $C_{30}H_{50}O_2$, m.p. 128–130° (found: C, 80·68; H, 11·20 per cent), gave, on oxidation with lead tetra-acetate, the *ketone A*, $C_{27}H_{42}O$, m.p. 85–87° (found: C, 84·51; H, 10·59 per cent; $C_{27}H_{42}O$ requires: C, 84·82; H, 10·99 per cent), while acetone (isolated as the 2-4-dinitrophenylhydrazone) was obtained in almost theoretical yields. The same series of reactions was carried out with *iso*-lanostadiene, yielding diols III and IV, $C_{30}H_{52}O_2$, and the corresponding ketone *B*, $C_{27}H_{44}O$ (Ruzicka's substance V), the constants of which were in essential agreement with the values given by Ruzicka *et al.* (*loc. cit.*). *Iso*-agnostadiene and *iso*-lanostadiene were further subjected to ozonolysis, when acetone and the respective ketones *A* and *B* were obtained in one stage.



The loss of acetone with formation of a ketone, when the diols obtained by osmium tetroxide oxidation of *iso*-agnostadiene and *iso*-lanostadiene are further oxidized with lead tetra-acetate, indicates the presence of a terminal *iso*-propylidene grouping in these hydrocarbons. The retropinacoline rearrangement occurring when triterpenoid alcohols are dehydrated with phosphorus pentachloride[3] thus takes place also in the analogous formation of *iso*-agnostadiene and *iso*-lanostadiene, and establishes the location of the hydroxyl group in the lanosterol molecule in the terminal ring, in a position adjacent to the *gem.*-dimethyl group. A detailed account of this work will appear elsewhere in due course.

Specific Solvents for Lower Rank Bituminous Coals

In the course of recent studies of the effect of solvents on bituminous coals, a number of solvents have been found to share with pyridine and with ethylene diamine[1] the property of extracting a considerable quantity of coal at atmospheric temperatures. The difference between these and other solvents is sufficiently marked to warrant their designation as specific solvents for coal. The main types of specific solvent appear to be: (1) aliphatic compounds containing at least one primary amino group; (2) aromatic compounds containing at least one primary amino group attached to an aliphatic side-chain; (3) certain heterocyclic nitrogen compounds, such as pyridine, piperidine, morpholine (but not piperazine or pyrrole). The specificity of the interaction is emphasized when piperazine and dioxan (inactive) are compared with morpholine and piperidine (active). Slow diffusion of the solvent through the solid often tends to obscure the issue, especially with solvents of high viscosity.

Sufficient solvents have not yet been tested to enable a hypothesis to be formulated. It is already evident that the effect is complex, depending probably upon a suitable combination of at least two properties, one promoting swelling and loosening of the structure, the other solution. At room temperature many compounds (for example, phosphorus oxychloride and ethylene oxide) cause pronounced swelling, but little or no solution; the reverse combination has not been observed. The apparent dependence of solution upon swelling has also been noted by Losikov[2]; a general connexion between the two phenomena, as regards different ranks of coal, was found by several earlier investigators[3].

It is of interest to consider the extraction[1] of lower rank coals with ethylene diamine at its boiling point in the light of Kiebler's generalization[4] that the percentage of bituminous coals extracted by a number of different solvents at a given temperature is correlated with the internal pressure of the solvent better than with any other physical property. There are many conspicuous exceptions to this rule (for example, water), which give too low a yield. Direct comparison is not possible since Kiebler's results are expressed in the form of four correlation lines representing experiments at 150° C., 200° C., 150° C. and 300° C. respectively, whereas ethylene diamine boils at about 117° C. However, if points taken from Kiebler's lines (extended where necessary) at the appropriate internal pressure (117 cal./c.c.) are plotted against temperature, and the resulting curve is extended to 117° C., the expected yield appears to be less than one-third of that obtained experimentally.

Pyridine, which extracts coal at room temperature, and aniline, which is effective only at higher temperatures, both occupy similar relative positions (above the average) in Kiebler's correlation. The differences between these classes probably tend to decrease at higher temperatures. But it seems reasonable to treat the specific solvents (such as ethylene diamine) as a class distinct from those of intermediate solvent power, and from those which are exceptionally inactive, like water.

It is clear that whereas, in such solvents as water and the glycols, hydrogen bonds linking hydroxyl groups contribute largely to the latent heat of vaporization (and therefore to the internal pressure), their presence does not impart the power of functioning as a solvent for coal.

CHEMOTHERAPY OF FILARIASIS

WORKERS engaged in the search of a cure for filarioid infestations in man and animals will welcome the publication* of a symposium of fifteen papers by thirty-eight contributors who attended a conference on "The Chemotherapy of Filariasis" under the auspices of the Section of Biology of the New York Academy of Sciences on October 17 and 18, 1947. The term 'filariasis' in this publication signifies an infestation with a member of the nematode super-family Filarioidea. The use of this term recalls the days when the nematodes recovered from the lymphatic, circulatory or connective tissues or from the serous cavities of man and the lower vertebrates were all grouped in the genus *Filaria*, Mueller, 1787. Purists in medical and veterinary sciences, adopting the present-day classifications of taxonomy in biology, may maintain rightly that the term 'filariasis' should no longer be employed to indicate all infestations due to members of the genera *Onchocerca, Loa, Wuchereria, Acanthocheilonema, Mansonella, Dirofilaria*, etc. The use of the terms 'onchocerciasis', 'loaiasis', etc., indicates specifically the genera involved.

L. T. Coggeshall deals briefly with the history of filariasis due to *W. bancrofti* in the United States, and discusses symptomatology, pathology, immunology, prophylaxis and control. He includes remarks on loaiasis, onchocerciasis and dracontiasis. Filarioid infestations are, as a rule, chronic in character. Clinical manifestations may not become evident for years. There is still controversy as to whether the induration of the tissues in cases of elephantiasis, induced by *W. bancrofti* and occasionally by *O. volvulus*, is not due to secondary bacterial invasion. Coggeshall observes that the pathological changes are not typical of streptococcal infections and that they do not respond to agents which have a specific effect on the streptococcus.

No marked degree of immunity against further re-infection has been detected in individuals already infested, and cases of the same individual being infested with two or more members of the super-family are not uncommon. Coggeshall estimates that up to two million human beings are infested with worms of this group, while other American workers claim that the victims number twenty million. The incidence in domestic animals (horse, ox, sheep, goat, pig, camel, dog, cat, etc.) is high and widespread even in temperate climates. There is no doubt that the efficiency, productivity and welfare of many countries in the tropics and subtropics are seriously impaired by filarioid infestations in man and his livestock.

The low mortality associated with these forms of helminthiasis has rendered the general public indifferent to the sufferings of the afflicted. In the endemic regions, the efforts of the public health authorities to control and eradicate these maladies by prophylactic measures are handicapped by many difficulties, and Coggeshall hopes that the discovery of an effective chemotherapeutic agent would facilitate the elimination of infections from the endemic areas.

The general experimental methods used in studying 'filaricides' are discussed by R. I. Hewitt. The cotton rat (*Sigmodon hispidus*), naturally infected with a filariid, *Litomosoides carinii*, has been found a most suitable experimental animal for testing the efficiency of 'filaricides'. Dogs, infected with the blood filariid, *Dirofilaria immitis*, are used for comparative and confirmative work; but they are considered too large for use in ordinary routine work. The estimation of the efficiency of a 'filaricide' against the species parasitizing the cotton rat is based on destruction of the microfilariæ and its action on the adult worms. Hewitt attributes the disappearance of the microfilariæ in infected cotton rats to the death of the adult worms and not to a direct action upon the microfilariæ. He experimented with various piperazine compounds and admits that the use of controlled quantitative infestations has many advantages over naturally established infections; he considers that the relationship between drug dosage and the intensity of infestation can be gauged best in standardized infections. He notes that the filariids of the cotton rat, dog and man belong to different genera and that the different worms may respond differently to the same drug; but he believes that the utilization of infected cotton rats for testing the filaricidal efficiency of drugs may facilitate the discovery of a 'cure' in man.

G. F. Otto and T. H. Maren discuss the use of arsenicals in filarioid infestations. The literature and their own investigations indicate that the trivalent organic arsenicals are active in both human and canine infestations. Arsenamide kills *D. immitis* in dogs and, in well-tolerated doses, has been found to destroy the microfilariæ of *W. bancrofti*. They add: "It remains to be determined whether or not the adults of *W. bancrofti* are killed by this treatment". H. W. Brown reports on the treatment of filariid infestations with anthiomaline in the dog, cotton rat and man, and records that this compound reduced permanently the microfilariæ counts in individuals infested with *W. bancrofti*. The necessity for repeated injections, and also its toxicity, limit its usefulness, and Brown considers it only 'a stepping-stone' to be replaced by an orally administered non-toxic remedy. James T. Culbertson concludes: "*Wuchereria bancrofti* can be eradicated from many patients by the intensive administration of any of the several compounds of antimony and arsenic". He records that the pentavalent antimonial, 'Neostibosan', is well tolerated by man and has a marked destructive effect on the worms.

Twenty-five volunteers suffering from onchocerciasis were treated by F. C. Barther, T. A. Burch, D. B. Cowie, L. L. Ashburn and F. J. Brady with trivalent antimony compounds ('Stibophen' and tartar emetic). They observed no decrease in the number of microfilariæ or loss of motility in the adult worms. In one case, the administration of tartar emetic, prepared from radioactive antimony, showed that antimony had been taken up by the worm in one nodule. Harry M. Rose deals with the tolerance of antimony and arsenic compounds in intensively treated patients. The drugs used were: 'Neostibosan', 'Neostam', 'Fuadin', 'Anthiomaline' (Specia), 'Anthiomaline' (Merck), urea, stebamine, tartar emetic and stebanose.

Ernest Bueding reports that cyanine dyes in concentrations as low as one in forty millions inhibit the oxidative metabolism of *L. carinii*. The lethal action of cyanines in the case of *L. carinii* infestations is attributed to inhibition of the respiratory metabolism. He observes that, in contrast to vertebrates, the metabolic characteristics of invertebrates may vary greatly from species to species, and that morphologically related parasites need not necessarily be sensitive to the same chemotherapeutic agents. He rightly observes that investigations of the biochemical characteristics of pathogenic parasites may lead to the replacement of the present empirical methods by more rational methods of treatment. Lawrence Peters records that certain cyanine dyes had no chemotherapeutic effect on *W. bancrofti* although they proved lethal to *L. carinii.* He believes that this must be attributed, not to the failure of the drug to reach *W. bancrofti,* but to a difference in the metabolic characters of the two species.

---

* "The Chemotherapy of Filariasis", by various contributors. Vol. 50, art. 2. pp. 19–170 (*Ann. N.Y. Acad. Sci.*, 1948).

S. Kushner, L. M. Brancone, Hewitt, W. L. McEwen, Y. SubbaRow, H. W. Stewart, R. J. Turner and J. J. Denton discuss the preparation of the piperazine compounds used in the search for an active filaricide which can be administered orally and is non-metallic. Hewitt, D. E. White, Kushner, W. S. Wallace, Stewart and SubbaRow report on the 'filaricidal' properties of various piperazine compounds, particularly 'Hetrazan', in dogs and cotton rats. Several of the compounds produced immediate and sharp reductions in microfilaria counts in infected cotton rats when administered orally or intraperitoneally; sometimes relapses occurred. 'Hetrazan' was also lethal to the adult worms in dogs and cotton rats. These workers record that they failed to find dead worms at autopsy in some of the treated dogs, and it seems possible that these dogs were infested not with *D. immitis* but with *D. acutiuscula,* which occur in the subcutis and have been reported from the Canadian lynx (*Lynx canadensis*). They examined only the heart and lungs for dead worms. B. K. Harned, R. W. Cunningham, Sybella Halliday, R. E. Vessey, N. N. Yuda, Mary C. Clark and SubbaRow give the structural formula of 'Hetrazan', report on its toxicity for mice, rats, guinea pigs, rabbits, cats and dogs, and cite some of its pharmacological properties.

D. Santiago-Stevenson, J. Oliver-Gonzalez and Hewitt report on the treatment with 'Hetrazan', taken by the mouth, of twenty-six individuals infected with *W. bancrofti.* The dosage varied from 0·5 mgm. to 2 mgm. per kgm. of body-weight thrice daily for periods varying from three to twenty-two days. For optimum results they suggest a dosage of 2 mgm. per kgm. body-weight thrice daily for a period of two to three weeks. There was a rapid disappearance of microfilariæ from the blood, and the development of nodular swellings at certain points of the body, usually infested by the adult worms, is accepted as proof that the compound killed some of the adult worms.

A study of "The Chemotherapy of Filariasis" will reveal that the search for a cure for filarioid infestations in man and his stock cannot be conducted behind 'iron curtains'. The workers in the various fields of science must co-operate and collaborate more and more closely than is usually the case. A better knowledge of the chemical composition and the metabolism of the various helminths parasitizing man, animals and plants may contribute materially towards the discovery of 'cures' which will not only relieve, to some degree, the present world-wide shortages of food, but will also restore normal health to many all over the world. P. L. LEROUX

SOIL THERMODYNAMICS AND ROAD ENGINEERING

By J. D. COLEMAN

Road Research Laboratory, Harmondsworth, Middlesex

THE movement of moisture in soil is of importance to the civil engineer owing to the effect which changes in moisture content may have on the strength and the volume of the soil. In the case of roads, both the stability and the riding qualities of the surface are involved.

The thermodynamics of the moisture contained in hygroscopic materials such as paper, tobacco and textiles has received considerable attention, and much has already been done, particularly by agricultural scientists, in applying this work to soils. A fundamental approach on these lines to the many problems associated with the transfer of moisture in road foundations is at present being made at the Road Research Laboratory.

The potential causing the migration of soil water may be regarded either as a hydraulic pressure or a vapour pressure gradient. Movements cease only when suction and vapour pressure conditions are in equilibrium with the acting gravitational field under the prevailing temperature conditions.

The curvature of each of the air/water interfaces in the soil pores is a function of the pressure change through the meniscus and of the relative humidity at the interface. The relationship between relative humidity is given to a close degree of approximation by the well-known Kelvin equation, which may be written,

$$\frac{\rho.R.\theta}{M} \cdot \log_e \frac{H}{100} = - \frac{2T}{r}. \qquad (1)$$

The actual change in pressure through the meniscus, $\rho.g.h = 2T/r$, can be expressed in terms of Schofield's *pF* function[1],

$$pF = \log_{10} h = \log_{10} \frac{2T}{\rho.r.g}. \qquad (2)$$

Equations (1) and (2) have been used by Schofield and others in the determination of the *pF* of soils at low moisture contents.

In the soil itself, the curvature of the air/water interfaces depends on the moisture content and on certain characteristics of the soil solids, the chief of which appears to be the particle-size distribution. It follows that the suction/moisture content and the relative humidity/moisture content relationships depend on soil type; and, in fact, the moisture contents of two dissimilar soils in moisture equilibrium may be greatly different. In road construction, where it is common on clay soils to use a stable sandy soil to form part of the road foundation, the suction/moisture content relationships are useful in estimating the equilibrium moisture (and strength) conditions.

Road foundations are subjected to both the daily and the yearly temperature cycles. It is therefore necessary to ascertain the effect of temperature on the suction and humidity relationships. The variation of the density of the soil water with temperature causes only a second-order variation in the radii of the air/water interfaces. Neglecting this variation, it follows from (2) that at two temperatures θ_1 and θ_2,

$$pF_{\theta_1} - pF_{\theta_2} = \log_{10} T_{\theta_1} - \log_{10} T_{\theta_2} + \log_{10} \rho_{\theta} - \log_{10} \rho_{\theta_1}. \qquad (3)$$

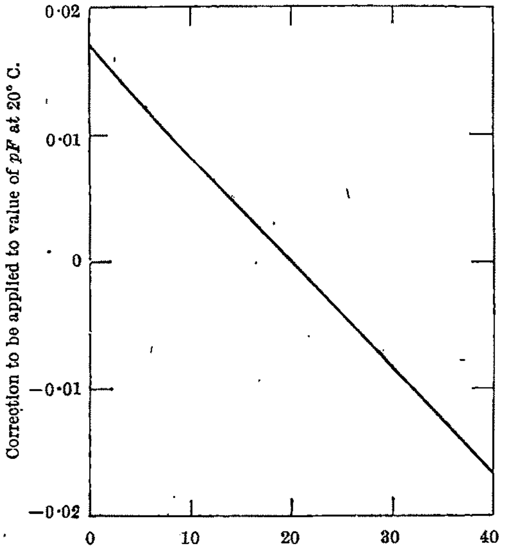

Fig. 1. Correction to be applied to pF of soil at 20° C. to obtain pF at other temperatures

Fig. 1, obtained from this equation, shows how small the suction difference associated with temperature gradients will be. The correspondingly small variation with temperature of the relative humidity of soil water follows from equation (1), since

$$\frac{\log_e H_{\theta_1}/100}{\log_e H_{\theta_2}/100} = \frac{T_{\theta_1}}{T_{\theta_2}} \cdot \frac{\theta_2}{\theta_1} \cdot \frac{\rho_{\theta_2}}{\rho_{\theta_1}}. \qquad (4)$$

This relationship is used to obtain Fig. 2.

The small change in relative humidity with temperature indicates that the vapour pressure of soil water varies with temperature in a manner similar to that of free water. A family of typical vapour pressure/temperature/moisture content curves is shown in Fig. 3. It follows that considerable vapour pressure gradients may be set up by comparatively small temperature differences. Further, since the relative humidity of soil water is sensibly different from 100 per cent only at moisture contents lower than those of interest to the road engineer, the following two conclusions can be reached:

(1) Differences in soil moisture content under the road will cause suction gradients virtually unaccompanied by vapour pressure gradients, and transfer will normally be in the liquid phase.

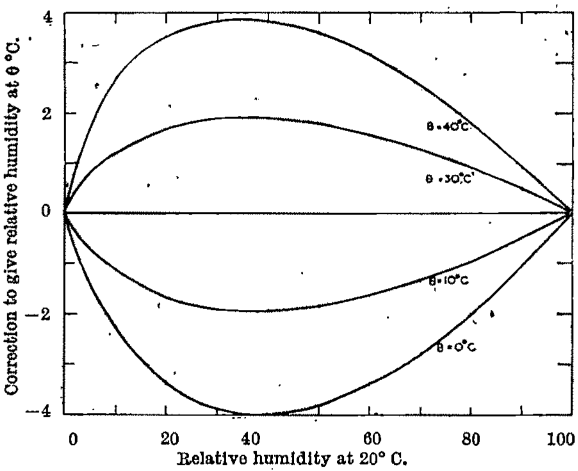

Fig. 2. Correction to be applied to relative humidity of soil at 20° C. to obtain relative humidity at other temperatures

(2) Differences in temperature will cause vapour pressure gradients but not appreciable suction gradients, and transfer will normally be in the vapour phase.

Interesting confirmation of these conclusions has been obtained in this Laboratory and from practical observations. The severe drought in 1947 caused an abnormal reduction in the moisture content of road verges. Transfer of moisture in the liquid phase resulted in severe settlement and cracking on a number of roads built on heavy clays. In some parts of the world, seasonal temperature gradients are such as to cause the upward migration of water from considerable depths. Reports have been received from arid regions of California of vegetation confined solely to the verges of roads where evaporation of moisture brought to the surface was prevented by the impermeable road metal.

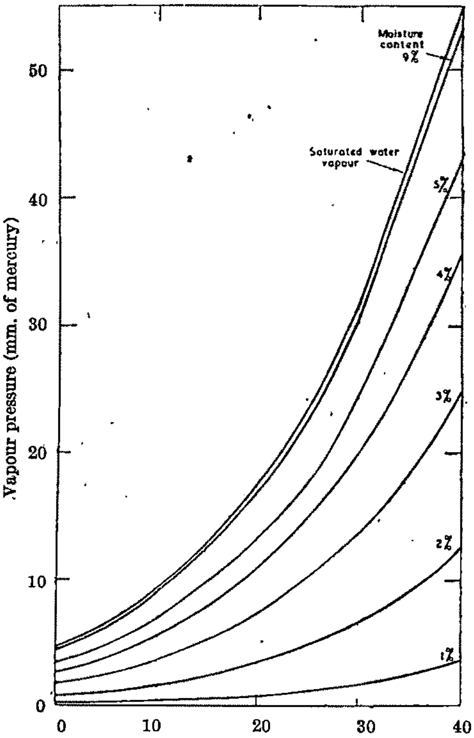

Fig. 3. Variation of soil vapour pressure with temperature

The problem of moisture transfer also involves consideration of the heat of wetting, the latent and specific heats of the soil water and the effect of temperature on each of these quantities. Detailed consideration has been given so far only to the heat of wetting. The differential heat of wetting of a hygroscopic material is obtained by Shorter[2] as

$$Q = -\frac{R\theta^2}{JM} \cdot \frac{\partial}{\partial\theta}\left[\log_e \frac{H}{100}\right]. \qquad (5)$$

Using the differential of equation (1)

$$Q = \frac{-R\theta^2}{JM} \cdot \left[\frac{1}{T} \cdot \frac{\partial T}{\partial\theta} - \frac{1}{\theta} - \frac{1}{\rho} \cdot \frac{\partial\rho}{\partial\theta}\right] \log_e \frac{H}{100}. \qquad (6)$$

Equation (6) enables the differential heat of wetting to be calculated at any given temperature. At temperatures θ_1 and θ_2, equations (6) and (4) give

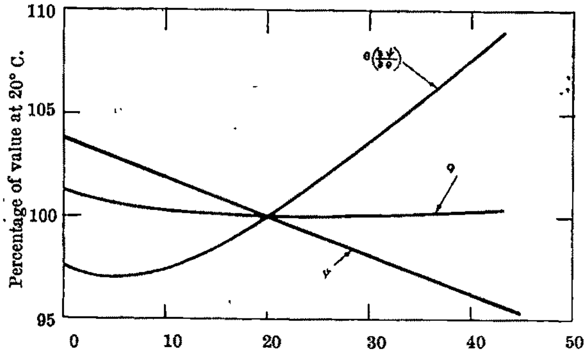

Fig. 4. Temperature variation of capillary potential, ψ, heat of wetting and bound energy, $\theta\,(\partial\psi/\partial\theta)$

$$Q_{\theta_1} = Q_{\theta_2}\frac{\left[\frac{1}{T_{\theta_1}}\left(\frac{\partial T}{\partial\theta}\right)_{\theta_1} - \frac{1}{\theta_1} - \frac{1}{\rho_{\theta_1}}\left(\frac{\partial\rho}{\partial\theta}\right)_{\theta_1}\right]\theta_1 \,.\, T_{\theta_1}\rho_{\theta_2}}{\left[\frac{1}{T_{\theta_2}}\left(\frac{\partial T}{\partial\theta}\right)_{\theta_2} - \frac{1}{\theta_2} - \frac{1}{\rho_{\theta_2}}\left(\frac{\partial\rho}{\partial\theta}\right)_{\theta_2}\right]\theta_2 \,.\, T_{\theta_2}\rho_{\theta_1}}. \tag{7}$$

Equation (5) can be written in the form

$$Q = \psi - \theta\, d\psi/d\theta,$$

where ψ, Buckingham's capillary potential, $-gh$, is given by

$$\psi = \frac{R.\theta}{M} \,.\, \log_e \frac{H}{100}.$$

In Fig. 4 the temperature variation of Q and each of its components ψ and $\theta\,.\,\partial\psi/\partial\theta$ is given. These curves are based on equation (7). The quantity $\partial T/\partial\theta$ was obtained from accurate surface tension data.

Further investigations are in hand, and it is hoped to publish a fuller account, including experimental results, in due course. The work is being undertaken as part of the programme of the Road Research Board, and the present note is published with the consent of the Director of Road Research.

DEVELOPMENTS IN PICTURE TELEGRAPHY

THE transmission of pictures by land-line over various distances has been the subject of experimental development since the earliest days of telegraphic communication; and the techniques involved have been adapted similarly for transmission or relaying over radio links. Amid the excitement of other applications in recent years, such as broadcasting, radar and television, the very advanced stage which has been attained by picture or facsimile telegraphy, as the technique is termed, is apt to be overlooked. Many systems have been suggested and experimented with; but they have had a common basis in that the picture to be transmitted is placed on a revolving drum and scanned with a suitable source of light and optical system. The variations in light intensity reflected or scattered by the varying tones of the picture are converted into a fluctuating electric current through the agency of a photoelectric cell. The resulting signals are transmitted by line or radio to the receiving station, where they may be converted by a current-sensitive oscillograph into light variations which record the picture on suitable photographic paper. Alternatively, the electric currents are made to reproduce the picture by an electrochemical process. In either case, the recording paper is mounted on a drum which is maintained in rotation synchronously with that at the transmitting station.

This technique of the transmission of pictures by telegraphy is used to a large and successful extent by the Press to obtain quickly the illustrations which accompany accounts of topical events all over the world. But there are other applications in industry and the public service; and one of these, the transmission of fingerprints by radio, has been referred to in *Nature*, **158**, 525 (1946).

The name of Muirhead has been associated for more than a century with the development of instruments used in various branches of telecommunications, including in recent years the very successful production of phototelegraphic equipment. At the recent symposium held by the Scientific Instrument Manufacturers Association of Great Britain, Ltd., a paper entitled "Some Developments in Picture Telegraphy" was presented by Mr. J. Bell, of Muirhead and Co., Ltd., who have also supplied some technical literature and bulletins giving further details of the equipment. For some time now a number of the larger newspapers have operated their own picture transmission circuits comprising telephone lines linking their editorial offices with various population centres; and Muirhead–Jarvis picture-telegraph transmitting and receiving equipment is now in operation in a large number of newspaper offices in Great Britain and northern Europe. The apparatus has been designed to conform with the requirements laid down by the Comité Consultatif International Télégraphique (C.C.I.T.), and it may therefore be worked with the principal phototelegraphic services abroad which conform to the same standards.

An amplitude-modulated form of transmission is used over wire circuits, while for radio links the principle of sub-carrier frequency-modulation is used, thereby ensuring that the signals representing the tone values of the picture are not greatly affected by fading and other disturbances of the radiofrequency carrier-wave during transmission. The picture transmission band is from 300 to 2,300 cycles per second and is thus easily within the scope of a normal telephone channel.

The standard equipment installed at the terminal fixed stations uses drum speeds of either 1 or 2 revolutions per second, and the picture is scanned at either 100 or 150 lines per inch (3·9 or 5·9 lines per mm.) for all normal requirements. Under these conditions, a picture of size 10½ in. by 10 in. (267 mm. by 254 mm.) can be transmitted in 16 min. 40 sec. and 25 min. respectively. For super-quality work, scanning at 300 lines per inch (11·8 lines per mm.) can be used, and the results obtained under these conditions are so accurate in detail as to render it difficult to distinguish the received picture from the original.

The use of normal telephone channels for the communication of news direct from the scene of the event has been followed by a demand for comparable facilities for the transmission of pictures, and the Muirhead–Belin portable transmitter has been developed to meet this demand. This equipment consists of two suit-case units, one of which contains the power unit operating either from the electricity supply mains or from a car-starter battery. The other unit comprises the transmitter, which conforms with the C.C.I.T. requirements as regards picture size, rate of scanning, synchronizing, phasing and speed of transmission; it can therefore be used in conjunction with any make of receiver similarly standardized. As with the fixed station equipment, the speed of the revolving drum carrying the picture is maintained constant by means of a special synchronizing circuit controlled by a temperature-compensated high-stability tuning fork. The frequency of this fork is 1,020 c./s., and this is used to modulate a sub-carrier signal of 1,300 c./s., which is transmitted down the line, to provide at the receiver a synchronizing signal which is independent of any changes occurring in the telephone carrier-signal.

There is also available a portable dark-room, comprising a small tent and full photographic facilities, and this is fitted up in two suit-cases for use with the portable picture transmitter. This equipment allows the processing of pictures to be carried out quickly and conveniently in any location.

The bulletins referred to above contain several photographic reproductions in support of the claim that "Muirhead machines are producing the best wired pictures in the world".

ANCIENT ARTS AND MODERN PARODIES

THE exhibition entitled "40,000 Years of Modern Art", which opened at the Academy Hall in Oxford Street, London, just before Christmas and closes at 10 p.m. on January 29, makes no claim to a scientific approach—to which, indeed, so cavalier a title would have been rather ill attuned—yet it possesses surpassing interest for anthropologists, and may well do a good service to science by inducing them, and other visitors, to look at primitive art in new ways under the shock of the juxtaposition with a sufficiently aggressive selection of modern paintings and sculptures. The Institute of Contemporary Arts, 6 Fitzroy Street, London, W.1, a recently formed body devoted to the good cause of encouraging new trends in all the arts (but the approach of which is perhaps not yet quite so wide as its scope), is to be warmly congratulated and thanked for assembling what is almost certainly the most impressive display of primitive art ever held in Great Britain outside the great ethnographical museums.

The selection, though partly conditioned by the desire to find parallels for the moderns, has not suffered unduly thereby, and there are only a few pieces (such as a dubious Easter Island figure) which seem to have been included less for their merit than their surrealism. Many, if not most, of the Oceanic and (especially) African pieces are of the very first class within their types; some cannot be paralleled here at all. The Pitt Rivers and Ashmolean Museums at Oxford, the Horniman Museum and the Brighton Museum have all made notable contributions, and the magnificent private collections of Mr. Webster Plass and Mr. W. O. Oldman have been drawn upon to excellent effect. Among the finest pieces are the most forceful of all Basonge masks (Belgian Congo), owned by Mr. R. Penrose; Mr. Plass' bust of a Baga fertility divinity (French Guinea); the Northern Yoruba earth goddess from the Horniman Museum; two large fetish figures of the eastern and western Belgian Congo from the Oldman collection; some fine reproductions from the Frobenius Institute at Frankfurt of Australian and African rock paintings; and an outstanding series of polychrome *malanggan* carvings from the New Ireland collection at Brighton. The word 'primitive' has been rather strictly interpreted, to exclude the barbaric 'civilizations' of West Africa, Indonesia and pre-Columbian America, and this has meant that certain forms of sculpture pre-eminently appropriate to this exhibition (such as the more mystical of the Benin bronzes) are unrepresented. Less easy to explain is the truly primitive sculpture of Borneo and other parts of the East Indies.

The declared purpose of the exhibition is to compare primitive and modern and to suggest a community of inspiration between them. But one's main impression on leaving the show (and this is confirmed by most of the art critics) is rather of antithesis. It is true that there are superficial resemblances of form (though many of those to which the organisers direct attention are, in fact, purely fortuitous); but fundamentally they are opposed in conception and function. Primitive art is everywhere (even in medieval Europe) an art of conformity, of devoted acceptance in both a spiritual and a material sense; the forms develop over hundreds, or even thousands, of years, by processes which are essentially evolutionary, and have a four-dimensional quality about them which arises from their conception not by a single artist, but by many generations of artists, not as an escape, but as at once the expression and the support of the social pattern. 'Modern' art, on the contrary, is to a large extent frankly revolutionary, and, moreover, is still, after forty years, in the destructive phase of anarchism, comparatively few artists having begun, like Henry Moore (who almost alone in this exhibition seems to hold his own with the peoples of Nature), to build the foundations of a new order amid the chaos; too many of them are iconoclasts, content to satirize our world by drawing, for their entirely intellectual inspiration, upon the form but not the content of the deeply religious art of the primitive peoples (with the same cynicism with which an atheistic totalitarianism will tolerate or even sponsor a subservient form of Christianity for its own ends). In this deeper sense, then, primitive art is actually nearer in spirit to the traditionalism of the Royal Academy than to the exuberance of its own imitators. Sincerity, it may be thought, is the most flattering form of imitation.

We may be all the more grateful to the Institute of Contemporary Arts for putting the moral so clearly before us that there is a virtual unanimity among both critics and members of the public. The Institute has thus laid a fine foundation for its future work, and we may look to it with confidence and hope for the constructive leadership which will not only give direction and stability to modern art in the post-Picasso era, but also make its contribution to a re-integration of the cultural elements in our schizophrenic society.

Two further words should be said: the arrangement of the exhibition, though bold and imaginative, strains perhaps a little too self-consciously after the sales technique of a show of industrial design, instead of the self-effacement proper to the display of works of art; and the catalogue (though not wholly innocent of the same tendency) contains an essay by W. G. Archer and Robert Melville which is a valuable stimulant to thought about primitive and modern art and their interrelations, and in which both artists and ethnologists may find not a few provocative sentences. We may hope that the collaboration between art and science will be pushed much further.

WILLIAM FAGG

SECULAR CHANGES IN THE EARTH'S MAGNETIC FIELD

DR. E. C. BULLARD has described (*Mon. Not. Roy. Astro. Soc.*, Geophys. Supp., 5, No. 7, July 1948) the rapid changes in the earth's magnetic field in South Africa, from which certain tentative conclusions are drawn. From data in tables 25, 29 and 33 in "Descriptions of the Earth's Main Magnetic Field and its Secular Changes", by E. H. Vestine and others (Carnegie Institution, Washington, 1947), a diagram is constructed showing the annual changes in the horizontal and vertical fields in South Africa at 1922·5; this date has been chosen because it is believed that the secular variations are better known then than at any other time.

From detailed calculations it seems possible that motions in the liquid core of the earth can partly explain the rapidity of change, though, as shown in the calculations, it is difficult to obtain a sufficient field by these means. Some of this difficulty, it is hoped, may be removed by a more thorough analysis of the secular change. The movement of the material of the earth's core through the general magnetic field of the earth could induce electric currents which produce the secular changes in the magnetic field, and the world-wide part of the change may be due to motions some thousands of kilometres in diameter. From 1843 to 1900 the change at Cape Town was comparatively small (0·02 gauss in all) and may not have been due to a local eddy.

No explanation is given regarding the causes of the motions in the liquid core, but it is suggested that radioactive generation of heat there might produce thermal convective currents. A similar effect would result from asymmetry in the earth's cooling, and another possibility is that the slipping of the outer part of the earth over the core, while the earth's rotation slows down by tidal friction, may have had some effect.

A full investigation of the theory proposed would be a tedious matter, and it is not suggested that it is complete at present, but it is hoped that it will "stimulate modifications that will agree more exactly with the very complicated facts".

RUBBER INDUSTRY IN GERMANY

THE B.I.O.S. Overall Report No. 7 on "The Rubber Industry in Germany during the Period 1939–1945" has recently been published (London: H.M. Stationery Office, 1948. 2*s*. 6*d*. net). This comprehensive report will be primarily the concern of the rubber technologist, but there are a number of aspects which will interest all scientific workers in the high-polymer field. Perhaps the most interesting is the heat sensitization of latex by the use of polyvinyl ether ('Igevin M50'), because the process depends upon the curious fact that this material is soluble in latex or water at room temperatures, but becomes insoluble at 35° C., and causes the rubber to coagulate as it separates out. 'Igevin M50' is used in 3–7 per cent concentration referred to the rubber content, and the mixed solution is indefinitely stable at 25° C., thus contrasting markedly with other heat-sensitizing materials.

The German synthetic rubber industry started long before the American industry, and it has been of interest to note that, in each case, the bulk of the synthetic rubber produced was of the butadiene–styrene type, with butadiene–acrylonitrile polymers running second. What has not been generally realized, however, is that the Germans also had a large number of varieties, not only of the butadiene–styrene type, but also of other types, and these are described on pages 22–30 of the report. Two promising polymers of which little has previously been heard are 'Buna K', a copolymer of butadiene and methyl vinyl ketone, and 'Buna M', where butadiene was polymerized with methyl methacrylate.

Another synthetic rubber which seems to show remarkable promise is 'Vulkollan N'. This is an ester-type rubber, prepared from polyethylene adipate and naphthalene di-*iso*cyanate, which it is claimed will render all other polyester rubbers obsolete, being non-hardening, of high tear-resistance, and having lower hysteresis. Its resistance to abrasion is said to be ten times that of natural rubber, the tear-resistance is 53 per cent higher, and the solvent resistance is equal to that of 'Perbunan'; it will be interesting to see whether the manufacture of this rubber can be made a commercial proposition.

In the field of testing, the Germans were actively aware of the prime importance of laboratory tests for the 'processability' of their polymers, and they developed many tests which will be of interest to those technologists who had to struggle with the intractable rubbers which were the early product of the American industry. Other subjects of particular interest to technologists are the new non-black reinforcing fillers 'Tonerdegel' and 'White Carbon', the account of abrasion machines, and the discussion of thermal plasticization.

R. G. NEWTON

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, January 24

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 4.45 p.m.—Dr. P. Johnson: "The Ultracentrifuge and Electrophoresis Apparatus in Protein Research".* (Further Lectures on January 31, February 7 and February 14.)

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5 p.m.—Prof. C. G. Rossby: "Air Mass Meteorology—its Geographical Implications".

INSTITUTION OF ELECTRICAL ENGINEERS (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Generation of Electricity by Gas Turbine Plant".

MANCHESTER LITERARY AND PHILOSOPHICAL SOCIETY (in the Reynolds Hall, College of Technology, Manchester), at 5.30 p.m.—Symposium on "Juvenile Delinquency".*

TEXTILE INSTITUTE, YORKSHIRE SECTION (at Alexandra Café, King Edward Street, Halifax), at 7.30 p.m.—Mr. F. L. Goodall: "The Battle against Textile Pests".

CHEMICAL SOCIETY, OXFORD SECTION (in the Physical Chemistry Laboratory, Oxford), at 8.15 p.m.—Prof. N. V. Sidgwick, F.R.S.: "Some Remarks on the Periodic Table" (Alembic Club Lecture).

Tuesday, January 25

INSTITUTE OF FUEL (at the Institution of Mechanical Engineers, Storey's Gate, St. James's Park, London, S.W.1), at 10 a.m. and 2 p.m.—Conference on "Combined Heat and Power Supplies".*

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Dr. Ian Hogbin: "Social Status in Melanesia".

Eugenics Society (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. L. S. Penrose: "The Work of the Galton Laboratory".*

Institution of Electrical Engineers, South Midland Centre (at the Town Hall, Birmingham), at 6 p.m.—Sir Noel Ashbridge and Mr. H. Bishop: "Television" (Faraday Lecture). (To be repeated on Wednesday, February 2, at the Philharmonic Hall, Hope Street, Liverpool, at 6.45 p.m.; on Wednesday, February 9, at the Houldsworth Hall, 90 Deansgate, Manchester, at 7.30 p.m.; on Wednesday, February 16, at Central Hall, Westminster, London, S.W.1, at 6.30 p.m.; on Wednesday, March 16, at the De Montfort Hall, Leicester, at 7.15 p.m.; on Wednesday, March 23, at the City Hall, Sheffield, at 7 p.m.; on Tuesday, March 29, at the City Hall, Newcastle-upon-Tyne, at 7 p.m.; and on Tuesday, April 5, at the Central Hall, Tollcross, Edinburgh, at 7 p.m.)

Royal Institute of Chemistry, London and S.E. Counties Section (at High Duty Alloys, Ltd., Buckingham Avenue, Trading Estate, Slough), at 6 p.m.—Prof. H. V. A. Briscoe: "The Chemistry of Dusts".

Society of Public Analysts and other Analytical Chemists, Physical Methods Group (in the Chemistry Lecture Theatre, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 6 p.m.—Discussion on "Rheological Methods of Control".

Manchester Geographical Society (in the Geographical Hall, St. Mary's Parsonage, Manchester), at 6.30 p.m.—Mr. J. Arnold Berry: "Three Indian Cities—Bombay, Agra and Delhi".

Wednesday, January 26

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Dr. Thomas Swarbrick: "The Application of Science to Fruit Growing".

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Annual General Meeting: Dr. G. M. B. Dobson, F.R.S.: "Ice in the Atmosphere".

Institution of Electrical Engineers, Radio Section (joint meeting with the Acoustics Group of the Physical Society, at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. E. M. Payne: "The Development of Magnetic-Tape Recorders".

Linnean Society of London (in conjunction with the Systematics Association, at Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. A. J. Wilmott: "Botanical Taxonomy from Linnæus to Darwin".

Manchester Literary and Philosophical Society, Chemical Section (at the Portico Library, 57 Mosley Street, Manchester), at 5.30 p.m.—Mr. H. Stevenson: "Long Term Policy in Chemical Industry, especially in Textiles".

Institute of Welding (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Sir William J. Larke Medal Paper.

British Association of Chemists (in the Small Conway Hall, Red Lion Square, London, W.C.1), at 7 p.m.—Mr. F. A. Robinson: "Antibiotics".

Television Society (at the C.E.A., 164 Shaftesbury Avenue, London, W.C.2), at 7 p.m.—Mr. M. Morgan: "Television Transmission and Reception at 480 Mc./s.".

Society for Visiting Scientists (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion on "Research Teams" (to be opened by Sir George Thomson, F.R.S., Sir Charles Harington, F.R.S., and Dr. H. O. Wansbrough-Jones).

Thursday, January 27

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. J. B. S. Haldane, F.R.S.: "Some Modern Views on Evolution".*

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Harold Spencer Jones, F.R.S.: "The Royal Greenwich Observatory".

Mineralogical Society (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Royal Institution (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Dr. H. W. Thompson, F.R.S.: "Infra-Red Measurements in Physics, Chemistry and Biology". (Further Lectures on February 3, February 10 and February 17.)

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Dr. F. E. Jones: "Radar as an Aid to the Study of the Atmosphere".

Friday, January 28

Institution of Chemical Engineers, North-Western Branch (at the College of Technology, Manchester), at 2.30 p.m.—Annual General Meeting: Dr. F. A. Freeth, F.R.S.: "The Place of Heterogeneous Equilibrium in Chemical Engineering".

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Geophysical Discussion.

Chemical Society, Southampton Section (joint meeting with the Chemical Society of University College, Southampton, in the Physics Department, University College, Southampton), at 5 p.m.—Dr. R. P. Linstead, F.R.S.: "Some Aspects of Recent Work at the Chemical Research Laboratory, Teddington".

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.15 p.m.—Dr. F. Bergel: "Some Aspects of Pharmacological Chemistry".* (Further Lectures on February 4 and February 11.)

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Discussion on "Fluid Mixing by Jets and Cyclone Dust Collectors".

North-East Coast Institution of Engineers and Shipbuilders (at the Mining Institute, Newcastle-upon-Tyne), at 6.15 p.m.—Mr. H. G. Yates: "Vibration Diagnosis in Marine Geared Turbines".

Manchester Statistical Society, Industrial Group (at the Society of Architects, 16 St. Mary's Parsonage, Manchester), at 6.45 p.m.—Dr. G. P. Sillitto: "The Design of some simple Physico-Chemical Experiments".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Mathematics, to teach up to B.Sc. General Degree standard—The Clerk to the Governors, South-East Essex Technical College and School of Art, Longbridge Road, Dagenham (January 29).

Senior Biochemist or Biochemist—The House Governor, Royal Free Hospital, Gray's Inn Road, London, W.C.1 (January 31).

Readership in Old Javanese at the School of Oriental and African Studies—The Academic Registrar, University of London, Senate House, London, W.C.1 (February 1).

Physicists and Electrical Engineers (unestablished, Senior Scientific Officer and Scientific Officer grades) at the Royal Aircraft Establishment, Farnborough, and other Ministry of Supply establishments in southern England—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.436/48A (February 5).

Lecturer in Metallurgy in the Department of Applied Chemistry—The Secretary, Northampton Polytechnic, St. John Street, London, E.C.1 (February 12).

Assistant Lecturer in Chemistry—The Registrar, The University, Sheffield (February 19).

Lecturer in Engineering with special interest in strength of materials and structures—The Secretary, The University, Aberdeen (February 21).

Senior Lecturer or Lecturer in Physiology in the University College of the West Indies—The Secretary, Senate Committee on Higher Education in the Colonies, University of London, Senate House, London, W.C.1 (March 1).

Chair of Anthropology at Auckland University College (University of New Zealand)—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (March 1).

Readership in Indian Philosophy at the School of Oriental and African Studies—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 28).

Director of the Rubber Research Scheme of Ceylon—The Chairman, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, South Kensington, London, S.W.7 (March 31).

Director of the Institute of Social and Economic Research, University College, Ibadan, Nigeria—The Under-Secretary of State, Research Department, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1 (March 31).

Technical Assistant in Electronics—Dr. B. Bowden, Caius College, Cambridge.

Lecturer in Mechanical Engineering—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11.

Social Anthropologist, for a study of the Ndebele of Southern Rhodesia—The Director, Rhodes-Livingstone Institute, P.O. Box 195, Livingstone, Northern Rhodesia.

Research Assistant for Biochemical Laboratories—The Secretary, Institute of Psychiatry (University of London), Maudsley Hospital, Denmark Hill, London, S.E.5.

Senior Entomologist, and Field Entomologists (3), in the East Africa Desert Locust Survey—The Under-Secretary of State, Colonial Office, Research Department, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Physical Chemists (Scientific Officer grade) at a Ministry of Supply Research and Development Establishment near London, for work in (*a*) high temperature refractories, (*b*) crystallography and practical microscopy, (*c*) spectrography, and (*d*) plant development—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.1025/48A.

Mechanical Engineer to take charge of a department of research on flax production—The Director, Linen Industry Research Association, Lambeg, Belfast.

Agricultural Chemist in the Department of Agriculture, Sierra Leone—The Director of Recruitment, Colonial Service, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

PROBLEMS OF UNIVERSITY EXPANSION IN BRITAIN

DESPITE the general interest of the report of the University Grants Committee as a record of university development in Great Britain during 1935–47 (see p. 154 of this issue), and the picture it gives of the very considerable achievements of British universities both before and during the War, that part of the report which deals with post-war developments and problems is likely to receive most attention. None the less, the greatly increased scope of the activities of the University Grants Committee, to which the whole report bears witness, make it desirable that the early chapters should be read by a much wider public than those who may be immediately affected by the developments or special problems discussed later in the report. The scale on which the universities of Great Britain are now being assisted from national funds makes it imperative that the ordinary citizen should have a clear idea of how those funds are being spent and what the nation is receiving in return. Within its limits the report makes a valuable contribution to that end ; but it may well be held that an increasingly important function of the University Grants Committee in the future will be the interpretation, to the nation as well as to the Government, of the policies and the financial needs of the universities.

The two most impressive features of the present report are its revelation of the extent to which the expansion of the universities urged from many quarters during the War has already taken place, and the confidence of the Committee that the increasing dependence of the universities on State assistance and the central planning of university development so as best to promote the public welfare, at least on the lines indicated in the report, need not endanger academic autonomy. Already the number of students has risen from the pre-war 50,000 to some 77,000 as against the 88,000 which, ignoring financial considerations, the universities had estimated they would be able to deal with at the end of ten years. This latter estimate is only 2,000 short of the total recommended by the Barlow Committee ; and analysis of the figures by faculties indicates that in science and technology the pre-war numbers have already been doubled. Numbers in the faculties of arts, however, have risen by only about 50 per cent, although accommodation for arts students is not in general so limited as for science and technology, and in the arts faculties a higher proportion of applicants gains admission. The University Grants Committee, however, advances sound reasons for its doubts whether the arts faculties are likely in the remainder of the decade to expand by the 10,000 students required to achieve the proposed doubling of numbers in all faculties other than medicine.

The University Grants Committee is not unduly disturbed by the probability that for some years to come the proportion of students engaged in scientific and technological studies is likely to be higher than it was before the War. It points out that the proportions of students in these faculties have varied greatly in different universities, and that what is vital is that in each university the several disciplines should be represented in such proportions that members of the various faculties are brought into contact with students in other fields. Such contact becomes more difficult if the proportion of any one faculty is excessively low or high, and the University Grants Committee suggests that the proportion of arts students should not fall below one-third. It may well be, as suggested, a matter for examination whether the different ratios which have been temporarily established in the total student population in Great Britain during the post-war years represent what is desirable from the national point of view, and also whether it should remain constant. Much more important is the maintenance of quality, of conditions which make possible the effective mingling of the faculties and a proper relation between the number of students in the different faculties and their prospects of employment. These are the factors with which the University Grants Committee is concerned, and it is rightly insisted that the rate at which university expansion can wisely proceed must take full account of all three.

The question of quality naturally involves that of selection, and the Committee's observations on this point are appropriately considered in discussing the recommendations of the 'working party' on university awards (see *Nature*, January 22, p. 113). Next to the quality of the students, however, the maintenance of university standards depends on the quality of the life and education which the universities are able to offer. The University Grants Committee is very seriously concerned with the heavy strains which the rapid expansion has imposed on staff and students alike, and the consequent serious deterioration in the standards of university life. It rightly observes that conditions which may be tolerable for a short period become in time unendurable, and, while less cautious or pessimistic than the Nuffield College Committee in its recent statement, is convinced that unless additional accommodation can be speedily provided, the present numbers of students cannot be maintained without grave risk of impairing academic standards.

On these grounds, it is apparent that if the provision of the additional accommodation so urgently needed in the form of new teaching blocks, halls of residence, libraries and central amenities is not forthcoming when the present considerable proportion of ex-Service men declines, the Committee believes that the universities will be well advised to delay filling their places with younger undergraduates. Maintenance of the present overcrowded conditions with a less mature body of students involves the danger that the really outstanding people will be unable to reach the standards which were attained before the War. The view that provision of a leisured university life, with adequate opportunities for regular contacts between staff and students, should come before any expansion in numbers which denies such opportunities is supported by observations both from the point of view of graduate employment and of the expansion and conditions of the university staffs.

Although university education should not be regarded merely as a means of training for particular careers, some attention, as we have repeatedly urged, must be paid to the rate of expansion in the output from different faculties. While it is important that, besides equipping scientific workers, technologists and medical men for their work, the universities should provide men and women of trained intelligence and wide culture for the solution of social problems, the administration of public affairs and the enrichment of every sphere of human activity, a sense of frustration and disillusionment would be created if many graduates were unemployed, or employed in occupations which made no real or satisfying use of their abilities. It is clearly easier to estimate the future demand for graduates in science and technology; but even here, though much valuable work has been done, the survey is at present far from complete. On the imperfect data available, no more general inference is warranted than that although some adjustment of numbers as between different branches of science and technology may be required, no considerable increase in the present total of such students will be demanded in the foreseeable future.

On the other hand, the future demand for arts graduates is extremely problematic. Despite the reasonable contention that larger numbers of graduates in arts could be employed with advantage to the nation in local government administration, in industry and in commerce, the prospects of any rapid increase in any such openings are hazy. A changed mental attitude is required on the part of graduates, no less than on the part of local authorities and other employers. It is not easy even to estimate the number of recruits for the administrative class of the Civil Service who would be recruited from arts as distinct from science graduates. The University Grants Committee believes that the university appointments boards could make an important contribution; but in the meantime, firmly as it believes that it is essential for our national well-being that means should be devised to permit the recruitment into non-technical employment in industry of a steadily increasing proportion of university men and women, the Committee is right to utter the warning that the present numbers of arts students cannot be maintained or increased without the danger of creating unemployment, unless the avenues for employment are greatly widened.

That in itself may enforce early reconsideration of the balance of studies, as the Committee itself admits. Moreover, if the ratio between the faculties is to be changed without detriment to university standards, regard should be had to the content of the curriculum, especially perhaps so as to correct any tendency to narrowness of outlook on the side of science and technology, as well as to the means of ensuring contact between the students of different faculties, on which the University Grants Committee rightly lays considerable stress. It goes far, indeed, towards commending the suggestion which Sir George Arthur made in the foundation oration at Birkbeck College on March 28, 1946, that in every department one lecture should be given, or one paper read, every week or every month, by a student in another department, so that, by the time he took his degree, every student should know what the whole college was doing and have had some experience of the difficulty of conveying, in the language of common discourse, ideas familiar to us in the language of special discourse or technical terms. Humanists would learn how to make the language richer and more precise by the accurate use of scientific terms, and scientific men might discover that the King's English is a far more adequate medium even for conveying scientific ideas than they had hitherto supposed.

It is an important contribution to the discharge of the function of a university to see that every student knows something of what the university as a whole is doing and to keep the channels of communication between one mind and another open, and bright and clear; and it must profoundly influence the prospects of graduate employment as well as their employability. But its discharge depends in turn very largely on those questions of academic staff which are causing such serious concern to the University Grants Committee in regard to the maintenance of university standards.

The recruitment of academic staff in sufficient numbers to enable the universities to deal with their wider responsibilities is regarded as one of the most difficult problems confronting them. Apart from the increase in the number of students, there is a general desire to increase the ratio of staff to students, while a third reason for increasing the academic staff is the introduction of new subjects which call for the services of specialized teachers and research workers. No accurate measure has been obtained of the increase in full-time staff which would be required to meet these needs. At a rough guess, the University Grants Committee puts the total of full-time staff required at 10,000 as against a pre-war 4,000, assuming that student expansion on the scale contemplated is achieved by the end of the decennium; but it estimates 8,000 as the maximum that could be expected by the end of the quinquennium, without any firm confidence that this expectation will be realized. It points out that the suspension of normal university activities during the six years of war has left a gap in the production of men and women suitable for appointment as university teachers which will take years to repair. During the war years, moreover, many senior teachers remained at their posts after the normal age of retirement, while many other posts remained unfilled.

Temporarily, there is a demand much in excess of the supply of suitable candidates, and even if there is no further increase in the numbers of students, no marked improvement in the staff–student ratio appears likely during the present quinquennium. The present age-structure of the university staffs in Britain constitutes a further reason for caution. To-day, some fifty per cent are less than thirty-five years of age, and the University Grants Committee suggests that, while the Universities may be able to do little to remove the disproportion, they should attempt to plan future recruitment so as to secure a more uniform distribution over the ages from twenty-five to sixty-five. Furthermore, the reinforcement of staffs is dependent on the physical expansion of the universities, so as to provide conditions in which the staff are no longer handicapped by unsatisfactory environment.

There is no suggestion in the report that the heavy strain under which university staffs in Britain have been working during the last ten years has hindered recruitment; and the University Grants Committee appears to be confident that the marked improvements in the salaries of lecturers are adequate to attract a sufficient flow of candidates of the right type, though it points out that any substantial change in the value of money or in the standard of remuneration in comparable professions would lead to a situation requiring consideration of salary-levels. It lays more stress on the importance of associating the lecturer grades with the administrative work of the University, and of providing the senior members of the staff with secretarial or administrative assistance and with adequate technical assistance in the laboratory. Such means of relieving the senior members of duties which do not demand their personal attention are particularly important while it is difficult to obtain staff of sufficient seniority, and also to enable the universities to continue to give assistance in the development of university institutions in the Colonial territories that is being planned.

This sober review of university development is thus full of encouragement. Like the Nuffield College statement, it hints at the possibility that expansion may have to be re-timed, and that the rate of expansion may need to be modified. But the wide vision and the balance of the report warrant every confidence that the University Grants Committee will prove equal to its new and wider responsibilities, and that the expansion of the universities of Britain will be guided wisely and imaginatively. The Committee clearly intends that academic autonomy and standards shall not be impaired, and that the new opportunities of service to the community should be fully utilized. The contribution of the universities over the whole field of national life can repay increasingly those large appropriations for their support which are now made from the national exchequer.

VITAMINS AND HORMONES

Vitamins and Hormones

Advances in Research and Applications. Vol. 5. Edited by Prof. Robert S. Harris and Prof. Kenneth V. Thimann. Pp. xvi+478. (New York: Academic Press, Inc.; London: H. K. Lewis and Co., Ltd., 1947.) 7.50 dollars.

THE volume under consideration deals with many aspects of vitamins and hormones, and it will certainly be of the very greatest value to anyone involved in research in these particular fields, or who is teaching or preparing a text-book.

The first section, by Nicholas A. Milas, deals with the synthesis of vitamin A and related products. The bibliography is complete up to well into 1947. The article deals very thoroughly with the production of synthetic analogues, and a particularly clear account is given of the work on synthesis by Heilbron and his colleagues, and the relation of this work to that published by the Dutch investigators, Van Dorp and Arens.

It is not possible to review in detail all the sections, and passing over the very full and excellent account by Melnick and Oser of the physiological availability of the vitamins and Von Muralt's summary of the present position of vitamin B_1 in relation to peripheral neurophysiology, we come to William J. Darby's review of the position of pteroylglutamates in relation to human nutrition and disease. Workers in Great Britain and on the Continent of Europe have failed to realize the enormous concentration that has taken place in the United States on this work. Investigation of the extensive metabolic and hæmatological effects of folic acid constitutes only one small part of the work. Very extensive investigations have been made into the effect of folic acid in sprue, chronic diarrhœa, and various diseases of infancy and childhood. This summary will go a long way to prepare the British and Continental reader for the vast amount of work that will be published from now onwards in the journals of the United States. Efficient and excellent as this article is, it can only act as an introduction to this subject, since important questions, such as the anti-folic acid substances and their use in various conditions like leukæmia and in the treatment of malignant disease, are not touched upon.

Then follows a short chapter by H. R. Bird on the vitamin requirements of chicks. It is pointed out that this is important not only in the study of nutrition as a whole but also for "the more efficient and profitable production of this economically important animal". A rather longer chapter, by H. P. Morris, deals with the vitamin requirements of the mouse.

Choh Hao Li and H. M. Evans deal very thoroughly with the properties of the growth and adrenocorticotropic hormones. The methods of assay and of isolation, and the physical, chemical and biological properties of these two hormones are described. Then follows an article by C. W. Emmens and A. S. Parkes on the effect of exogenous œstrogens on the male mammal. This is very valuable in that it collects together the much scattered work on the effect of œstrogens on such varied functions as growth and sex differentiation and on other glands.

The chapter on the biology of antithyroid agents, by H. A. Charipper and A. S. Gordon deals very exhaustively with the effects of thiourea and its derivatives on the structure of the thyroid and pituitary glands in various species, on growth and general metabolism, on iodine metabolism, on enzyme systems, etc. The article also deals with the chemical nature of the antithyroid agents and their clinical applications.

The next chapter, on the use of androgens in women, by Anne C. Carter, E. J. Cohen and E. Shorr, describes the biological effects of androgens in women and their use in the treatment of various disorders.

The final article, by C. G. Heller and W. O. Maddock, deals with the clinical uses of testosterone in the male. The authors indicate the various ways in which hypogonadism can be diagnosed. They indicate the various methods of administration of testosterone, its biological effects and its clinical applications.

By the Staff of the Computation Laboratory. (Annals of the Computation Laboratory of Harvard University, Vols. 7, 8, 9 and 10.) (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1948.) 55*s*. net each volume.

THESE four massive volumes contain a further very substantial instalment of the publication of the great table of the Bessel function $J_n(x)$, for values of x less than 100 and for integer orders n up to 100, which has been computed by means of the automatic sequence controlled calculator in the Computational Laboratory of Harvard University under the direction of Prof. H. Aiken. Previous volumes have been reviewed in these columns (*Nature*, **160**, 773; 1947), and five further volumes will be required to complete the project.

It will be noted that while volumes 7 and 8 (like their immediate predecessors) contain only three functions, volumes 9 and 10 each contain twelve. This is made possible by discontinuing the tabulation of values at intervals 0·001 in x for values of x less than 25, for orders above the fifteenth, and thereafter using a uniform interval 0·01. This will reduce to about three feet the present writer's earlier estimate of the length of bookshelf required to house the complete series. Except perhaps for the smaller values of x (where 10 decimals mean fewer than ten significant figures), it is unlikely that many users will often find inadequate the values within their range which the tables actually give; indeed, the provision is on a munificent scale.

Since the previous review was written, a systematic comparison has been made of values common to the Harvard tables and the tables, now in proof, to be published as "British Association Mathematical Tables", Vol. 10, and no error has been found in the Harvard tables.

In reviewing these volumes one cannot help contrasting the resources enjoyed by our American colleagues with those which have been at the disposal of workers in the same field on the eastern side of the Atlantic. But there is a danger that lavish resources may be wastefully used. The terms of the power series for $J_n(x)$ are numerically the same as those for $I_n(x)$, and an almost similar remark applies to the asymptotic series, including those for $Y_n(x)$ and $K_n(x)$, so that with slight modifications in procedure, and without proportional increase in time or labour, fundamental values for the other three functions over considerable ranges could conceivably have been produced concurrently with those for $J_n(x)$. However, let us be thankful for great mercies!

W. G. BICKLEY

A TEXT-BOOK FOR AGRICULTURAL ECONOMISTS

Farm Management

By Prof. John D. Black, Marion Clawson, Charles R. Sayre and Walter W. Wilcox. Pp. xii + 1073 + 62 plates. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1947.) 27*s.* 6*d.* net.

FARM management as a subject of serious economic study has derived a great deal of stimulus from the United States, especially since the 'country-life movement' was set on foot there some forty years ago. The early workers in that field set out to study the whole social structure of the countryside; but a large part of their attention was necessarily directed to the purely business aspect of farming, and indeed the study of farm management has been in danger all too often of being regarded merely as a means of helping the individual farmer to make more profit. Anyone who is at all familiar with Prof. John D. Black's work on production economics, however, has learnt to expect a more comprehensive outlook, and in this imposing volume that expectation is not disappointed.

Apart from the four main parts of the book which deal, in no fewer than nine hundred pages, with systems of farming, principles and methods of analysis, problems of management, and management of types of farming, there are an introduction and a finale with chapters on such topics as the ends of farming, farming in a changing world, and agriculture in the national economy. These bear on the broader problems concerned with reconciling the interests of farmers with those of society as a whole, and embody much of the practical wisdom accumulated over many years by Prof. Black and his distinguished collaborators.

The student is made to see that modern agriculture does not stand in isolation, and that the management of a farm, if it is to be successful in the long run, should look beyond the immediate profit-and-loss account. This emphasis is to be welcomed in general, though some readers may consider, in this instance, that breadth has been secured at some sacrifice of depth. Certainly the British student, dependent as he largely is on American texts for the application of economic principles to farm management, will find the mass of descriptive material a little distracting, the more so as it relates almost entirely to American conditions. It is also unfortunate that some references to conditions in Great Britain are inconsistent and inaccurate. For example, it appears that if leasing arrangements such as prevail in England and Wales could be developed in the United States, there would be no serious objection to a large increase in tenancy in that country (p. 654); but this is a conclusion scarcely to be expected, perhaps, in view of the statement that in England "the landlord does practically nothing except to receive his rent and occasionally give his consent to having some new buildings or other improvements put on his farm, or possibly to having some timber cut" (p. 13).

Blemishes of this kind—there are a few others—are relatively unimportant against the authors' competent handling of their main project, which is to provide and expound methods for analysing the problems that develop on farms of varying complexity, and the principles which may be evoked for their solution. It is this aspect of the book, rather than the illustrative material, which will be found helpful and which deserves most attention, at any rate in Great Britain. R. N. DIXEY

THOMAS ALVA EDISON

The Diary and Sundry Observations of Thomas Alva Edison

Edited by Dagobert D. Runes. Pp. xii+247+5 plates. (New York: Philosophical Library, Inc., 1948.) 4.75 dollars.

DRIVEN by his deafness to read his way through the Detroit Public Library, Edison wrote long afterwards that he had found that almost any book would supply entertainment or instruction. This book, which contains selected excerpts from his writings, supplies the first in good measure and, for those who reflect on reading, more than a modicum of the second.

The pages from the diary which form the opening section of the book are full of whimsical humour which one would not have expected from a prodding experimenter who died with more than a thousand inventions to his credit. There is little reference in the book to Edison's experimental work, except for a short account of his early struggles to make a motion picture machine, carried out in a studio irreverently called the "Black Maria". But the background is there, revealed in the words that experiments in a laboratory consist mostly in finding out that something will not work. A realization of this, and of the fact that his own education was self-directed, gives added value to the pages on "Education and Work". In these pages he betrays a little impatience with the many for whom, with the passing of childhood, there comes the paralysis of curiosity and atrophy of the power to observe. They are so unlike himself. He remained curious and observant to the end. If a man more than seventy years of age cannot keep occupied, it is because there was lack of interest in a sufficient number of things when he was younger. He announced his intention of having a sign put up all over his plant reading, "There is no expedient to which a man will not resort to avoid the real labour of thinking".

With Edison, thinking led to an intense desire to work and to experiment. "No human being can live long without work", he writes in one of his sundry observations—the pleasure of idleness is one of the great superstitions of the human race.

Edison's observations on the possibilities of atomic energy, his somewhat casual remarks on the influences that make for peace or war and his comments on disarranged economic systems—all these make reading which is the more interesting because of all that has happened since the last of these lines was written. Reading the pages of this book, we feel that here was no recluse, no experimenter shut away in his laboratory from the rest of the world; here was one who was of the people, working for the people. "I consider," he writes, "that the first mission of the motion picture is to make people happy, the second—to educate, elevate and inspire."

This is a book to have on one's shelves and to dip into for five minutes when one feels depressed.

W. G. R.

UNIVERSITY DEVELOPMENT IN GREAT BRITAIN

THE University Grants Committee has always regarded itself fundamentally as a channel of communication between the State and the universities of Great Britain, and before the War this function was expressed mainly in the interpretation to the Government of the policies and financial needs of the universities. The increasing dependence of the universities on Government support makes it equally important that these policies and needs should also be interpreted to the general public. That function is admirably discharged by the present report*, which summarizes conveniently, with diagrams and comparative statistics, the changes that have occurred in what has probably been the most eventful twelve years in the history of most, if not all, of the universities of Great Britain. Although the new terms of reference of the Committee will make it increasingly concerned with the task of assisting the universities to plan their developments on lines that will meet as closely as possible the needs of the community, the new function will never diminish the importance of the old one of interpretation, both to the Government and to the community.

Before discussing post-war developments and problems, which occupy almost three-quarters of the report, the Committee deals briefly, in successive chapters, with the period 1935–39, the war years and with the revival of the universities after the War; and the narrative is illustrated by numerous appendixes which record changes in the membership of the Committee itself since 1936, the membership of the sub-committees constituted to deal with its new functions, university income and expenditure under main heads, capital benefactions and major additions to university buildings for 1946–47 in comparison with 1935–36, total numbers of students for 1938–39 and in the autumn term 1947 and of assisted students. Details are given of the arrangements for the deferment and call-up of university students, the call-up of university staffs for national service and of the war-time location of the University of London, its colleges and schools. Indeed, the report is a well-nigh indispensable reference work on university development in Britain, and the change in format will render its use for such purposes more generally convenient. Publication of the annual statistical volume of Returns from Universities and University Colleges in receipt of Treasury Grant, suspended since 1938–39, is to be resumed with the volume covering the academic year 1947–48.

The three changes recorded in the grant list since the last report in 1936 are the grant by the Privy Council to University College, Nottingham, of a charter of incorporation as a full university, the formal admission of the University Colleges of Leicester and Hull to the grant list, and approval of financial support for the establishment of a new University College at Stoke-on-Trent, subject to the grant of the necessary royal charter and arrangements for effective sponsorship by one or more universities. During the whole period covered by the report, the total income of the universities of Britain was more than doubled, rising from £6,060,995 in 1935–36 to £13,043,541 in 1946–47, the principal increases being £4,803,000 from Parliamentary grants, £1,052,000 from students' fees, £342,000 from endowments and £194,000 from local authorities. The increase in the Exchequer grant came mainly in 1945, and the proportion of the total income of the universities which is derived from the State has now risen from 34·3 per cent in 1935–36 to 52·7 per cent, and by 1951–52 may well be more than 60 per cent.

Before discussing the implications of this development, the report refers to non-recurrent grants and to the acceptance in principle, by the Chancellor of the Exchequer, of the Committee's estimate that the capital needs of the universities for the quinquennium 1947–52 would amount to some £40,000,000 for new building and £10,000,000 for site and equipment, of which by far the greater part would have to be found, if at all, by the Exchequer. At the same time, the Chancellor indicated that in view of unavoidable restrictions on new construction, it was unlikely that more than £20,000,000 of building work would be possible in the quinquennium, and subsequent deterioration in the building situation makes it very doubtful whether even this estimate can be fulfilled. Nevertheless, capital benefactions received by the universities during the twelve years under review amounted to £14,366,872, of which £5,996,636 was for the erection of new buildings or the acquisition of land and properties, £6,798,794 for endowments and £1,571,442 for the establishment of fellowships, scholarships and prizes. During the years 1935–36 to 1944–45, approximately £6,700,000 was expended by the universities on the erection of new buildings and purchase of properties, chiefly before the War. Total expenditure in 1946–47 was £12,951,071 as against £6,141,401 in 1935–36.

The quinquennial system of assessing grants was re-introduced in 1947, and by 1951–52 the contribution from the Exchequer to recurrent university purposes will have risen to about £13,000,000. The new and enlarged conception of the responsibility of the State in the field of university education has caused the Committee to reconsider seriously the principles which should govern the distribution among the universities of the money at its disposal. It considers its function to be not direction, but stimulation, co-ordination and advice; consequently, although the Committee has earmarked certain grants for special fields of study for reasons of national policy, it regards this device as unsuitable for permanent adoption because it impairs to some extent the universities' freedom of action. This principle of directing public money most freely into the channels in which it seems likely to produce the most fruitful results—a policy of helping those who help themselves—unlike the obvious criteria of need, is one that may favour the senior universities and those modern universities which have received the largest measure of support. Endowment income in 1946–47 still remained at 9·3 per cent over Great Britain as a whole but varied widely among the universities, averaging, for example, only 3·1 per cent in the University of Wales as against 10 per cent for those of Scotland.

---

* University Development from 1935 to 1947. Being the Report of the University Grants Committee. Pp. 106. (London: H.M. Stationery Office, 1948.) 2*s*. net.

The report shows that the University Grants Committee is well aware of the difficulties which may arise in reconciling the claims of achievement with those of need, and it cites professional salaries as a pertinent example. The report details the reasons which led the Committee to recognize variations in such salaries as a permanent feature of university finance in Britain. The Committee finally decided to compromise on a plan which reduced the existing inequalities and recognized for all institutions a standard rate of professional salary, and assessed for each institution a sum which in the Committee's view might properly be expended in raising the salaries of some professors above the standard rate. While the factors to be taken into account in determining this assessment are indicated, the Committee did not seek to determine or to suggest the salary to be paid to a particular professor, and the arrangement is believed to have been accepted by the universities generally as a reasonable settlement.

That example itself indicates something of the character of the new and intricate relationship between the State and the universities which it is a main purpose of the report to illustrate. Moreover, the Committee regards as one of its most important functions that of devising appropriate means of reconciling the central planning of university developments with the maintenance of the essential academic freedoms. The need for some form of central planning is well recognized by the universities themselves, and the Committee believes that such planning is not irreconcilable with academic autonomy. It believes that the duty of ensuring that the large grants from the Exchequer are expended in the way best calculated to promote the public welfare can be discharged by the Committee in a relationship between the State and the universities which may properly be conceived as a form of partnership. Indeed, it suggests that the most serious threats to academic autonomy in Great Britain come rather from other external sources, such as benefactions accompanied by restrictive conditions, or from factors which in devious ways diminish the vigour of academic life.

The full extent of university dependence to-day on Government support is revealed not only in the financial sections of the report just outlined. It is further shown in the section of the report which deals with the number of students. After the fall in numbers during the War from 50,000 to 35,500 in 1943–44, largely in the faculty of arts, where the number of men students fell from nearly 15,000 to about 3,500, by October 1947 numbers had risen again to 77,000, and estimates received from the universities by the Committee indicate that by the end of ten years they expect to be able to deal with 88,000 students, or only 2,000 short of the total figure required to meet the recommendations of the Barlow Committee on Scientific Man-power. Expansion has been greater than expected in the Universities of Oxford and Cambridge and in many of the London colleges, but has been mainly in the provincial universities. Pre-war numbers in science and technology have been approximately doubled, but numbers in the faculties of arts have only risen by 50 per cent, and the Committee considers that it is unlikely that additional students in arts will be forthcoming to bring the number up to 10,000. For some years to come the proportion of students engaged in scientific and technological studies is likely to be higher than it was before the War.

The Committee suggests that this ratio should be kept in mind; but it is more concerned with the question of quality, both of students and of academic standards. Little direct evidence is yet available of the capacity of the schools to provide a largely increased supply of freshmen of the quality necessary for a university career, and the report emphasizes that more than a third of the students at present in the universities are receiving grants under the Further Education and Training Scheme. While this scheme is temporary, the percentage of full-time students receiving assistance in some form or other from public funds had risen in 1946–47 to 67·9 as compared with 41·1 in 1935–36, and the University Grants Committee believes that if the present number of students in the universities is to be maintained, still more if it is to be exceeded, subsidies on an unprecedented scale will be needed. The report briefly reviews the new problem of selection which these conditions present, starting with the assumption that the universities must not be deprived of an effective choice of their own entrants; its observations should be carefully noted in considering the recommendations of the Working Party on University Awards which have since been published.

Next, however, the report considers the bearing of the quality of the life and education which the universities are able to provide and the maintenance of university standards. The effect of the war years on those standards is reviewed in an early chapter; while there were certain imponderable gains, the balance was heavily on the debit side. Now the rapid increase in the number of students has imposed heavy strains on staff and students alike, which in some respects have involved serious deterioration in the standards of university life. The Committee is convinced that unless additional accommodation can be speedily provided, the present student numbers cannot be maintained without grave risk of impairing, not only academic standards which can be measured directly by examination results, but also those imponderable elements which form so valuable a part of university life. To quote the report:

"Unless there are considerable additions to accommodation, some universities will not be able to increase their staffs further. Moreover, a number of universities find themselves unable to make the fullest use of their existing staff owing to lack of accommodation for discussion groups and individual tuition. In some universities there is no room in Union or Library for a large proportion of the students; the present shortage of books adds further to the pressure on the libraries. At many universities there are, every day, long queues waiting for places in refectories which, even though enlarged considerably since the war, are quite inadequate for present numbers. A leisured university life with adequate opportunities for regular contacts between staff and students is rarely possible."

Elsewhere in the report the Committee states that there are no universities in Britain in which the provision of large new teaching blocks is not a pressing necessity, and that both teaching and research are seriously hampered by lack of space. Nevertheless, while stressing the vital importance of sufficient private rooms for staff and of taking a broad and imaginative view of the future in planning new libraries or extensions of the libraries, the Committee endorses the view that the further provision of halls of residence should be a primary object of university policy during the next decade, in spite of the difficulties of implementing such a policy at present. In many universities the greatest contribution which can be made to student life at this time is the increased provision of central amenities.

Apart from the physical aspects of university expansion and their bearing on the maintenance of university standards, the University Grants Committee is seriously concerned with the staff conditions. Reference has already been made to over-work and lack of leisure; and the point is reiterated in respect of the research worker, whose most elementary need, coming before even that of suitable equipment for research, is that of sufficient leisure from the pressure of other duties. In regard to research equipment, the Committee incidentally again refers to the importance of library expansion, and looks for some improvement in the facilities for the publication of learned works. One of the principal and most difficult problems confronting the universities is that of recruiting academic staff in sufficient numbers for the discharge of their wider responsibilities. Apart from the increase in the student population, in the spring of 1944 only 68 per cent of the holders of full-time teaching posts on normal establishments remained, 78 per cent of senior administrative and 57 per cent of library staffs. Altogether, some 1,380 members were absent in the Forces or on some form of national service. Furthermore, there is now a call for an increase in the ratio of staff to students, partly to permit students to receive much more individual tuition and partly to free more time for research. With the demand for specialized teachers and research workers arising out of the introduction of new subjects, the Committee estimates that the numbers of full-time staff should be increased during the decennium from the pre-war figure of 4,000 to not less than 10,000. By 1946–47 the number had risen to more than 5,500; but the maximum to be expected by the end of the quinquennium is estimated at 8,000. Questions of salary are discussed in some detail, and the report urges that all universities should review their administrative arrangements with the object of relieving their professors and heads of departments of any duties that do not necessarily demand their personal attention, and also that means should be found of enabling a larger proportion of lecturers to participate more directly in the administrative business of the university.

The report deals very briefly with such general academic problems as the place of research, curricula and teaching methods; but a section discusses a number of specific problems, mostly arising out of Government reports such as those of the Goodenough Committee, the Loveday Committee on Higher Agricultural Education, the Scarborough Committee and the Clapham Committee. The University Grants Committee has itself appointed a separate sub-committee to deal with technology, which will consider the recommendations of the Percy Report; but the work of this Committee falls outside the period of the present report. Finally, the extra-mural work of the universities is reviewed. The majority of the Committee believes that the universities are making and should continue increasingly to make a unique and indispensable contribution to adult education, but that their special function is to foster and intensify study by all means in their power, and to maintain a high standard of qualitative achievement among those engaged in it. The dissipation of resources should be avoided by wise discrimination.

PROBLEMS OF ORGANIC GROWTH

By Prof. LUDWIG von BERTALANFFY
Zoologisches Institut, University of Vienna, and
Middlesex Hospital Medical School, London

ORGANIC growth is, without doubt, one of the basic biological phenomena. Physiology presents a wide realm of experiences concerning factors influencing growth; however, the phenomenon of growth itself remains, as yet, unexplained. Many growth formulæ have been proposed, but none has been generally accepted. Recent investigations, however, seem to provide a consistent theory leading to an explanation of growth in its general course as well as in its specific peculiarities, to quantitative laws allowing calculation and prediction, and towards a unification of the great physiological realms of metabolism, growth and form development[1].

Animal growth may be considered a result of the counteraction of synthesis and destruction: anabolism and catabolism of the building materials of the body. There is growth so long as building up prevails over breaking down; the organism becomes stationary if and when both processes are equal. This may be expressed in a general formula which contains no hypothetical elements:

$$\frac{dy}{dt} = \eta y^n - \varkappa y^m.$$

In words: the change in body weight y is given by the difference between synthesis and destruction of building materials; according to general physiological experience, these processes will be proportional to some powers, n, m, respectively, of the body weight; η and $\varkappa$ are constants of anabolism and catabolism.

To make use of this consideration, the processes involved must be defined. Catabolism is represented by the continuous loss of building material, and corresponds, in the higher animal, to what is called *Abnützungsquote*, or quota of wearing out (Rubner). Physiological experience shows that it is, to a good approximation, proportional to body-weight, so that the exponent m can be made equal to 1.

With respect to anabolism, a number of different cases can be distinguished. A survey of the types known hitherto is given in the accompanying table.

In micro-organisms[2], the character of the growth curves depends simply on the geometrical shape. In the case of spherical forms (yeast, micrococci) where the ratio of surface to volume decreases with increasing size, we find a decrease of growth-rates; on the other hand, rod-shaped forms (bacteria) which grow almost exclusively in length and where, therefore, the surface–volume ratio remains almost constant, show simple exponential growth. The fact that the surface where the intake of material takes place is a regulating factor of growth also in lower animals was demonstrated quantitatively in planarians by *measurements of the intestinal tract*[3]. The most interesting case is, however, growth in multicellular animals.

One of the classical problems of physiology is the dependence of basal metabolism upon body-size.

METABOLIC TYPES AND GROWTH TYPES

A. Anabolic processes depend on resorption (*resorbing surfaces*). (*a*) Micro-organisms: (1) Proportional growth: linear and volume growth curve as *B* I; spherical bacteria, yeast. (2) Growth almost exclusively in length: linear and volume growth curves exponential; rod-like bacteria. (*b*) Probably turbellarians.

B. Anabolic processes depend on respiration.

Metabolic type	Growth type	Examples
I. Respiration *surface proportional*	(*a*) Linear growth curve: attaining *without inflexion* a steady state. (*b*) Weight growth curve: *sigmoid*, attaining, with inflexion at *c.* 1/3 of final weight, a steady state	Lamellibranchs, fish, mammals
II. Respiration *weight proportional*	Linear and weight growth curves *exponential*, no steady state attained, but growth intercepted by metamorphosis or seasonal cycles	Insect larvæ, Orthoptera, Helicidæ
III. Respiration *intermediate between surface and weight proportionality*	(*a*) Linear growth curve: attaining *with inflexion* a steady state. (*b*) Weight growth curve: *sigmoid*, similar to I (*b*)	Planorbidæ

The fundamental formulation is the well-known *surface rule* of Rubner stating that in warm-blooded vertebrates basal metabolism, as measured by oxygen consumption, carbon dioxide or heat production, is a function not of weight but of surface. It is well known that this rule has been explained by Rubner through the exigencies of homeothermy. Later research[4], and especially a series of investigations carried through in our laboratory[5], has, however, demonstrated two important facts. First, the surface rule holds good also for many poikilothermous animals, vertebrates and invertebrates, so that the rule is of wide application; but the explanation given by Rubner is too restricted. On the other hand, there are also other modes of dependence of metabolism on body-size. Therefore, we arrived at the statement of *metabolic types* in respect of the relation between respiration and body-size.

Just as there are several metabolic types, there are also different *growth types*, distinguishing themselves by different growth-curves. We succeeded in establishing a connexion between metabolic types and growth types, providing an explanation and quantitative laws, and leading to the foundation of a comparative physiology of growth.

Investigation has shown that respiration is to be considered a limiting factor of anabolism of building materials. Inserting into the basic equation that value of n which is found experimentally for size-dependence of respiration, the growth laws of the organism in question follow automatically. It is possible, therefore, to *predict* the growth type of an animal from its metabolic type. This 'forecast' was confirmed in all cases hitherto investigated, sometimes leading to completely unexpected results. This system of growth laws has been applied to a considerable number of growth curves, including micro-organisms, tissue cultures, crustaceans, lamellibranchs, snails, hemimetabolic and holometabolic insects, fish, mammals, man, regenerative growth, etc., giving good numerical agreement in all well-investigated cases.

Since the constant $\varkappa$ of the growth equation represents the wearing-out quota, the values of $\varkappa$ as calculated from the growth curves should be identical with the values of protein catabolism, as measured by physiological experiment. In fact, the calculated values have been confirmed in a number of cases, including lamellibranchs, crustaceans, fish, man. This is, however, not true for small mammals: here the calculated values are considerably higher than those determined by the classical physiological methods, namely, determination of nitrogen excretion or protein loss in the starving animal. It was inferred, therefore, that the usual methods give values which are too low and that, in fact, protein metabolism goes on much faster than formerly assumed[6]. But this is just the conclusion which is reached by the modern method of isotope tracers[7]. It appears, therefore, that a combination of these two methods, namely, determination of protein metabolism by isotope tracers, and its calculation from the growth curves, should lead to important insights into this field of metabolism.

Very interesting are the connexions between *sex, metabolism*, and *growth*. Take, for example, a species showing remarkable sexual dimorphism in respect to growth and size, like the cyprinodont fish *Lebistes reticulatus*. Calculation of the growth curves shows that the ratio of the anabolic constants η in females and males is about $1 : 1\frac{1}{2}$. Theory demands that the same ratio should hold for respiration—and this is found to be the case.

Further application of the theory has been made in respect of environmental growth factors, as, for example, the *dependence of growth on temperature*, which partly coincides with Bergmann's rule in ecology. This leads to the conclusion that, while the growth curve is steeper at higher temperatures, a larger final size is reached at lower temperatures. This result corresponds to the observed data. The methods yielded by the theory can be applied also to the analysis of *geographical variation*, and should be useful for applied biology (fisheries, investigation of nutritional factors, etc.)[8].

So far, the quantitative analysis of growth and the establishment of growth laws consisted only in attempts to fit a number of growth curves to some formula. A rather scattered set of points as is given in observed growth data may very well be approximated, however, by quite different mathematical functions which, therefore, tell nothing about the underlying mechanism. Satisfactory approximation is a necessary, but by no means sufficient, condition, so that we may attach to a mathematical function a rational, as opposed to a merely descriptive, significance. The theory outlined above is of a different character; consequences can and have been deduced from it which can be tested by independent experiment; in some cases predictions have been later verified by experiment in a most surprising way.

The growth theory outlined here is part of a wider theoretical consideration, namely, the conception of the organism as an '*open system*', exchanging materials with its environment and approaching, in general, a steady state[9]. We cannot consider this point of view here, and may mention only that therefrom follows the *equifinality* of growth, that is, the fact that the same final state may be reached from different initial sizes (for example, individuals with different birth-weight in litters of different number) or after temporary suppression of growth (for example, by temporary undernutrition or vitamin deficiency). Also the *rule of constant cell size* is a consequence of the equifinality of growth. The concept of open systems has also been applied to the *biological elementary units*, viruses, genes, and chromosomes[10], and a physical model has been indicated[11]. According to these considerations, self-duplication in viruses and genes results from the fact that they are 'metabolizing aperiodical crystals'. At least in respect of chromosomes, this conception appears to be well founded since tracer investigation has shown that the nucleoproteins of the cell are continuously worn out and replaced[12].

Further investigations have been made in respect of *relative growth*. Allometry is a valuable tool in the investigation of metabolism[13]. In fact, the older disputes on the bearing of the surface rule have been caused largely by the fact that only arithmetical methods, and not allometric plots, have been applied. The latter has been done in more recent investigations, leading to our distinction of metabolic types, as mentioned above.

Another interesting phenomenon is the dependence of *physiological rhythms*, such as pulse and respiration frequency, on body-size[14]. According to the general principle that, roughly speaking, metabolism is relatively higher in small, as compared with big animals, pulse- and respiratory-rates decrease with increasing size. Quantitative analysis starting from the surface relation of basal metabolism, and taking into account the allometries of heart-size and beat-volume, leads to a rather remarkable result. The theoretical allometry of pulse-rate deduced from the factors mentioned corresponds astonishingly well with empirical data in a vast range of seven orders of magnitude, from the dwarf bat weighing 4 gm., with a pulse-rate of about 1,000 per min., to the elephant weighing 2,000 kgm., with a pulse-rate of 25 per min. Since in this deduction very crude approximations have been made, and anatomical, physiological and ecological peculiarities of the animals in question have been neglected, this result shows that simple size-dependence is the governing factor of pulse-rate. Similar conclusions apply to respiratory frequencies.

According to Huxley[15], we find in organisms and organs growth gradients which can be defined by the allometry constants of the different regions. On the other hand, there are, according to Child[16], 'physiological' gradients manifesting themselves in differences of susceptibility, metabolism, and morphogenetic activity. The connexion between growth gradients (Huxley) and physiological gradients (Child) is an important but hitherto uninvestigated problem. We have studied it in the classical object, namely, planarians, in order (1) to establish the relation between the different kinds of gradients; (2) to test Child's gradients in a quantitative way; and (3) to establish quantitative laws of toxic action[17].

The results have been rather fatal for Child's theory. In planarians, no connexion between growth and 'physiological' gradients can be found. Further, a quantitative analysis shows that even a primitive organism like a planarian is not characterized by a single axial gradient; but shows rather a bundle of axial gradations in respect of different physiological phenomena. These investigations have been continued in an extensive study of the toxic action of a group of substances of pharmacological interest, namely, the quinones. With respect to the gradient problem, different toxic actions have been distinguished and, as a new result, complete 'gradient inversion' was found, corresponding to definite molar concentrations.

Simultaneously, the *quantitative laws of toxic action* have been studied. The effect of concentration follows the equation $tc^a = b$ (t = time, c = concentration, a and b = constants), which is known also in other pharmacological reactions[18], and can be considered, from the physico-chemical point of view, as an adsorption isotherm, from the biological, as an application of allometry to pharmacological action.

Further, a *unification of the theory of growth in time and of relative growth* has been attempted[19]. These derivations lead to expressions which describe time-growth of organs without introducing new constants besides those of total growth and of allometry. Some consequences of this theory are that growth curves of linear dimensions should have no inflexion in organs of negative allometry and isometry, but should be sigmoid in the case of positive allometry; that in undernutrition organs of positive allometry should increase at the cost of others; that in starving animals organs showing positive allometry should decrease faster than those showing negative allometry or isometry, etc.

The conception of organic growth outlined here leads to important conclusions in respect of basic problems of evolution, such as orthogenesis, phylogenetical laws, bearing of selectionistic interpretations, role of hormonal changes, peculiarities of the descent of man, etc.[20]. Without entering into details, the relation to recent phylogenetic theory may be mentioned[21]. Thus, a vast range of problems, extending from physico-chemistry to physiology and morphological questions, is approached in this conception.

AUREOMYCIN, A NEW ANTIBIOTIC

A VERY important series of sixteen papers on aureomycin has been published in the *Annals of the New York Academy of Sciences*, vol. 51, Art. 2, pp. 175–342 (November 30, 1948). These papers were the result of a conference on aureomycin held by the Division of Mycology of the Section of Biology, the New York Academy of Sciences, on July 21, 1948. They represent the work of forty-three investigators, sixteen of whom are on the scientific staff of the Lederle Laboratories Division, American Cyanamid Company, Pearl River, N.Y. The remainder are well known and independent biological and medical research workers in official laboratories, university medical schools and hospitals, all of whom were supplied with aureomycin by the Lederle Laboratories.

In the introductory paper, B. M. Duggar, of the Lederle Laboratories, traces the history of the discovery of the new antibiotic, and pays tribute to his late colleague, Dr. Y. SubbaRow, who directed the work until his death. Aureomycin, which has been obtained as a highly purified, crystalline, faintly golden-yellow substance, is a metabolic product of *Streptomyces aureofaciens*, a hitherto undescribed species of the Actinomycetes. Hence its name, and not, as a London evening newspaper has recently stated, "because it can be given by the mouth". It has clearly been made in considerable quantities—fermentation in tanks is mentioned—but few details are given of the methods used for the production and isolation of aureomycin, and chemists will look in vain for any information as to its chemical nature, except what can be gleaned from the fact that a hydrochloride and a borate are referred to. To avoid confusion, mention should be made of the fact that the trade mark 'Duomycin' has been given to aureomycin.

In vitro bacteriological studies of aureomycin, carried out in the Division of Penicillin Control and Immunology, Food and Drug Administration, Washington, in Johns Hopkins University School of Medicine and in Boston City Hospital and Harvard University Medical School, have established that aureomycin is effective against both Gram-negative and Gram-positive bacteria. Higher concentrations of the substance are required to produce bacteriostasis than are necessary with penicillin, being close to those required of streptomycin. Bacteria do not readily become resistant to it *in vitro*. It seems to be rather unstable in aqueous solution even at room temperature, though the dry solid material appears to be quite stable. An exhaustive study of the pharmacology of aureomycin, carried out in the Lederle Laboratories and at Johns Hopkins, established that it has a low toxicity and almost no side reactions, particularly in solutions of pH 8·5.

P. A. Little, in the Lederle Laboratories, found aureomycin effective in experimental infections in mice of *Eberthella typhosa*, *Erysipelothrix rhusiopathiæ*, the causative agent of swine erysipelas, and also in chickens infected with the causative agents of fowl cholera and fowl typhoid. On the other hand, workers at Johns Hopkins failed to protect mice with aureomycin administered orally in experimental infections with *Pneumococcus* type I or *K. pneumoniæ* A., although it did protect against *Streptococcus hemolyticus* beta, and Dr. Henry Welch and his colleagues at the Food and Drug Administration, Washington, conclude that "no outstanding usefulness for this antibiotic has been demonstrated by our animal investigations against the bacteria studied. The greatest promise for the drug lies in the treatment of certain viral and rickettsial diseases."

In spite of the not altogether favourable laboratory findings, clinical trials of aureomycin in human patients have given very promising results. About a hundred patients with a variety of bacterial infections have been treated with aureomycin by mouth at the Boston City Hospital. The results obtained in cases of gonorrhœa, while indicating that this treatment was effective in many cases, were inferior to those obtained with adequate amounts of penicillin. Four patients with pneumococcal pneumonia were successfully treated with aureomycin by mouth. In a number of urinary tract infections the results were favourable, and may be comparable with or possibly superior to those obtained from the use of streptomycin in similar cases. In contrast to streptomycin, there was no evidence of the development of bacterial resistance to aureomycin *in vivo*. Infections with *Proteus vulgaris* and *Pseudomonas aeruginosa* were not benefited by aureomycin. The results in the cases of typhoid fever and of severe *Salmonella* infections were equivocal. Workers in the George Washington University Medical Departments also failed to obtain any clinical or bacteriological response in four patients with typhoid fever. The results obtained by workers at Johns Hopkins in four cases of primary atypical pneumonia were very similar to those of the Boston workers. Eight cases of chronic urinary tract infection, which had not responded to penicillin, streptomycin or sulphonamide therapy, cleared promptly with aureomycin. A. E. Braley and M. Sanders, of the Department of Ophthalmology, College of Physicians and Surgeons, Columbia University, New York, report favourably on results with aureomycin borate used locally and aureomycin hydrochloride used intramuscularly in two hundred patients with a wide range of ocular infections, and found the antibiotic to be effective against some of the Gram-positive cocci and several Gram-negative bacilli. It was also found to be an effective therapeutic agent in the virus infections, inclusion conjunctivitis and herpes simplex of the cornea.

Indeed, even more striking than the antibacterial activities of aureomycin are its effects on viruses and rickettsiæ. S. C. Wong and H. R. Cox, of the Lederle Laboratories, have shown that although it has no apparent *in vitro* activity, it has marked therapeutic activity against the viruses of the psittacosis-lymphogranuloma group and rickettsiæ of the spotted fever, typhus fever, scrub typhus fever and *Q* fever groups in embryonated hens' eggs, mice and guinea pigs. On the other hand, it failed to show any therapeutic activity against a number of other viral infections, notably the *B* strain of influenza, canine distemper and the *MEF*-1 strain of poliomyelitis. Investigators in the rickettsial research laboratory of the University of Texas report favourable results in the treatment of guinea pigs infected with spotted fever and epidemic typhus. Clinical trials of aureomycin in human patients suffering from four different types of viral or rickettsial infections have given very promising results. A group of workers at Johns Hopkins and other investigators in the George Washington University Medical Departments obtained quite dramatic cures in a total of twenty-one cases of Rocky Mountain spotted fever treated with oral aureomycin. Workers in the Harlem Hospital and Columbia University, New York, treated a total of thirty-five cases of lymphogranuloma venereum, usually by intramuscular injection, and conclude from the excellent results they obtained that aureomycin is the treatment of choice in this virus infection. They also found that the ulcerative lesions in three patients with proved granuloma inguinale were healed by the use of this antibiotic. Finally, fifteen *Q* fever patients were treated with oral aureomycin by a group of Californian workers. In fourteen patients improvement occurred relatively promptly after commencement of the therapy, and the investigators conclude that oral aureomycin therapy offers considerable promise in the treatment of this fever.

Although it may be unwise to do so, one is tempted to try to assess the probable future importance of aureomycin in relation to three other antibiotics of proved clinical importance, namely, penicillin, streptomycin and chloromycetin from *Streptomyces venezuelæ*. In the treatment of most Gram-positive bacterial infections, the supreme position of penicillin remains unchallenged. Streptomycin appears to hold a similar though less exalted position in the treatment of many tubercular infections; but it seems probable that aureomycin may displace streptomycin in the treatment of many Gram-negative infections, particularly of the urinary tract, because of the unquestioned advantage it possesses that bacteria do not become resistant to it *in vivo* as they often do to streptomycin. In the treatment of viral and rickettsial diseases, both chloromycetin and aureomycin offer considerable grounds for hope in infections which have so far proved very resistant to chemotherapeutic agents. Whether these two antibiotics will prove to be competitive with, or supplementary to, each other only the future can tell. In the meantime, British investigators will wish to congratulate their American colleagues in the Lederle Laboratories on a very noteworthy achievement. HAROLD RAISTRICK

POST-GLACIAL CLIMATIC CHANGE

A WELL-ATTENDED joint meeting of the Royal Meteorological and Royal Astronomical Societies on December 15 discussed recent work on changes of climate since the Ice Age. The discussion was opened by Mr. F. Hoyle, who said that any persistent change in the temperature of the earth's surface must depend ultimately on radiation from the sun. Without some external cause, solar radiation would not change appreciably in many millions of years, neither would the mean distance of the earth from the sun. But the sun travels through a gaseous medium which is aggregated locally into clouds, and in passing through such a cloud it would sweep up a number of particles. The kinetic energy of these, falling into the sun, is converted into heat, which might increase total solar radiation by as much as ten per cent. All this excess energy appears in the ultra-violet part of the spectrum, but as the latter normally forms only one ten-thousandth part of the solar radiation, passage through a cloud would magnify the ultra-violet many times. This radiation is absorbed in the higher levels of the atmosphere and might alter its whole behaviour, causing great changes of climate.

The strongest evidence for post-glacial changes of climate is biological, and Prof. H. Godwin described the analysis of frequencies of pollen grains. These show the successive incoming of birch, pine and hazel, elm, oak, lime and alder, indicating a progressive amelioration of climate. The sudden expansion of alder and lime about 6000 B.C. marked the beginning of the Post-glacial Climatic Optimum, a warm period which continued until about 3000 B.C., after which the climate again deteriorated. There was a rather sudden worsening about 500 B.C., with flooding horizons and other evidence of increased rainfall. But the interpretation of biological evidence is sometimes difficult. It depends mostly on the present range of the species; but the regional range may be confused with what Prof. Godwin termed the 'microclimatic range', which allowed of local occurrences in exceptionally favoured spots outside the main range.

Prof. Godwin gave an interesting example of a new technique in the analysis of floras, in the climatic control of holly, ivy and mistletoe. A number of meteorological stations are selected and the performance of nearby plants noted—whether they bear ripe fruit regularly, occasionally or never, or whether the plant is not found in the district. These are plotted on diagrams against the mean temperatures of the warmest and coldest months. In this way the 'thermosphere' of each species is defined. Holly and ivy are controlled by the winter temperature, mistletoe by the summer temperature. Prof. Godwin illustrated a region in which the two former are at present flourishing, while mistletoe does not ripen its fruits (mild winters, cool summers). In the Sub-boreal, ivy and mistletoe flourished but not holly (cold winters, hot summers). During the Climatic Optimum, however, all three plants ripened their fruits, indicating mild winters and warm summers.

Climatic changes in the historic period were described by Prof. Gordon Manley, who compared long instrumental records of temperature with advances and retreats of glaciers. The greatest post-glacial expansion of glaciers began in Scandinavia so late as 1750, in the Alps about 1550 and in Iceland probably as early as 1350. Glaciers are now everywhere in rapid retreat, and in Norway archæological remains have been uncovered dating from 1300. Long records of temperature have been carried well back into the eighteenth century at Stockholm, in Holland, and by Prof. Gordon Manley himself in Lancashire. There are difficulties of exposure and of local change of climate due to urbanization, but the general agreement is sufficient to show that the major oscillations are real. The principal feature has been a rise of winter temperature while the summer temperature has maintained a generally constant level; the annual range has everywhere decreased. The temperature records fit in very well with the records of glaciers; in particular, the chilly springs about 1740, which were general and in places catastrophic, decreased the ablation period for glaciers and were followed by glacial advances.

Prof. Gordon Manley then discussed possible causes. Dr. Ångstrom considered that periods of maritime climate were due to increases of the atmospheric circulation, but this only carries the problem back one stage. Moreover, the great fall of temperature about 500 B.C. requires some other factor, and this may be found in the spread of Arctic ice and melt-water. Low spring temperatures result from the frequent inflow of polar maritime air; mild winters with little frost are associated with maritime tropical air, and resemble the conditions in the

Climatic Optimum. It is probable that the changes from year to year due to changes in the circulation are of the same order of magnitude as the average changes between the different post-glacial periods, and the problem now becomes that of finding out why such conditions persisted through decades or centuries instead of only for a year or two at a time.

Dr. C. E. P. Brooks said that the extreme climate, with cold winters and hot summers, which followed the retreat of the ice, could reasonably be put down to the combination of a greater inclination of the earth's axis and the fact that the earth was only just passing out of the condition in which the northern hemisphere was in aphelion in winter. The Climatic Optimum, which was not only mild but also seems to have been on the whole a period of greater rainfall than the present, required some other explanation. The highest temperatures preceded the maximum submergence of the Litorina Sea in Scandinavia; moreover, such a local cause could not explain a change over the whole hemisphere. He thought that the most likely cause was an increase of solar radiation, and he asked whether this could have been brought about by a cosmic cloud. Later, Prof. E. A. Milne and Mr. Hoyle replied that there could not be clouds small enough to cause changes of only a few hundred years, and, though there may be changes of density within a cloud, astronomical theory cannot be tied up with recent climatic changes.

The period which comes at the end of the Climatic Optimum had a peculiar, very extreme climate. Botanists thought that there were alternating contrasted periods of heavy rainfall and drought; at the end, from about 800 or 700 B.C. until 500 B.C., was a 'dry heat wave', after which the climate became very wet and stormy. Such oscillations must be due to changes in the frequency and tracks of depressions, and these might result either from changes of solar activity as indicated by the frequency of sunspots and auroras, or from changes in the outflow of Arctic ice into the Atlantic. The curve of solar activity cannot be traced with any reliability before A.D. 1000, and though there is some resemblance to the variations of rainfall, this is not very close. Dr. Brooks then referred to a theory put forward by O. Pettersson in 1914 that changes of climate since about 3500 B.C. were due to variations in the tides, and particularly in the submarine tides at the boundary of the Atlantic and Arctic. Tidal maxima occurred about 3500 B.C., 1900 B.C., 250 B.C. and A.D. 1433, and about these dates the Arctic ice-cap would tend to be broken up and much ice drift out into the Atlantic. These maxima agreed very well with the periods of maximum rainfall in the northern hemisphere, derived from peat bogs, levels of lakes and rivers, migrations and documentary evidence. He thought that after the Climatic Optimum, before the Arctic ice-cap had firmly re-established itself, the changes of climate resulting from changes in the ice would be very large. With regard to minor oscillations of the order of a decade, he asked if they must have a cause. Could they not just happen, as variations happen in any random series of events?

Mr. D. J. Schove described recent documentary evidence from China, which pointed to great droughts in the third and fourth centuries A.D., floods in the eleventh and drought in the twelfth. He remarked that in Europe the first half of the sixteenth century was very similar to the first half of the twentieth, but about 1540 there was a sudden change to good summers and cold winters. Other speakers mentioned the possibility of causes such as the disappearance of seaweed in the Sargasso Sea and the occurrence of great volcanic activity, for example, in the Rift Valley of Africa. Prof. P. A. Sheppard remarked on the tendency to look for the causes of climatic change everywhere but in the atmosphere, which goes through quite considerable swings not inspired directly by the sun. Although these are generally short-lived, they may be slowed down by the influence of a snow-cover, which may cause long-period variations.

The discussion showed that the various lines of attack on the problem of climatic change are beginning to converge. Our knowledge of the succession of events is becoming very detailed, and the meteorology of climatic change is becoming clearer; but there is not yet any general agreement on the causes. Variations of solar radiation are fundamental, however, and the problem is not likely to be finally solved until these have, in one way or another, been elucidated.

OBITUARIES

Prof. J. H. Maclagan Wedderburn, F.R.S.

Joseph Henry Maclagan Wedderburn, emeritus professor of mathematics, Princeton University, died at his home in Princeton on October 9, 1948, at the age of sixty-six.

Prof. Wedderburn was born at Forfar in 1882 and educated in Edinburgh, where he graduated in 1903. While still an undergraduate, he was elected in 1902 to membership of the Edinburgh Mathematical Society, and soon afterwards, in 1903, to fellowship of the Royal Society of Edinburgh, which later, in 1921, awarded him the Makdougall-Brisbane Prize for his researches into hypercomplex numbers. He obtained the degree of D.Sc. of the University of Edinburgh in 1908. During 1905–9 he was assistant to Prof. George Chrystal, and is remembered as introducing the course in general analysis; but the natural bent of his mind was towards abstract algebra. This interest had been fostered by postgraduate residence in Leipzig, Berlin and Chicago, especially the last, where his mentors, E. H. Moore and L. E. Dickson, were to him a help and permanent inspiration. His first papers on modern algebra were published in 1905 in the *Transactions of the American Mathematical Society*. At the age of twenty-five he had acquired a mastery of the structure of algebras and had made a classical contribution to the theory of semi-simple algebras.

In 1909 Wedderburn left Edinburgh and joined the faculty of mathematics at Princeton University. The First World War interrupted his career for five years. He served in the Seaforth Highlanders, later in command of an observation group in the Royal Engineers, and was mentioned in dispatches. It is characteristic of his unassuming disposition that he had enlisted as a private.

Returning to Princeton, Wedderburn was assistant professor of mathematics during 1921–23, then associate professor until 1928, and finally full professor until he retired in 1945. In 1933 he was elected a fellow of the Royal Society. He never married, and was accustomed to spend his vacations in a remote farm in the Adirondacks.

Wedderburn was not a prolific writer, committing himself to publication only when he had something of essential significance to impart. This gives an impression of reserve and distinction to his work. The present eminence of American mathematicians in algebra owes not a little to his pioneering, to his excellent teaching and to his editorship-in-chief, for nearly twenty years, of the *Annals of Mathematics*, which in 1911 became the charge of the Department of Mathematics at Princeton, and steadily rose to its present distinguished position among the mathematical periodicals of the world. The volume of the *Annals* published in 1946 was in effect a *Festschrift* dedicated to him. This may be taken as an indication of the respect in which he was held, not only by mathematicians in the United States, but also by mathematicians everywhere. A. C. AITKEN

Dr. George Scott Robertson

GEORGE SCOTT ROBERTSON, permanent secretary of the Ministry of Agriculture, Northern Ireland, died on December 22.

Although his family had been closely associated with Aberdeen for a long period, he was born in 1893 in Middlesbrough, where his father, William Robertson, was for many years editor of the *North Eastern Daily Gazette*. Robertson graduated B.Sc. (Agr.) at Armstrong College, University of Durham, and spent two years there as lecturer in agricultural chemistry. In 1914 he became head of the Chemistry Department of the East Anglian Institute of Agriculture, and in 1920 lecturer in agricultural chemistry at Queen's University, Belfast. A year after going to Northern Ireland he received, for his work on basic slag and rock phosphates, the first D.Sc. degree ever conferred by the University of Durham in its Faculty of Agriculture.

When the Government of Northern Ireland was formed, Robertson's inspiration and drive resulted in the creation of the Faculty of Agriculture in Queen's University, Belfast, which developed in the closest association with the Ministry of Agriculture, Northern Ireland. By 1924 he was professor of agricultural chemistry and dean of the Faculty, as well as senior research officer of the Ministry of Agriculture. By 1933 he became permanent secretary of this Ministry, and for fifteen years directed the work of his Department in peace and war, and saw it grow from a comparatively small organisation into one which to-day touches almost every phase of the life of agricultural Ulster.

Robertson's reputation extended far beyond Northern Ireland. He served with distinction on the Empire Marketing Board, the Imperial Agricultural Bureau, the Food Investigation Board of the Department of Scientific and Industrial Research and the Agricultural Research Council. For many years he was closely identified with the work of Section M (Agriculture) of the British Association; owing to illness, his presidential address at the Brighton meeting last September was read by a colleague.

In 1947 a striking tribute was paid to him when he was invited to become the first director of the new Agricultural Production Division of the Food and Agriculture Organisation of the United Nations. Robertson was absent from Northern Ireland on this work during the greater part of 1947, and when he returned to Belfast it was evident that his health had been impaired by the heavy work he had undertaken—a task superimposed on many years of active endeavour.

Robertson's great services to agriculture in Northern Ireland and in the furtherance of agricultural science throughout the world generally were recognized by Queen's University last year, when the degree of LL.D. (*honoris causa*) was conferred upon him.

His publications include "Basic Slags and Rock Phosphates" (1922) and many other contributions to scientific journals. His main research work was concerned with phosphatic fertilizers in Essex and later in Northern Ireland—investigations which were of outstanding importance and are quoted to-day as classics in their sphere—and pioneer work in collaboration with Sir John Boyd Orr on the mineral requirements of farm livestock.

Robertson was respected for his outstanding ability and qualifications as a leader by his colleagues. He was held in deep and abiding regard as a friend by very many who will mourn his loss.

J. HOUSTON

M. Louis Rapkine

LOUIS RAPKINE was born at Chichenich in White Russia on July 14, 1904. His father, who was a tailor, migrated to Paris in 1911, taking his family with him, and after a difficult year, went to Montreal, where he worked in a factory. Rapkine grew up as a Canadian citizen. He gained his school education by scholarships. He was a good athlete, excelling in netball and swimming. He spent three years at McGill University, supporting himself by working in the summer vacations. When he was twenty, he left Canada to pursue scientific research in France.

Rapkine's scientific training was unusual, for he never took a doctorate. He worked in the laboratories of Caullery and Fauré-Fremiet, and in Wurmser's laboratory at the Institute of Physico-Chemical Biology. In France, at first, he had very meagre means of support. He kept himself by hawking in the countryside and selling boots at country fairs. Sometimes he starved, and was reduced to eating glucose from laboratory bottles.

In spite of these conditions, Rapkine did important work before he was twenty-one. With various collaborators, he published in 1925 extensive observations on the hydrogen ion concentration in egg-cells by the micro-injection of dissolved indicators. He investigated the oxidation-reduction potentials of the nucleus and cytoplasm, and showed that the old idea that the nucleus was a special centre of oxidation was without foundation. His situation was relieved by the award of a Rockefeller fellowship in 1926. He found that the respiratory quotient for the echinoderm egg at four hours after fertilization was extremely high, and then slowed down. He concluded, contrary to Warburg and Shearer, that in the initial period oxidation-reduction was concerned with synthesis, and independent of respiratory processes. He published a monograph in 1928 on the energetics of the development of the egg. He pointed out that the developing organism may have at its disposal sources of energy other than complete combustion to carbon dioxide and water, and remarked that peak-protein catabolism coincides precisely with the stage of development at which chick embryos best provide plasma for tissue culture. In the same year, he was appointed assistant at the Institute of Physico-Chemical Biology, and afterwards received appointments from the Centre National de la Recherche Scientifique.

Rapkine found that the fertilization of sea-urchin eggs was connected with changes in sulphydryl groups. Multiplication of cells depended on their presence. He was thus led to the study of enzymes. He found that the oxidation of sulphydryl groups was much more rapid when the enzymes were separated from their co-enzymes. He supposed that this was because the co-enzyme was attached to the enzyme in the region of sulphydryl groups, disturbing the access of oxidizing molecules.

The late Sir Frederick Gowland Hopkins had arrived at similar results in part of the sulphydryl work. When he heard of Rapkine's work, he withdrew, so that the younger man should be assured of priority.

By 1939, after a hard struggle, Rapkine was scientifically established. He was thirty-five years old, and had arrived at about the same stage as Hopkins at a similar age. There were resemblances between them in unorthodoxy of career and quality of mind. He became a French citizen just before the Second World War. At the outbreak he was mobilized and sent to London to the office of the French coal-importing organisation, where he compiled statistics.

When France was invaded in 1940, Rapkine set himself to save French scientific workers from the enemy. He compiled a list of fifty-seven, whom he endeavoured to rescue. Without any authority other than his own character, he secured the support of the highest scientific and political personalities in London and Washington. He organised the escape of about forty leading scientific workers from France to the United States. He obtained posts for them, and even got their hospital bills paid.

In 1943 Rapkine negotiated an agreement with the British authorities for the establishment of a French Scientific Mission. He brought the group of French scientific workers in the United States to London to be its staff. This enabled France to receive during and after the liberation much new scientific knowledge and experience. As a consequence, a permanent secretary for Franco-British scientific exchanges was attached to the French Embassy in London. In recognition of this work, he was appointed a Chevalier of the Legion of Honour. Rapkine's last act as an administrator was to negotiate a donation of 350,000 dollars from the Rockefeller Foundation for the assistance of research in France.

Rapkine had revealed unique powers of leadership. Nevertheless, he hurried back to personal research. The Pasteur Institute created a Department of Cell Chemistry for him, and he threw himself passionately into its development. He aimed at the solution of the mechanism of enzyme action. He believed that a single enzyme might be capable not only of one specification, but of many. He was organising a co-ordinated attack on this problem.

Rapkine's premature death, on December 13, is a disaster not only to his relatives and friends, but also to science, and to France. He had an extraordinary combination of moral strength, personal charm and intelligence, kindness, generosity and selflessness, besides practical and scientific ability. Many of those who knew him well regarded him as the finest man of his generation. His wife, who assisted him in his scientific work, and his daughter survive him. J. G. Crowther

---

NEWS and VIEWS

Recent Medal Awards: Geological Society of London

The Council of the Geological Society has announced the following awards: Wollaston Medal, to Dr. Robert Broom, in recognition of his researches in the field of vertebrate palæontology, especially in the study of the evolution of the reptiles and of the anthropoid apes and man; Murchison Medal, to Dr. E. M. Anderson, in recognition of his investigations of the igneous, metamorphic and stratigraphical geology of Scotland, and of his many original contributions in the field of geophysics; Lyell Medal, to Dr. W. J. Arkell, for his geological researches, especially on the stratigraphy, structure and palæontology of the Jurassic rocks of Great Britain; Bigsby Medal, to Prof. W. Q. Kennedy, in recognition of his petrological researches and for his outstanding contributions in the field of tectonic geology; Wollaston Fund, to Mr. E. C. Martin, for his work on the Chalk Tertiary and Pleistocene succession in Sussex, and his valuable contribution to geological science as treasurer of the Geologists' Association for thirteen years, including the war years; Murchison Fund, to Dr. S. O. Agrell, for his work on the adinoles of Dinas Head, Cornwall, and his mineralogical observations on some basic open-hearth slags; a moiety of the Lyell Fund, to Dr. W. D. Evans, for his work on the Ordovician rocks of north Pembrokeshire, on air-borne dusts in collieries and on the Midland iron-ore of coalfields; another moiety of the Lyell Fund, to Dr. P. E. Kent, for his geological investigations in East Africa and in the United Kingdom.

Royal Astronomical Society

The Council of the Royal Astronomical Society has made the following awards: Gold Medal to Prof. Sydney Chapman, Sedleian professor of natural philosophy in the University of Oxford, for his contributions to geophysics and solar physics, and particularly to the theory of geomagnetic phenomena; Jackson-Gwilt Medal and Gift to Mr. Algernon Montague Newbegin, for his observations of solar prominences and sunspots during the past forty years.

Institution of Mechanical Engineers

The James Watt International Medal of the Institution of Mechanical Engineers has been awarded to Dr. Fredrik Ljungström, of Sweden, for his outstanding contributions to the development of mechanical engineering, the most notable of which are the air preheater which bears his name and the steam turbine developed jointly with his brother, the late Birger Ljungström. The Medal is awarded every two years to an engineer who has achieved world-wide eminence in some branch of mechanical engineering.

Engineering at University College, London : Prof. G. T. R. Hill

PROF. G. T. R. HILL retired at the beginning of the present academic session from the Kennedy chair of mechanical engineering at University College, University of London, which he had held since 1934. During the First World War, Prof. Hill was engaged in aerodynamic research and acted as observer during flight trials on new and experimental types of aeroplanes. Awarded a commission in the Royal Flying Corps in 1916, he was posted overseas to France, was awarded the Military Cross and promoted to the rank of captain. In 1917 he was posted as a flight commander to an experimental station of the Royal Aircraft Factory. In 1918 he was posted to the Air Ministry as deputy head of the section responsible for dynamics research. After demobilization in 1919, he worked with Messrs. Handley Page as chief test pilot and experimental engineer, until in 1922 he was awarded a senior studentship by the Commissioners of the 1851 Exhibition. Later, with the aid of a grant from the Aeronautical Research Committee, he completed the design of the tail-less aeroplane (Pterodactyl). This work was taken over in 1926 by the Westland Aircraft Works, whose staff he then joined, and thereafter with the aid of experimental contracts by the Air Ministry he developed a type of Pterodactyl for war purposes.

Prof. Hill's work has covered a wide field in applied science, involving problems in ballistics, hydraulics, optics, electricity, as well as metallurgy and mechanical engineering. As a lecturer at engineering societies, schools, Royal Air Force units and other bodies throughout Britain, Prof. Hill is known for the ever delightful lucidity by which he illustrates intricate problems connected with his special subject. In college he was a delightful colleague, always maintaining close interest in matters affecting staff and students, and his outstanding work in the University of London Air Squadron greatly helped to maintain contacts and the thrill of his earlier years. His associates throughout University College will miss his pleasing personality.

Northern Ireland Ministry of Agriculture : Mr. D. A. E. Harkness, C.B.E.

MR. D. A. E. HARKNESS, senior assistant secretary in the Northern Ireland Ministry of Agriculture, has been appointed secretary in succession to the late Dr. G. Scott Robertson. Mr. Harkness was acting secretary in the Ministry when Dr. Robertson was given leave to become the first director of agricultural production and research under the Food and Agriculture Organisation. He graduated in the University of Glasgow and became assistant to the professor of economics at Queen's University, Belfast, before joining the Northern Ireland Ministry of Agriculture in 1924 as chief of the Statistics and Intelligence Branch. In 1926 Mr. Harkness was appointed lecturer in agricultural economics at the Queen's University, a position which he held until shortly after his appointment as assistant secretary in the Ministry in 1936. He became senior assistant secretary in 1939.

Committee on Interrelations of Pleistocene Research

IN June 1947 a new committee, known as the Committee on Interrelations of Pleistocene Research, was set up under the Division of Geology and Geography of the National Research Council, Washington, D.C. This Committee, which stresses the fact that research in this significant field involves numerous disciplines, is under the chairmanship of Dr. Richard F. Flint, professor of geology, Yale University. Its objectives are : (*a*) to study the field of Pleistocene studies and to survey research in progress ; (*b*) to prepare a report on the various lines of research now being carried out ; and (*c*) to suggest problems that should be attacked, with special emphasis on those involving two or more disciplines. The list of members and the fields covered by each provide an indication of the effort being made by this group to achieve broad representation. The members are : Dr. Edward S. Deevey, jun., lecturer in biology, Yale University (biogeography) ; Dr. Loren C. Eiseley, professor of anthropology, University of Pennsylvania (anthropology and New World archæology) ; Dr. Claude W. Hibbard, associate curator of vertebrates, Museum of Palæontology, University of Michigan (vertebrate palæontology) ; Prof. Chauncey D. Holmes, professor of geology, University of Missouri (glacial erosion and sedimentation) ; Dr. Helmut E. Lansberg, deputy director, Committee on Geophysical Sciences, Joint Research and Development Board, Washington, D.C. (meteorology and climatology) ; Dr. Hallam L. Movius, jun., curator of palæolithic archæology, Peabody Museum, Harvard University (Old World archæology) ; Dr. Fred B. Phleger, jun., asst. prof. of geology, Amherst College (oceanography and sea-floor geology) ; Dr. Louis L. Ray, United States Geological Survey (glacial stratigraphy and alpine glacial geology) ; Dr. H. T. U. Smith, associate professor of geology, University of Kansas (eolian features, frozen ground and stream terraces) ; Dr. James Thorp, principal soil scientist, United States Dept. of Agriculture (soil science). This group is especially anxious to correspond and exchange reprints with foreign workers interested in various aspects of the Pleistocene, and to obtain information concerning research now in progress.

On April 5 and 6, 1948, the Committee held its first meeting, at which were discussed several measures looking towards closer co-operation among those working in the various fields that deal with the Pleistocene. It was decided to publish a series of articles in 1949 covering some of the major problems, which may be assembled in a single volume for distribution by the Division of Geology and Geography of the National Research Council. Plans were made to compile a map showing the distribution of the loess and wind-blown deposits of North America. It is felt that the ground-work has been laid for breaking down certain of the arbitrary divisions between the various disciplines, the existence of which has so badly hampered Pleistocene research up to the present (see also p. 186 of this issue).

International Book Token Scheme

A SCHEME has been devised by Unesco to overcome foreign-exchange difficulties and so enable educational and scientific institutions in 'soft' currency countries to buy publications from 'hard' currency countries. Purchases will be made in the national currency of the countries concerned, and Unesco will supply the necessary dollars. The plan will operate for an experimental period of one year and is limited to 150,000 dollars worth of book coupons, which will be shared by eleven countries, including Great Britain. If it is successful, however, the scheme may be expanded to include all member

States of Unesco. The coupons may be used to buy books on education, science and culture, the importation of which is prohibited by importing laws. They can also be used for subscriptions to periodicals, for the purchase of individual volumes or issues and for the payment of photo copies. The coupons will be available in denominations ranging from 25 cents to 10 dollars. Other countries where the coupons will be on sale are: China, Czechoslovakia, France, India and Poland. In addition, a limited free distribution, financed by Unesco, will be made in Austria, China, Czechoslovakia, Greece, Hungary, Italy, the Philippines and Poland. The coupons of each participating country will be handled by its own national distributing body, and in Great Britain this function is being undertaken by Book Tokens, Ltd., 28/30 Little Russell Street, London, W.C.1, from whom all particulars may be obtained. It is pointed out that as the amount of dollars available is limited, coupons will be allocated on a priority basis, and the needs of educational, scientific and cultural institutions serving a large public will be given first consideration.

Northern Advisory Council for Further Education

In March and April of 1947, the Minister of Education issued directions to local education authorities to prepare and submit schemes for further education and plans for county colleges. In Circular 133, containing directions for further education, the Minister reminded local education authorities that they are required when preparing their schemes to "have regard to facilities provided by other bodies and to consult such bodies and local education authorities for adjacent areas". The procedure for the consultations referred to in Circular 133 was discussed by the Northern Advisory Council for Further Education at its meeting in October 1947, when it was decided that the first step should be the preparation of an agreed draft by a committee consisting of the 'chief education officers' of the constituent authorities. Its report has now been prepared and was approved by the Council in November 1948. Adult education, county colleges, community centres and other kinds of further education were considered to lie outside the scope of the Committee, and its deliberations were confined to technical, commercial and art education as provided in the main colleges. Starting from the broad principle that each authority should be free to provide for its own residents up to the national certificate stage, provided that numbers justified this measure, the Committee has worked out a detailed programme in which technical education in the north-east area could function as an integrated regional scheme. Implementation of the recommendations in this report would do much to provide Great Britain with adequate numbers of the technically trained persons who are so urgently required. Copies of the report may be obtained from 43 Eldon Place, Barras Bridge, Newcastle-upon-Tyne, 1.

Magnetic Field of the Sun

A recent paper by Prof. S. Chapman (*Mon. Not. Roy. Astro. Soc.*, 108, No. 3; 1948), with the title "Solar Magnetism and the Suggested Fundamental Magnetization by Rotation", deals with the difficulties in accepting the 'fundamental' hypothesis, recently revised by Blackett. According to this hypothesis, the general magnetic fields of the earth, the sun and of certain stars introduce a new fundamental property of rotating bodies which can be expressed by the formula $P/W = \beta G^{1/2}/2c$, P being the axial component of the dipole magnetic moment, W the angular momentum, G the constant of gravitation, c the speed of light, and β a factor of the order unity (for the earth it is 0·3). It was pointed out by Bullard that the fundamental hypothesis seems to imply a downward decrease of intensity of the geomagnetic field within the earth, and measurements since made in South Africa and in England provisionally support the hypothesis (see *Nature*, **160**, 746; 1947; **161**, 462; 1948). Chapman develops the consequences of the hypothesis—in particular as to the nature of the internal fields of the earth and sun—basing his calculation on the density distribution given by Blanch, Lowan, Marshak and Bethe for the point convective model of the sun, and taking into account a non-uniform distribution of the angular velocity approximating to that given by Schwarzschild. The corresponding moment of inertia and angular momentum of the sun are calculated, and β is estimated to be 2 if the sun's polar magnetic intensity is 50 gauss; but accepting Thiessen's recent value of 10 gauss, or less, β cannot exceed 0·4, which is close to 0·3, the value of β for the earth. The inferred intensity at the centre is a few thousand gauss, similar to that of sunspot magnetic fields. The fundamental theory seems incapable of explaining the existence of the intense sunspot magnetic field, and this weakens the case for postulating a new fundamental property of matter to explain the general magnetic field. It is admitted, however, that it is remarkable, and may be profoundly significant, that the ratios of the values of P, extending over a considerable range, for the earth, the sun, and certain stars, to the associated values of W, differ by less than one factor of ten.

Suggestions for Science Teachers in Devastated Countries

Unesco has recently published an illustrated booklet showing how teachers lacking elementary scientific equipment can make apparatus from simple everyday materials. The booklet has been prepared by Mr. J. P. Stephenson, science master at the City of London School, who first explains how science teaching can be commenced without the use of apparatus and then shows how equipment for experiments in astronomy, meteorology, heat, light, magnetism, electricity, chemistry and biology can be improvised from materials such as wood, glass-tube, wire, nails, bottles and other household articles.

A note is also included on the use of visual aids in science teaching together with a description of recent laboratory materials, such as plastics and alloys, and a section on laboratory receipts, charts and logarithm tables. The booklet is being distributed free by Unesco to schools in Greece, Poland, Czechoslovakia, Austria, Hungary, Italy, China and the Philippines, with the hope that it may lead to further improvisation in apparatus for elementary science teaching. It should be interesting later to see what influence this booklet has on the teaching of science in the recipient countries.

Paper Supplies for Books

In a written reply to a question in the House of Commons, the President of the Board of Trade states that from March 6 the licensing arrangements for paper will be considerably simplified. As a result, paper for books, stationery, boxes, cartons and many minor uses should be freely available without individual licences or quotas up to the full extent of the limits set by the supply position. Bulk licences will be given to paper makers and importers authorizing them to deliver or convert any paper produced or imported by them, with certain specific exceptions, which include newsprint, insulating cable paper, certain classes of paper used for packaging, etc. The use of paper for newspapers and periodicals will still be restricted by the provisions of the Paper Control Orders. The improvement in the supply position from non-dollar sources, it is stated, has made these modifications possible, and the need to maintain waste paper salvage at the highest possible level remains as great as ever.

Symposium on Animal Speciation

A symposium on "Ecological and Genetic Factors of Speciation in Animals" was held by the Istituto Italiano di Idrobiologia, Pallanza (Novara), Italy, during July 29–August 2. The meeting was sponsored by the Consiglio Nazionale delle Ricerche (Italian National Research Council), whose general secretary, Dr. A. Morelli, opened the symposium, which was attended by thirty-four biologists. Papers were read by: E. Baldi, Pallanza (isolation mechanisms in populations of plankton freshwater crustaceans); M. Benazzi, Pisa (genetic-systematic studies on Triclades); F. G. Brieger, Piracicaba (heterosis in population-genetics and evolution); H. Burla, Zurich (ecology of *Drosophila* species of Switzerland); U. D'Ancona, Padua (Nemi's Daphniæ during twenty-five years of observations); A. Dreyfus, São Paulo (sex-ratio in hybrids and its interpretation by the study of salivary chromosomes); M. Galgano, Florence (ecological and genetic factors in the sexual cycle of amphibians); J. B. S. Haldane, London (importance of disease in evolution and speciation); J. Heuts, Louvain (ecological and genetic factors in the speciation of the fish *Gasterosteus aculeatus*); F. Mainx, Vienna (chromosomal races of the Agromyzine *Lirryomiza*); B. Rensch, Münster (histological transformations by change in body size); H. Spurway-Haldane, London (comments on Vavilov's law of homologous variation); V. Tonolli, Pallanza (isolation and stability of high-mountain Diaptomid populations); L. Trevisan, Pisa (evolution of the elephants during the Quaternary). Prof. Th. Dobzhansky, of Columbia University, New York, introduced the theme for discussion, and at the end of the meeting summed up the proceedings. The papers will be published in a special volume, edited by the Consiglio Nazionale delle Ricerche.

The Night Sky in February

Full moon occurs on Feb. 13d. 09h. 08m., U.T., and new moon on Feb. 27d. 20h. 55m. The following conjunctions with the moon take place: Feb. 13d. 22h., Saturn 3° S.; Feb. 23d. 23h., Jupiter 5° N.; Feb. 25d. 07h., Mercury 6° N.; Feb. 26d. 15h., Venus 4° N. In addition to these conjunctions with the moon, Mercury is in conjunction with Venus on Feb. 10d. 08h., Mercury 4° N. Mercury sets less than half an hour after the sun on Feb. 1 and is in inferior conjunction on Feb. 2. At the middle of the month the planet is stationary and rises an hour before sunrise, but it is not favourably placed for observation during February. Venus is a morning star, rising at 6h. 56m., on Feb. 1 and 14, and at 6h. 40m. towards the end of the month, but is then too close to the sun for observation. Mars is still too close to the sun for favourable observation. Jupiter rises at 6h. 35m., 5h. 55m. and 5h. 08m. on Feb. 1, 14 and 28, respectively, and can be seen, but not favourably, for a short time in the eastern sky. Saturn is in opposition to the sun on Feb. 21 and is visible in the constellation of Leo Major, a little east of Regulus, during the night. Occultations of stars brighter than magnitude 6 are as follow: Feb. 3d. 21h. 13·4m., *e* Pisc. (*D*); Feb. 4d. 20h. 43·4m., 54 Ceti (*D*); Feb. 15d. 22h. 47·1m., η Virg. (*D*); Feb. 15d. 23h. 34·3m., η Virg. (*R*). *D* and *R* refer to disappearance and re-appearance, respectively, and the latitude of Greenwich is assumed.

Announcements

The Committee of Privy Council for Agricultural Research has appointed Prof. F. T. Brooks, who has recently retired from the chair of botany in the University of Cambridge, to be a member of the Agricultural Research Council. This is Prof. Brooks' second term of office as a member, his first being during 1941–46.

The Swiney Prize for 1949 has been awarded, on the recommendation of a joint committee of the Royal Society of Arts and the Royal College of Physicians, to Prof. John Glaister, of the University of Glasgow, for his work "Medical Jurisprudence and Toxicology". This is the second occasion on which Prof. Glaister has received the Swiney Prize, it having been awarded jointly to him and Prof. J. C. Brash in 1939 for their book "Medico-Legal Aspects of the Ruxton Case". The Prize, which is offered alternately for medical and general jurisprudence and consists of a £100 silver cup and money to the same amount, is awarded on every fifth anniversary of Dr. George Swiney's death on January 21, 1844.

Mr. A. L. Bacharach has been appointed to the staff of the Public Relations Director, Glaxo Laboratories, Ltd.; his long scientific and editorial experience will thus be available to assist all sections of the Company's public relations organisation. Dr. W. F. J. Cuthbertson will succeed him as head of the Nutrition Unit, Research Division, of Glaxo Laboratories, Ltd.

The date for the receipt of applications for the Nuffield Foundation Research Fellowship in Extraction Metallurgy has been put forward to March 31, 1949. The Fellowship will be tenable at the Royal School of Mines, London, for a period of up to five years, and the funds available are sufficient to provide a salary of £1,200–£1,500 a year, as well as some £2,500 a year for assistants and apparatus. Applications should be sent to the Secretary, Institution of Mining and Metallurgy, Salisbury House, London, E.C.2.

Referring to the communication "Occurrence of *Acanthocephalus ranæ* Schrank. in Great Britain" (*Nature*, 162, 1001; 1948), Dr. N. B. Eales, of the University of Reading, writes: "Mr. R. Phillips Dales has recorded the occurrence of *Acanthocephalus ranæ* from the duodenum of frogs from either Cornwall or Surrey. We have also obtained this parasite from frogs caught locally during 1948. It is therefore not improbable that the specimens at Queen Mary College came from the frogs in the neighbourhood of London."

Erratum. In the communication "Relationship Between the Average Carcase Weight of Rams, Ewes and Lambs" (*Nature*, January 15, p. 100), for "$R + E = \Pi L$", read "$R + E = \pi L$".

Disintegration of Boron-10 by Protons

The Atomic Energy Research Establishment, Harwell, has recently produced a number of separated stable isotopes in milligram quantities. The availability of such isotopes has already enabled new nuclear reactions to be discovered, and old ones to be confirmed. In this and a later communication we wish to report on some work of this nature with boron and magnesium.

In the work with boron we have observed the α-particles expected in the reaction[1]

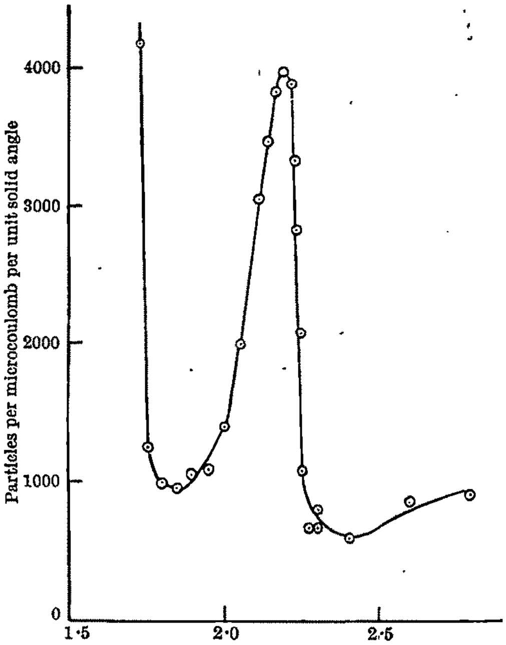
$$B^{10} + H^1 \rightarrow Be^7 + He^4 \tag{1}$$

by using the magnetic analyser and photo-electric multiplier described in a previous communication[2]. Short-range α-particles from the disintegration of boron-11 were eliminated by using a target of separated boron-10. The accompanying graph shows the number of particles counted as a function of current through the analyser coils, for a proton energy of 530 kV.; the α-particle group from reaction (1) is clearly resolved from the scattered protons. The yield of α-particles was found to increase smoothly as the proton energy was varied between 400 and 800 kV.

The energy of the α-particles was measured by putting an absorption cell with a 2-mm. mica window between the analyser and the fluorescent screen, and finding the pressure in the cell at which the particles were cut off. This was compared directly with the cut-off pressure for the α-particles from the reaction[3]

$$Be^9 + H^1 \rightarrow Li^6 + He^4, \tag{2}$$

for which the Q-value was taken to be 2·074 MeV. The difference in extrapolated range of the α-particles from reaction (1) at 630 keV. proton energy, and from reaction (2) at 860 keV., was found to be 0·35 ± 0·01 cm. of air; if the difference in straggling of the two groups is neglected, this gives a mean range of 0·56 ± 0·01 cm. for the α-particles from reaction (1). The corresponding energy release is 1·04 ± 0·06 MeV., using the Cornell range velocity curve[4]. This is to be compared with the value of 1·15 MeV. predicted from the masses[5].



Disintegration of boron-10 by 530-kV. protons; magnetic analysis of particles from the target

As a check on this energy release the magnet current at which the α-particles from reaction (1) were observed was accurately determined. By comparing this with the current necessary for the observation of other known α-particle groups, including that from reaction (2), an energy release of 1·05 ± 0·07 MeV. in reaction (1) was obtained, in good agreement with the result from the range measurement.

It is possible that the beryllium-7 nucleus is formed in an excited state in reaction (1), but we have been unable to find any evidence of α-particles corresponding to transitions to the ground-state in numbers exceeding 10 per cent of the main group at the particular angle of observation (83° with the incident protons).

We wish to thank Sir John Cockcroft and Dr. W. D. Allen and members of his group at the Atomic Energy Research Establishment, Harwell, who supplied the boron-10 target used. One of us (J. M. F.) is indebted to the Australian Council for Scientific and Industrial Research for a studentship.

Specific Ionization of Fast β-Particles in a Mixture of Air and Ethyl Alcohol – Water Vapour

Curran and Reid have given an account[1] of their investigations on the primary ionization of β-particles in mixtures of argon and ethyl alcohol vapour. I have carried out some experiments on the specific ionization of fast β-particles in a mixture of air and ethyl alcohol – water vapour[2].

A detailed study was made of the influence on the ionization in air of the mixture of ethyl alcohol and water generally used as a source of vapour in the Wilson cloud chamber. To this end both the probable and the primary ionization in air were determined at three pressures, namely, at 1, ½ and ¼ atmosphere. Assuming the specific ionization in pure air in this region to increase linearly with the pressure, it is possible to deduce from the observed values the specific ionization in the vapour-mixture.

The experiments were made for β-particles of various energies, namely, with a ρH of 1,200, 1,600, 2,000 and 2,400 gauss/cm. The mean specific ionization in ethyl alcohol – water vapour (liquid 60/40 by volume) at 0° C. and 1 cm. mercury pressure, at the energies stated, was 3·86, 3·24, 2·71, 2·45 ion pairs/cm. for the probable ionization and 2·22, 1·68, 1·35, 1·18 ion pairs/cm. for the primary ionization respectively.

It follows from these figures that the mean specific primary ionization for a β-particle of energy 0·4 MeV.

in an ethyl alcohol – water vapour mixture at 0° C. and 76 cm. mercury pressure amounts to about 90 ion pairs/cm., a number which is somewhat higher than the value of 79 ion pairs/cm. for alcohol vapour found by Curran and Reid and determined by the method of placing two counters in a spectrograph.

Directional Correlation between Successive Internal-Conversion Electrons from Tantalum-181*

HAFNIUM-181 decays with a 48 day half-life to a 20-microsecond metastable state[1] of tantalum-181. From this, two γ-rays are emitted in cascade, with internal conversion coefficients $N_e/(N_e + N_\gamma)$ approximately 0·6 and 0·06 [2]. We wish to report some measurements on the directional-correlation between these successive conversion electrons.

2 mgm. of finely divided hafnia, irradiated with slow neutrons in the Harwell pile to give hafnium-181, was used as a source. Self-absorption in the source of the softer conversion electrons was appreciable. Four Geiger–Müller counters with 2·3-mgm./cm.^{2} windows were placed around the source, each 6 cm. away from it. They were arranged as two pairs to measure the instantaneous coincidence-rates C for two angles at the same time. Angles of 90° and 180° have been used, with an angular resolution of ± 8°. Each counter fed very short pulses (0·3 microsecond) into its coincidence unit, so that delayed coincidences were practically eliminated and the correction for random coincidences was small. The anisotropy was found to be

$$\frac{C\,(180^\circ) - C\,(90^\circ)}{C\,(90^\circ)} = -\,0{\cdot}32 \pm 0{\cdot}08.$$

Check experiments on secondary electrons from unconverted γ-rays showed that effects from these were small.

Extensions of such experiments are being considered, as well as the theoretical implications regarding the multipolarity of the transitions involved and spins of the corresponding nuclear states.

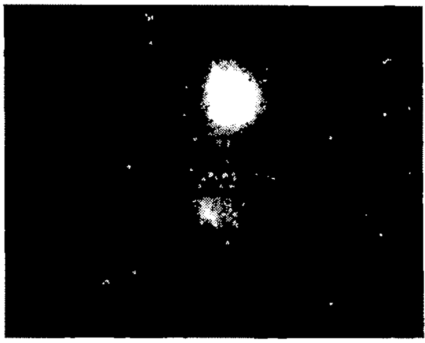
A New Phenomenon in the High-Pressure Mercury Vapour Discharge

THE mechanism of the positive column of the high-pressure mercury vapour discharge appears to be now well understood[1]. It has been a basic assumption in all the theoretical work—and this has been borne out by general experience of the behaviour of the discharge—that the positive column is substantially uniform in all properties along the whole of the distance between the electrodes, at least to within less than a millimetre from the discharge terminations. It is true that there are some exceptions: the column often tends to contract near the electrodes, and in long vertical burning tubes this effect is more marked at the lower end. This contraction is not difficult to understand, and its accentuation at the lower electrode is due to the higher density there compared with that at the upper end of the tube. It is true also that very close to the cathode small intense bright spots may often be seen[2], but it has always seemed likely that this was associated with a purely surface effect on the electrode; and there has been no evidence to suggest that in the high-pressure condition any appreciable degree of axial non-uniformity could be produced.

For some time we have been making observations on discharges in mercury vapour at pressures of the order of 5 atmospheres, and with arc-lengths of the order of 10–20 mm., which are somewhat surprising in view of this long-accepted background.



Bright region in the neighbourhood of the cathode of a high-pressure mercury-vapour discharge showing intense barium spectrum

If a small amount of a relatively easily ionized vapour, such as sodium or barium, is evaporated into the positive column of such a discharge, at high loadings (of the order of 1 kW. per cm. of arc), a large intense region may be produced extending from the cathode over a substantial part of the distance between the electrodes. The accompanying photograph—which was taken through a Wratten 25 filter with a *P*1200 plate—shows the bright region produced in the neighbourhood of the cathode of a D.C. discharge, by the addition of a small quantity of barium vapour to the high-pressure mercury vapour. This bright area has fairly clearly defined edges and radiates an intense Ba spectrum with—less strongly—that of Ba$^+$. Its luminance is some 40,000 Sb., which is about twice that of the remainder of the arc. The phenomenon in its present form seems to be mainly associated with the cathode function, since it appears at this electrode whatever the position of burning of the arc.

Another property which the photograph incidentally shows is that the intense region can be preferentially deflected in a magnetic field.

There are indications that similar phenomena occur in the rare gases at high pressures.

The fact that quite small quantities of an easily ionizable substance are able profoundly to affect the properties of the positive column is not very unexpected; but that a cathode phenomenon of this magnitude can be so produced is of considerable theoretical interest and warrants further study. It is hoped shortly to publish this work in detail.

Radial Patterson Distribution Functions

IT has been indicated in a previous paper[1] how a comparison between the structure factors ($F(h,k,l)$) resulting from a given molecular configuration, and those actually observed by experiment, can be effected by comparing the Patterson maps resulting from the observations and from the proposed molecule. This suffers the disadvantage of requiring a knowledge, not only of the intra-molecular configurations, but also of the positional relationships between the molecules themselves in the unit cell. Another approach is suggested by a result obtained recently[2]. Since the Patterson synthesis, in a certain neighbourhood of the origin, depends mainly upon the intramolecular configuration, a possible basis of comparison between a postulated molecular structure and a set of observations would lie in an investigation of the distribution functions resulting from each in *Patterson* space.

It is simple to obtain the radial Patterson function of a given molecule by the processes of elementary geometry. We now investigate very briefly the technique for deriving the same function from the observed $|(F(h,k,l)|^2$ values.

For a radially symmetric function $T(R)$, the corresponding radially symmetric function in the reciprocal space is

$$g(r) = 4\pi w \int_0^\infty R^2 T(R) \left[(\sin 2\pi.rR)/(2\pi.rR)\right] dR,$$

where w is the total weight of $g(r)$ and T is scaled to value unity at the origin. For a cylindrically symmetric function $T(RZ)$, the corresponding function in the reciprocal space is[2]

$$g(rz) = 2\pi w \int_{-\infty}^{\infty} \int_0^\infty RT(RZ)\, J_0(2\pi rR) \exp(-2\pi izZ)\,.\, dRdZ.$$

Hence the three-dimensional radial Patterson function for a unit cell of volume V may be written

$$g_3(r) \doteqdot (1/V) \sum_3 |F(h,k,l)|^2 \sin(2\pi rR_{h,k,l})/(2\pi rR),$$

where $1/R_{h,k,l}$ is the spacing of the plane (h,k,l). The two-dimensional radial Patterson function for a unit cell of volume V may correspondingly be written

$$g_2(r) = (1/A) \sum_2 |F(h,k,o)|^2\, J_0(2\pi rR_{h,k,o}).$$

Applications of the above methods to crystalline powders have been pointed out elsewhere[3], but we wish to remark here their special suitability to work in proteins. In this field a number of theories have been advanced for the structure of single molecules, and any check has been rendered difficult since it requires, not only a knowledge of the single molecule, but also of the relationship which this bears to its fellows in the unit cell. The present technique may permit a first comparison to be made without any consideration of intermolecular structure and with only limited computations. This is important since it will enable certain structures to be ruled out immediately. We wish to emphasize, however, that it can never establish the correctness of a given structure, but only its right to inclusion in the general class of possibilities.

A Mechanical Calculating Machine for X-Ray Structure Factors

A LARGE mechanical machine for calculation of X-ray crystallographic structure factors has now been completed in our laboratories and is running satisfactorily. The machine is of a tide-predictor type, and it deals with up to 24 harmonic components at a time.

The expression calculated is

$$F\,(hkl) = \sum_i f_i \cos 2\pi\,(h\,x_i + k\,y_i + l\,z_i).$$

During the calculation, for example, h and k are kept constant and the machine calculates F for all required l values at one setting. If there are N atoms per unit cell, N harmonic units are switched on; each unit has a phase dial on which is first set the value $h\,x_i + k\,y_i$. The values z_i are set on a multiplier bar, which at each stroke adds these through a clutch to the values on the dials with an accuracy better than 1 : 1,000. After l strokes, the dials thus read $h\,x_i + k\,y_i + l\,z_i$. Their angles are transferred to cosine arms, each of length f_i, the results of which are added together by means of a pulley belt differential with an accuracy better than 0·2 per cent of $F(000)$. An output pulley indicates on two geared-down dials the resulting values of F. The calculation assumes that the variation of f_i with index is the same for all the atoms; heavy atoms must thus be treated separately.

The machine has provision for calculation of Booth corrections[1] ε from the derivatives of R. For this purpose the errors $F_0 - F_c$ are copied from a drum and thus fed into the machine. The machine is run again, but with $\pi/2$ added to the angles of the phase dials of the harmonic units, so that their arms produce sines instead of cosines. There is an arrangement which multiplies these by $W\,(F_0 - F_c)$. The weights W are chosen according to the formula for R used[2], and according to whether x, y or z co-ordinates are to be corrected. The products are summed up on the ε dials for all l. After completing the run, the ε dials read the corrections by which the co-ordinates should be altered to decrease R. The cycle of calculations is represented in Fig. 1.

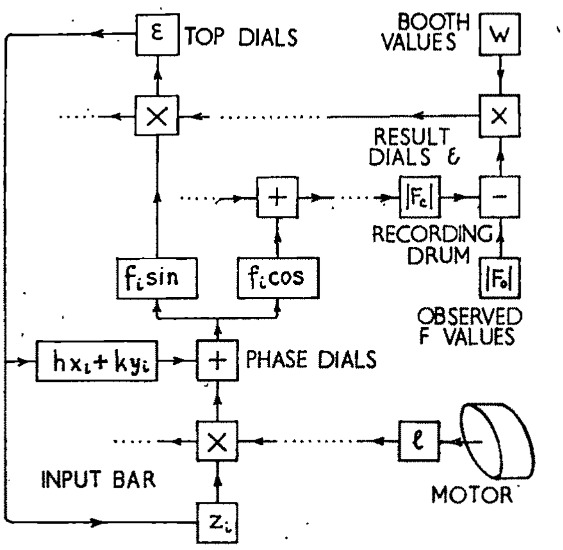

Fig. 1. Calculation cycle of the machine, using Booth's method of steepest descents

The machine is electrically driven, and the drive is automatically controlled, stopping after completion of a predetermined sequence of operations. Taking into account the setting times, it is about thirty times faster than manual methods. The output is of sufficient power to drive a registering pen mechanism. If desired, absolute values can be plotted automatically, each coded by means of a small kink in the curve; positive values have the kink upwards, negative downwards. A plot of *F* values is shown in Fig. 2.

Although this machine was designed for calculation of structure factors, it can be used for Fourier synthesis of the electron density. As the lengths of the cosine arms are not readily adjustable, it is best to set all their lengths equal. The structure factors can then be represented as a sum of two vectors of unit length, differing in phase. The machine is run separately for each set of unit vectors and the results added. A unidimensional continuous electron density tracing is then obtained.

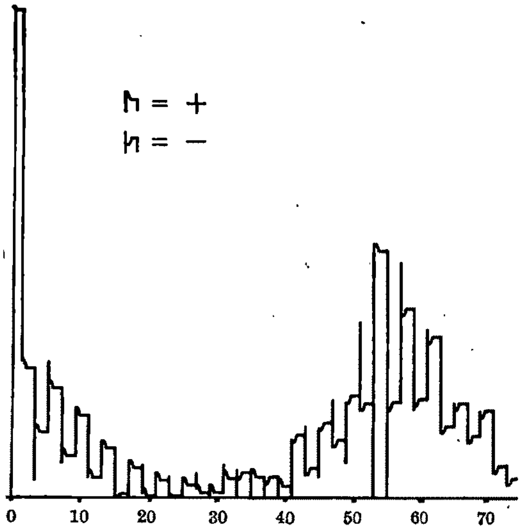

Fig. 2. Automatic recording of *F*(00*l*) values of strontium laurate for *l* up to 74 (odd values of *l* absent). Scale: *F*(000) = 1040 electrons

'Ecofix' girders and 'Meccano' were used for parts where high accuracy was not required; this reduced the cost of the machine considerably and enabled us to build it in less than six months.

I wish to thank Mr. E. T. Sanders for machining the more accurate components.

Quadrupole Rotation-Vibration Spectrum of the Hydrogen Molecule

It is usually considered that molecular hydrogen does not have an infra-red rotation-vibration spectrum. However, such a spectrum may be expected as a forbidden transition made possible by the change of quadrupole moment during the vibration[1]. The predicted intensity of this spectrum is so low that a path of the order of 10 km. at atmospheric pressure is required to obtain it in absorption[1,2].

Using a pipe of 22 m. length and letting the light pass through it up to 250 times[3] at a pressure of 10 atmospheres, it was possible to obtain equivalent path-lengths up to 55 km. atmospheres. Under these conditions a number of lines of the 2–0 and 3–0 bands of the hydrogen quadrupole spectrum were indeed observed. The accompanying table compares the observed wave numbers with those predicted from the ultra-violet hydrogen spectrum[1]. The bands have only *S*, *Q* and *O* branches. Because of the small moment of inertia of the hydrogen molecule, only the first few lines of the *S* and *Q* branches are sufficiently intense for observation. No lines of the *O* branches were found.

Wave-numbers of quadrupole lines of H_2

Band	Line	ν (predicted)	ν (observed)
2–0	*S*(0)	8,403	8,406·36
2–0	*S*(1)	8,601	8,604·26
2–0	*S*(2)	8,782	8,785·54
2–0	*Q*(1)	8,072	8,075·42
3–0	*S*(0)	12,080	12,084·66
3–0	*S*(1)	12,261	12,265·55
3–0	*S*(2)	12,420	12,424·44
3–0	*Q*(1)	11,760	11,764·96

The slight systematic difference of observed and predicted wave-numbers is due to the much lower wave-number accuracy in the vacuum ultra-violet and the lack of standards in this region. It is hoped to obtain improved rotational and vibrational constants of the hydrogen molecule in the ground-state from the wave-numbers of the quadrupole lines.

It appears that the spectrum here observed is the first example of quadrupole radiation in molecular spectra.

Radiation Pressure of Centimetre Waves

THE pressure exerted on a perfectly specular surface by a normally incident beam of electromagnetic waves travelling in free space can be calculated with the known formula

$$p = 2S/c,$$

where S is the Poynting vector and c the speed of light.

Many experiments have been performed in order to measure the pressure exerted by light waves, among which those by Amerio[1] seem to be particularly elegant. Lebedew[2] has found for the radiation emanating from the sun a pressure of the order of 10^{-5} dyne/cm.^{2}. The radiation pressure of electromagnetic waves produced by ordinary radio transmitters is smaller still and cannot be detected by direct means, since the wave-lengths involved are too large and the power does not reach adequate levels. The invention of new tubes (magnetrons) capable of generating high-power centimetre waves has made it possible to measure the radiation pressure of such radiation.

Using a 725 A.-type magnetron generating bursts of radio-frequency energy ($\lambda = 3$ cm., duration of each burst 1 μsec. with a recurrence of 1,000 cycles per second) of a mean value of 50 watts, the pressure exerted by the energy impinging on a surface of 2 cm.^{2} (cross-section of rectangular wave-guide) is of the order of 10^{-2} dyne/cm.^{2}.

In order to detect such a pressure we have carried out the following experiments: before the mouth of a rectangular wave-guide excited by the above-mentioned magnetron, we placed the aluminium blade (6 cm.^{2} cross-section) of a symmetrical torsion balance, having an arm 2 cm. long, protected by a glass cover. Observation was carried out in a rarefied atmosphere of 10 mm. mercury pressure approximately in order to minimize radiometer effects. The distance between the blade and the mouth of the wave-guide was never less than 4 cm. in order to avoid ionization under the action of the intense radio-frequency field.

Thus the blade was picking up only a fraction of the radiated energy. Different observations have been made at various points of the field. When intercepting the maximum radiation (approximately one fifth of the total available power), the balance indicates a torque of 10^{-2} dyne/cm. Diffraction phenomena explain this result, which is smaller than the theoretical torque corresponding to a force obtained by calculating the product of the pressure of the intercepted radiation by the effective cross-section of the blade.

In a theoretical paper[3], in which the propagation of the electromagnetic field in a wave-guide has been studied starting from relativistic considerations, we have demonstrated that within a (rectangular) wave-guide the pressure must be calculated with the formula:

$$p_g = 2Sv_g/c^2,$$

where v_g is the group velocity, which is known to be less than c. We deduce from it a radiation pressure within the wave-guide less than the free space radiation pressure.

Measurements of p_g are under way, and since v_g is a calculable quantity, we hope to be able to obtain as final result the value of S and consequently the generated power.

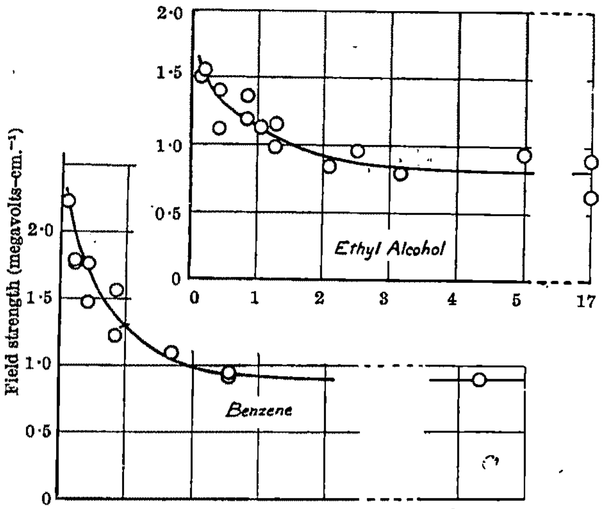
Dielectric Strength of Liquids for Short Pulses of Voltage

EXPERIMENTS in progress here show a systematic increase in the dielectric strength of pure organic liquids as the duration of the pulse of voltage is decreased. In other words, between the instant of applying a field and the instant of breakdown there is a time-delay which becomes less as the field-strength is raised above the normal breakdown value. A suggestion of this delay can be seen in the early oscillograms of Rogowski, Flegler and Tamm[1].

We have used pure organic liquids of relatively simple molecular structure, both polar and non-polar. The accompanying graph shows the experimental relation between breakdown field-strength and pulse duration for benzene and alcohol. The experiments were performed at room temperature.



Dependence of dielectric strength upon pulse duration for benzene and alcohol

To avoid the considerable errors due to minute amounts of impurity, an apparatus has been constructed in which the liquid can be distilled *in vacuo* into the testing vessel. Single rectangular pulses of voltage are applied from a thermionic pulse generator to a pair of polished metal spheres immersed in the liquid and capable of being rotated from outside the vessel to present a fresh surface to the gap after a spark has occurred. We find that this apparatus reduces the 'spread' in the measurements, though a small proportion of the pulses still produce breakdown at field-strengths below the minimum value for consistent rupture, which we regard as the 'breakdown field-strength'. However, accidental lack of ionization does not seem to play a major part in delaying breakdown, as in gases.

A high-speed single-stroke cathode ray oscillograph is used to observe and measure the pulses. We agree with Rogowski and his collaborators that the breakdown, when once started, becomes complete in about 10^{-9} sec.

A recent theory[2] of breakdown in amorphous dielectrics indicates that, above a certain critical field-strength, instability of the energy of the electrons in the conduction band occurs. It does not, however, go into the question of the time required to reach the state of instability from the moment of applying the field, neither does it deal with the events following the establishment of the unstable state. It is hoped that further experiments will show whether the time-delay we have found is associated with one or both of these possible causes.

Frictional Electrification

Recent experiments on the so-called frictional electrification produced when dielectrics slide over conductors appear to throw light on the mechanism of its production.

Small cubes of ebonite or a measured volume of sand were allowed to slide down an earth-connected inclined metal plane and fall into a tin connected to an electrometer triode valve. The bodies were carefully discharged before starting, and the reading of the valve instruments gave a measure of the charge acquired in the slide. Above and parallel to the runway was another plate insulated from it, and by putting a potential between the two plates the specimens could slide in an electric field perpendicular to the sliding surface—there was an air gap of a centimetre or so between the top of the specimen and the upper plate.

It was found that this electric field had a considerable effect on the frictional charges produced, and that there was the simple relation

$$Q = -AX - Q_0$$

for any particular specimen, where Q was the frictional charge for an electric force of X volts per cm., $-Q_0$ was the frictional charge when sliding in zero field and A was a constant (X was taken as positive when the upper plate was at a positive potential to the lower).

Thus with ebonite or sand in zero field, a negative charge was produced; making the top plate positive increased the magnitude of this charge, while making it negative decreased it, and if sufficiently negative reversed its sign. In each case for a negative field, given by the value Q_0/A for the substance, no charge was produced by the slide. This effect of an electric field gives a clue to the mechanism of frictional electricity.

The only way in which the dielectrics can acquire the charge is by the passage of electrons to or from the plate down which they slide. There is, thus, although the dielectrics are insulators, a leakage of charge over the contact surface, which continues until the external field is neutralized. If this were all, the curve connecting Q and X would be a straight line through the origin. The fact that it is a straight line but not through the origin proves that another field must also be present, due to a type of contact difference of potential between the dielectric and the plate. When there is no field, the passage of charge to neutralize this contact potential gives rise to the charges known as frictional electricity.

The effect of an external electric field, besides its theoretical interest, may have a practical use; because by the application of the appropriate field Q_0/A (usually a moderate one of a few hundreds of volts per cm.) it is possible to prevent sliding particles getting any charge at all and thus get rid of certain dangers due to frictional electricity.

It would, however, be over-optimistic to expect a complete cure, because the phenomenon being a surface one, the magnitude of Q_0 and A, and therefore of Q_0/A, depends on the texture of the surfaces, their cleanliness, their dryness, their temperatures and so on; all of which may be varying with time. But even so, a considerable reduction in average frictional charges should be possible.

Action of Acetylcholine on Rabbit's Auricles in Relation to Acetylcholine Synthesis

When the heart is removed from a freshly killed rabbit, the auricles can be dissected and put in a bath of Tyrode solution at 28° C. in which they continue to beat. The addition of acetylcholine to the bath slows the rate and diminishes the amplitude of the contractions.

After 24–36 hr., the auricles stop beating. The addition of acetylcholine to the bath at this point can restart the contractions, and further additions may increase the rate and amplitude. If the acetylcholine is removed without delay, the beat stops again; once, however, spontaneous activity is fully developed, removal of the starting dose does not arrest the beat, but it continues for an hour or more. Thus when the auricle stops beating, it appears to require acetylcholine in order to resume activity, which is then maintained. We have found a close correspondence between the functional state of the auricles and enzymic activity present in them. If an acetone-dried powder is prepared from auricles, it synthesizes acetylcholine in the conditions described for brain tissue by Feldberg and Mann[1]. The average figure for freshly excised auricles was 40 μgm. acetylcholine per gm. acetone powder per 75 min. We found that auricles which had stopped beating after 24 hr. in the bath lost most of their synthesizing power, the average figure being 15 μgm. per gm. Auricles which resumed activity after the addition of acetylcholine to the bath regained their synthesizing power, the average figure being 37 μgm. per gm.

The indication given by these figures of a connexion between activity in the living tissue and power to synthesize acetylcholine was borne out by observations of the effect of acetylcholine on its synthesis. Addition of acetylcholine to a powder (5–80 μgm. per gm. powder) from fresh auricles reduced the acetylcholine synthesis to 30 per cent of its control value. On the other hand, addition of acetylcholine to a powder from stopped auricles increased the acetylcholine synthesis to more than twice the control value.

Thus the action of acetylcholine is inhibitor when applied to auricular tissue in which the rate of synthesis is high; it inhibits the beat and it depresses the synthesizing power. On the other hand, the action of acetylcholine is motor when applied to auricular tissue in which the rate of synthesis is low; it can start the beat and it augments the synthesizing power.

Failure of Antihistamine Drugs to Inhibit Hyaluronidase *in vitro*

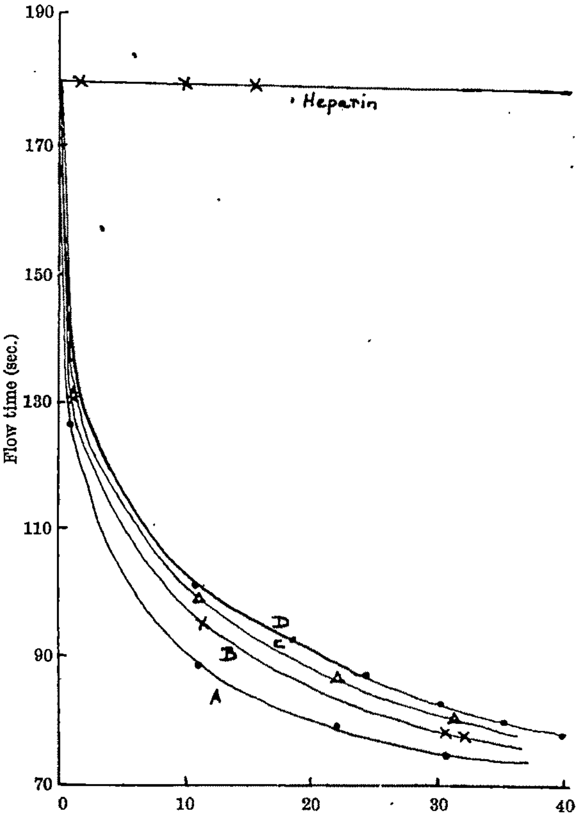
Mayer and Kull[1] have demonstrated that 'Pyribenzamine' and 'Antistin' counteract the spreading effect of hyaluronidase, and have claimed, therefore, that these antihistamine drugs exhibit a strong anti-hyaluronidase action. In view of the failure by Swyer[2], using an *in vitro* technique, to confirm a similar claim by Guerra[3,4] with respect to a supposed anti-hyaluronidase property of salicylates, it was decided to investigate the effect *in vitro* of various concentrations of some antihistamine drugs upon the hyaluronidase system.

Hyaluronidase preparations were obtained from rabbit and rat testis by a modification of the method of Kass and Seastone[5]. Enzymatic activity was measured in a No. 1 suspended-level viscometer. All estimations were carried out in a thermostat at 34° C.; this temperature was chosen because the work described here is part of a study of related problems in skin.

Viscosity reduction curves were obtained by a modification of the method of McClean and Hale[6], the flow-time of a mixture of 18 ml. buffer-substrate (4 vol. 0·12 per cent w/v aqueous hyaluronic acid and 1 vol. McIlvaine's citric acid–posphate buffer *p*H 7·0 containing 3·5 gm. sodium chloride/litre), 1 ml. buffer (or anti-histamine drug) and 1 ml. of testis extract, being measured at 2, 10, 20 and 30 min. after mixing. Prior to mixing, the solutions were filtered through a sintered glass funnel of porosity *G*4, and brought to 34° C.

Solutions containing 0·003, 0·033 and 0·33 per cent of (1) 'Antistin', (2) 'Benadryl', (3) 'Pyranisamine' and (4) 'Pyribenzamine', buffered so that the *p*H of each fell within the range 6·8–7·2, were tested for possible anti-hyaluronidase activity. In no case was there any evidence of significant inhibition of the enzyme. The latter was completely inactivated in the absence of chloride by the addition of 3·8 units of heparin per ml. reaction mixture. The effects of varying concentrations of 'Benadryl' upon the enzyme system are shown in the accompanying graph.

The above findings, therefore, show that, under our conditions, these drugs have no direct anti-hyaluronidase activity. Mayer and Kull, however, were careful to point out that their *in vivo* effects may be the result of a non-specific process. The work of Hechter[7] on the mechanism of the spreading effect of hyaluronidase in skin suggests, indeed, that this may be the case. Swyer[8] has shown that histamine enhances the spreading effect of hyaluronidase, and Mayer and Kull's findings might, therefore, be due to the action of these drugs on traces of histamine released during the intradermal injection of the spreading factor.



A, enzyme alone; *B*, enzyme in presence of 0·33 per cent 'Benadryl'; *C*, in presence of 0·003 per cent 'Benadryl'; *D*, in presence of 0·033 per cent 'Benadryl'

Our thanks are due to Messrs. Glaxo Laboratories, Ltd., for a gift of hyaluronic acid, to Messrs. Parke, Davis and Co., Ltd., Messrs. May and Baker, Ltd., and Ciba Laboratories, Ltd., for gifts of 'Benadryl', 'Pyranisamine' and 'Pyribenzamine', and 'Antistin', respectively. We would also like to thank Prof. R. H. S. Thompson for his help and encouragement.

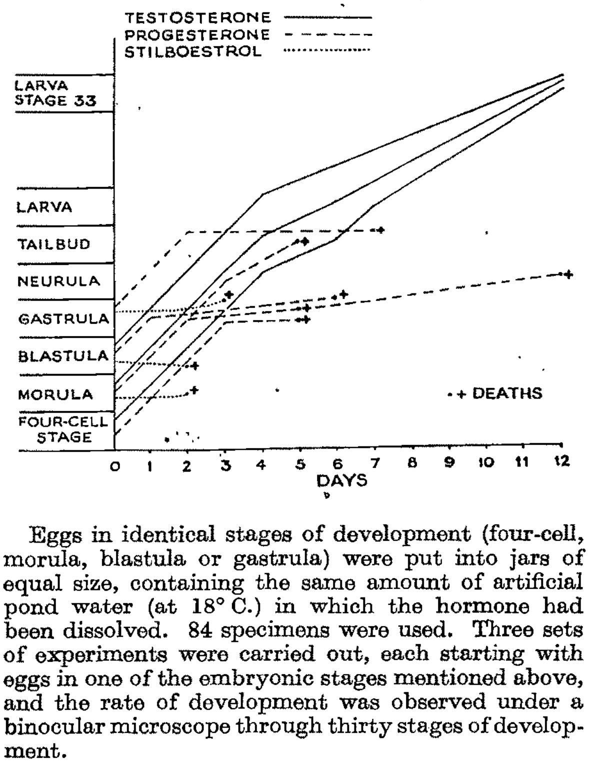
Differences in the Action of Steroids on Amphibian Embryos

In addition to their actions on the sexual organs, the steroids have some characteristic effects on cellular division. Von Möllendorff[1] showed that the frequency of mitosis in tissue cultures of fibrocytes is influenced by alcoholic solutions of 1 : 10,000 to 1 : 5,000,000 testosterone. G. Töndury[2] demonstrated that abnormal mitotic divisions may be produced in amphibian ova by alcoholic solutions of 1 : 100,000 to 1 : 1,000,000 testosterone, œstriol, œstradiol and stilbœstrol.

A study of amphibian embryos has revealed that steroids may retard the rate of development to a varying extent. The following experiments deal with the actions of equal concentrations (1 : 100,000) of testosterone, progesterone and stilbœstrol on the developing amphibian embryo (*Triton tæniatus*).



Eggs in identical stages of development (four-cell, morula, blastula or gastrula) were put into jars of equal size, containing the same amount of artificial pond water (at 18° C.) in which the hormone had been dissolved. 84 specimens were used. Three sets of experiments were carried out, each starting with eggs in one of the embryonic stages mentioned above, and the rate of development was observed under a binocular microscope through thirty stages of development.

Testosterone treatment. Embryos in the four-cell stage develop into a tail-bud stage on the fifth day. The morula stage becomes a blastula in 24 hr. and a gastrula in another 24 hr. Normal young larvæ (stage 33) develop in a fortnight. Development from the blastula stage is normal.

Progesterone treatment. Embryos in the four-cell stage develop into gastrulæ on the fifth day but do not develop further; they die on the seventh to the ninth day, during the process of gastrulation (stage 10–12).

The rate of development of the morula is retarded; it develops into a blastula only after two days. Gastrulation occurs on the third day, but most of the gastrulæ die during the process of gastrulation. The few that develop into neurulæ die on the twelfth to thirteenth day.

A blastula develops into a gastrula in 24 hr., but usually dies without further development after four to five days. A few pass through the neurula stage and die later as tail-bud stages. Gastrulæ also pass through the neurula stage and die as tail-bud stages after seven days.

Stilbœstrol treatment. No further development occurs in embryos which began the experiment in the morula, blastula or gastrula stages, and they die after two to three days.

These experiments show that while testosterone does not affect the development of common newt embryos, stilbœstrol prevents all development. Treatment with progesterone prevents complete development, the embryo dying during gastrulation or in the limb-bud stages.

Acetate as a Possible Precursor of Ruminant Milk Fat, Particularly the Short-Chain Fatty Acids

The origin of the short-chain fatty acids (C_4—C_{14}) of milk fat has been the subject of much speculation; some believe they originate by degradation of long-chain acids[1,2], others that they are synthesized from carbohydrate[3]. Their occurrence in appreciable quantities only in the milk fat of herbivores, more particularly ruminants[4], may be significant in the light of the fact that considerable quantities of acetate are produced in the rumen and absorbed into the blood[5]. These considerations, together with the demonstration that the body can build fatty-acid chains from acetate[6], suggested in 1945 that acetic acid might be the precursor of a portion of the milk fat, especially the short-chain acids[7].

In 1946 a fruitless attempt[8] was made to verify this theory by intravenous infusion of acetate into lactating goats during inanition, when the short-chain acids of the milk fat are much diminished. These negative results, and others in the cow[9], were probably due to avid utilization of the intravenously administered acetate by the fasting tissues, for ex-

† Significantly greater than unity ($P = 0·03$).

ample, the heart[10], so that adequate blood-levels were not maintained. *In vitro* experiments with mammary gland slices have now provided what we believe to be the first evidence in favour of the new theory of the origin of milk fat (see accompanying table).

Lactating mammary gland slices from all non-ruminants studied—rat[11], mouse, rabbit and guinea pig—have given a high respiratory quotient (measured as before[11]) in the presence of glucose, indicating the probable formation of fat from carbohydrate; on the other hand, the respiratory quotient for slices from the goat (and cow) is well below unity. With acetate as substrate, however, the situation is reversed, goat (and cow) gland now giving a respiratory quotient greater than unity, whereas the rat (and mouse) mammary gland do not appear to utilize acetate. The mammary tissue of the ruminant thus appears to be adapted for metabolizing acetate; and can not only oxidize it, but also, as indicated by the high respiratory quotient *in vitro*, can probably utilize it for fat synthesis, in this respect differing from other mammals, exemplified by the rat, which appear to require carbohydrate as substrate for fat formation. These results are consistent with the theory that in ruminants part of the milk fat is synthesized from acetate (this would explain the high udder respiratory quotient *in vivo*[3,11]); and if this is so, it seems very likely that the short-chain acids in particular arise in this way.

Criteria of Relationship between Plant Virus Strains

IT is now generally recognized that cross-protective power in the host plant, and serological relationship, are two of the most satisfactory criteria for establishing relationship between plant viruses.

In spite of an early observation by Smith[1], it is usually considered that if two viruses are related strains, then one strain will protect a plant completely from infection by a second strain, provided that the plant is fully infected with the first strain before inoculation with the second.

In experiments in *Datura tatula* and tobacco with six mottle type and four ring-spot type strains of potato virus *X*, it was found that four of the mottle strains protected completely against all the ring-spot strains. However, with two strains of the mottle type (*B* from Duke of York potato[2] and *TBRX* from tomato[3]), necrotic local lesions and systemic necrosis developed following inoculation with any of the ring-spot strains used. However, symptoms were not as severe as in the healthy controls inoculated with the ring-spot strains.

The same set of ten strains was also examined by the serological cross-absorption technique. Six of the strains were indistinguishable by the method used. Two strains had been isolated from the same potato plant, one a symptomless and one a ring-spot type isolated from Salaman's X^h culture[4]. These two strains were serologically indistinguishable, but possessed an antigenic fraction not possessed by any of the other eight strains. Thus, in this case, serological relationship was correlated with source of origin rather than symptom type.

TBRX and *B*, the two strains that did not give complete protection in the host, differed considerably in the serological tests from any of the other strains. They each had a strain-specific antigenic fraction and also shared a fraction not possessed by any of the other eight strains tested.

Thus, within the group of ten strains tested, there was a correlation between serological relationship and the degree of protection afforded in the host plant.

Infectious Chlorosis of Bananas in Colombia

A DISEASE probably identical or closely allied to the 'infectious chlorosis' or 'heart rot' of bananas, of a virus nature, has recently been found in Cauca Valley, on the Pacific side of Colombia, South America, and is now being studied by the staff of the Agricultural Experimental Station of Palmira.

This is a new record of the disease, previously known, in America, in the islands of Guadeloupe and Haiti[1]. Australian and African records have been reported by Wardlaw[2].

This is also the second time that a virus disease of cultivated plants has been found in Hispaniola Island (Haiti and Dominican Republics) and Cauca Valley, Colombia. I have already published previous records of a disease of the cacao tree of the same geographical distribution[3].

The features of this banana disease coincide with the symptoms described by Magee, Morwood and Wardlaw, with the exception of linear spots (from midrib to margin), which are frequently brown or reddish, instead of chlorotic. This symptom appears to be correlated with the presence of anthocyanin pigment in the leaves.

Head Presentation in Indian Chiroptera

MORE than a century ago, Daniell[1] described a head presentation during parturition in *Nyctalus noctula*. This record has been considered unique among bats, since later investigators have not been able to observe a similar birth. Breech presentation has been considered to be the usual rule in Chiroptera, following the observations of Rollinat and Trouessart[2] on *Myotis myotis* (called by them *Vespertilio murinus*), Sherman[3] on *Myotis austroriparius* and more recently by Wimsatt[4] on *Myotis lucifugus* among the Vespertilionidæ, and Blake[5] in a Phyllostomid bat (*Erophylla planifrons* ?).

Anyone who reads Daniell's account might be struck by the novelty of such a birth. I had opportunities of witnessing in detail parturition in the Indian short-nosed fruit bat *Cynopterus sphinx sphinx* (Vahl.), and Schneider's leaf-nosed bat *Hipposideros speoris* (Schn.), and in both a head presentation appears to be characteristic. Daniell's observations on *Nyctalus noctula* does not seem, therefore, to be unique, and since the two species reported above belong to the two different sub-orders of Chiroptera, extended observations may reveal further instances in which head presentation may be the rule.

Semi-Squamous Epithelial Layer in the Frog

AFTER studying the existence of the semi-squamous epithelial layer in the gastric and intestinal mucosæ of different mammals, we were curious to know if a similar layer was present in the amphibians, and for the purpose of this investigation we chose the frog. In this animal it was found that the whole gastric and intestinal mucosæ, together with the gall bladder, were covered by this layer.

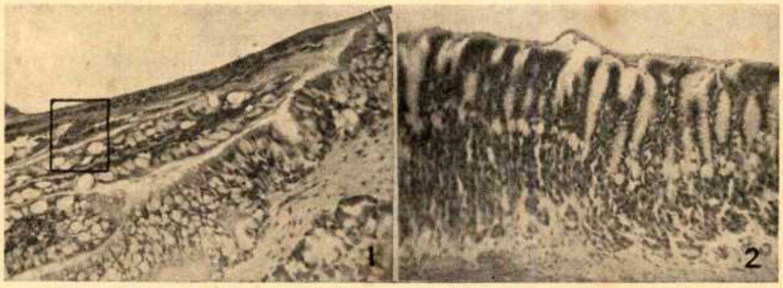

Fig. 1. Œsophagus of frog showing the ciliated tissue covered by the semi-squamous epithelial layer which contains a capillary. Fig. 2. Gastric mucosa of frog showing the layer

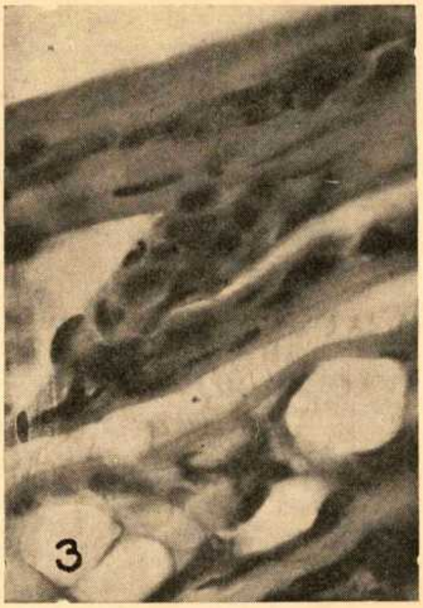

Fig. 3. High magnification of area outlined by rectangle in Fig. 1 showing details of the ciliated tissue covered by the semi-squamous epithelial layer containing a capillary

Investigations were also made to discover if the ciliated tissue in the œsophagus and pharynx of the frog was covered by the layer, as it has already been shown that the respiratory mucous membrane of mammals is protected by this structure. The same can be said of the ciliated tissue present in the Fallopian tubes, although this is rather more difficult to demonstrate because of the difficulty in opening the tubes without destroying the layer. It was logical to expect, therefore, that the semi-squamous epithelial layer should cover the ciliated tissue of the frog.

When this animal is used for the purpose of demonstrating the movement of the ciliated tissue, the layer is always removed beforehand as so-called mucus; but after carefully fixing the mucous membrane of the œsophagus and pharynx by the method of formalin vapour fixation, we were able to show not only that the ciliated tissue is covered by a similar layer to that found in the ciliated respiratory mucous membrane of mammals, but also that there were capillaries present at the top of this tissue.

It is borne in mind that these observations are against the accepted ideas of the physiological mechanism of protection by the ciliated tissue, but in the light of these investigations this supposed function obviously requires some revision.

My thanks are due to Prof. W. Schlapp, of the Department of Physiology, University of Manchester, for the supply of frogs, and to Mr. C. H. Butcher for technical assistance.

Taste Blindness of Japanese

It is well known that the strongly bitter taste of phenyl-thiourea is not noticed by some persons. It is said that 30 per cent of persons of white race do not recognize the taste. The result of tests on Japanese is given below:

Age	No. of persons examined	No. of 'non-tasters'	Percentage of 'non-tasters'
6–10	65	27	42
11–15	133	48	36
16–20	345	72	21
21–25	96	16	17
26–	277	48	17
Total	916	211	23

The percentage of non-tasting persons is obviously smaller. It depends on the age, but is independent of the sex. In respect of inheritance, we have few data to discuss, but so far have found no 'tasting' child born of 'non-tasting' parents.

Composition of the Gum of *Sterculia setigera*: Occurrence of D-Tagatose in Nature

The method of paper partition chromatography provides a simple micro technique for the separation[1] and estimation[2] of mixtures of reducing sugars, such as result from the hydrolysis of complex polysaccharides. It is possible to obtain an indication of the identity of the separated sugars from a comparison of their *Rg* values[1,3] and their colour reactions when heated with a solution of naphthoresorcinol in 12 per cent hydrochloric acid[4,1], but in some instances the results are inconclusive. For example, fructose (*Rg* 0·13), sorbose (0·11) and tagatose (0·13) possess very similar *Rg* values and all give a characteristic red colour with the naphthoresorcinol reagent, and they cannot, therefore, be identified by these properties alone. The difficulty has been overcome by use of a column of powdered cellulose[5], on which it is possible to separate by partition chromatography sufficiently large quantities of the sugars to permit of their identification in the usual way by determination of physical constants and the formation of characteristic derivatives.

In a study of the gum exudate of the tropical tree *Sterculia setigera*, we have applied these methods to the analysis of the mixture of sugars produced by acid hydrolysis of the polysaccharide.

The gum shows exceptional stability to acids, requiring such drastic conditions for complete hydrolysis that the reaction is accompanied by much degradation of the sugars. Partial hydrolysis of the gum, however, gave, with little degradation, a mixture of sugars and a degraded material which contained the uronic acids. After hydrolysis the free sugars were separated from the uronic acid portion, the properties of which corresponded to those of a trisaccharide containing two D-galacturonic acid residues and a sugar residue, probably mainly L-rhamnose. The chief components of the non-acidic portion were D-galactose, L-rhamnose and a ketose, which, from its properties, could be fructose, tagatose or sorbose. A portion of the sugar mixture (1·6 gm.) was separated on a column of powdered cellulose using as the mobile phase a solution of *n*-butanol saturated with water. After removal of solvent, two of the fractions crystallized spontaneously, and pure specimens of D-galactose and L-rhamnose hydrate were obtained. D-Tagatose was obtained in crystalline form from an intermediate fraction after oxidation of the accompanying aldose to the aldonic acid, which was removed as the barium salt. This sample of D-tagatose from *Sterculia setigera* gum was identical with a synthetic specimen kindly sent to us by Prof. T. Reichstein. Its identity was confirmed by an X-ray comparison of the crystals of the naturally occurring and synthetic sugar. We are indebted to Dr. T. Malkin for these results.

Fraction	Weight (in mgm.)	$[\alpha]_D$ in water	*Rg* values of sugars present	Sugars present
I	15	12°	0·385	Ketose
II	413	9·4°	0·30	L-Rhamnose
III	145	8·0°	0·17; 0·13	Aldose and D-tagatose
IV	373	34°	0·17; 0·13; 0·07	Aldose, tagatose and D-galactose
V	640	80·5°	0·07	D-Galactose

Fraction I contains a ketose which, in view of its high *Rg* value, is in all probability a methyl pentose derivative, and fraction III contains a small quantity of an unidentified aldose. The occurrence of D-galactose and L-rhamnose residues in a plant gum is not unusual, but the presence of D-tagatose in quantity is of particular interest since this ketose has not hitherto been reported as a constituent of any natural product. Its isolation illustrates the power of the new methods of analysis, and it is clear that re-examination of many plant and animal products will be required in order to ascertain whether sugars are present which have hitherto escaped detection.

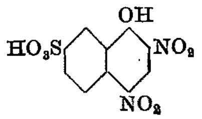
Adsorption Complexes of α-Zinc Hydroxide

In numerous communications, Feitknecht has described the preparation and structures of the basic salts and hydroxide of zinc. Particular reference is made in this communication to the so-called α-form of zinc hydroxide ($Zn(OH)_2$), to which Feitknecht[1] has ascribed a partially random structure, consisting of an assemblage of parallel layers, packed together without any further regularity. The analogy with the structures of the natural clay minerals montmorillonite and halloysite suggested to one of us (D. M. C. M.) that it would be of interest to see if the α-hydroxide shows the same type of interlayer adsorption as these clays[2]. This appeared likely, because Feitknecht[3] had shown that certain anionic dyestuffs are adsorbed on the α-zinc hydroxide, either by incorporating them in solution during the precipitation, or by shaking it with a solution of the dyestuff.

We have been able to prepare a stable complex of α-zinc hydroxide and the I.C.I. dye Naphthol Yellow



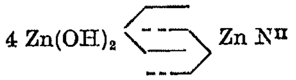
under well-defined conditions, which gives, in the unwashed state, a sharp basal spacing of 24·4 A. A single washing with either water or alcohol is sufficient to reduce this to an equally strong reflexion at 19·6 A. with four orders, which is stable to at least ten washings with alcohol or water, or even 0·001 *N* sodium hydroxide in alcohol. This is referred to below as the 'primary' complex.

Similar attempts to incorporate simpler non-ionized molecules (for example, glycerol) in the α-zinc hydroxide have failed. The analogy with the clay complexes thus appears to break down at this point.

However, it occurred to one of us (O. T.) that the more marked layer structure of the primary complex (clearly shown by the X-ray photographs) may make it more amenable to the adsorption of neutral organic molecules, thus forming 'secondary' complexes with increased basal spacings. Several such complexes, of which a small selection is listed in the accompanying table, have been investigated, using the same technique as has been used by MacEwan[2] with the clay mineral complexes. With the nitriles (except acetonitrile), a preliminary heat treatment was necessary to form the complex.

Substance adsorbed	d_{001} in A.	Δ in A. ($= d_{001} - 19{\cdot}6$)
Water	30·7	11·1
Methyl alcohol	27·8	8·2
Ethyl alcohol	30·8	11·2
Ethylene glycol	29·6	10·0
Glycerol	30·1	10·5
Acetonitrile	23·7	4·1
Propionitrile	25·1	5·5

On the analogy of the constitutional formula assigned by Feitknecht[4] to the basic zinc chloride II, the zinc and carbon contents of the (α-zinc hydroxide)–(Naphthol Yellow) complex agree quantitatively, within the limits of experimental error, with the formula



(in Feitknecht's[5] notation), where N^{II} is the divalent anion of the dye. A comparison of the calculated surface areas of the unit cell of α-zinc hydroxide and the planar dye molecule, together with the observed dye content of the primary complex, suggests that four layers of the dyestuff, lying flat, are held between consecutive layers of hydroxide. This is also in accord with the calculated thickness of the dye molecule, and the observed *c*-spacing of the primary complex.

The extra space taken up by the neutral organic molecules in the secondary complexes suggests that they form layers as in the clay mineral complexes, but the numbers of these layers appear to be different from those in the latter. This is probably due to differences in the actual mechanism of binding; in these 'secondary' complexes the additional molecules may be bound to the organic component of the primary complex rather than to the hydroxide layer. If this is so, it should be possible to prepare complexes presenting surfaces of different natures by employing anionic dyestuffs, the anionic portions of which vary in structure and lie within certain limits with regard to their size. The problem clearly requires a detailed examination, which is now being undertaken, and will form the subject of a later communication.

Prof. Feitknecht, who has seen this communication, informs us that he has since sent a communication entitled "Basische Salze organischer Säuren mit Schichtenstruktur" to *Experientia* (in the press).

We wish to thank Prof. W. Feitknecht for informing us, before publication, of certain of his results, and Messrs. I.C.I., Ltd. (Dyestuffs Division), for free gifts of materials. One of us (O. T.) wishes to thank the Department of Scientific and Industrial Research for a grant which has made his contribution possible.

Reduction Potentials of Conjugated Systems

WAZOWNEK and his collaborators have studied the reduction of conjugated systems at the dropping mercury electrode[1]. They have brought forward evidence to support the following mechanism :

$R + e^- \rightarrow R^-$ (reversible, potential-determining).
$R^- + e^- \rightarrow R^=$ (irreversible).
$R^= + 2H_2O \rightarrow RH_2$ (irreversible, fast).

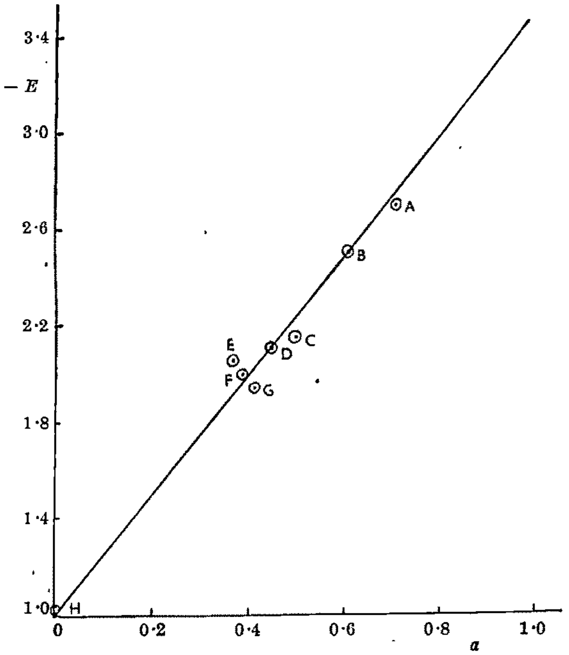
This holds in the case of a molecule such as styrene, having a bond which is essentially double. In the case of aromatic molecules, however, the reversible, potential-determining step may consist in the addition of two electrons.

Hückel[2] has applied the molecular orbital method to a discussion of the alkali metal salts of aromatic compounds. He points out the qualitative relationship between the resonance energy in the lowest unoccupied molecular orbital (which may accept one or two electrons) and the ease of addition of the alkali metals. The present communication shows how this concept may be applied to discuss the reduction potentials of conjugated systems.

The reversible potential is given by

$$-nEF = \Delta H - T\Delta S,$$

where ΔH is the heat content and ΔS the entropy change, n being the number of electrons involved. Now ΔH may be related to the energy required to place one or two electrons in the lowest unoccupied orbital of the molecule, and so there should exist a linear relationship between E and a, where a is the coefficient of the molecular orbital resonance integral in the expression for the energy of the lowest unoccupied orbital. A plot of E against a is shown in the accompanying figure. The approximately linear relationship between E and n verifies the postulated mechanism. Further evidence may be obtained by considering the overall equilibrium between R and RH_2. If this were the potential-determining process, there should exist a relationship between the potential and the difference in resonance energies of RH_2 and R. No such relationship exists.



The reduction potentials of some hydrocarbons as a function of *a*. The substances referred to are: *A*, diphenyl; *B*, naphthalene; *C*, stilbene; *D*, pyrene; *E*, tetraphenyl ethylene; *F*, 1:4 diphenyl butadiene; *G*, anthracene; and *H*, triphenyl methyl.

On the basis of the above theory, the difficulty of reduction of an isolated double bond and of benzene may be understood, for in these cases a very large negative potential would be required. In the former case polarographic reduction differs from catalytic reduction[3].

Reduction by dissolving metals may also be discussed on these lines. Two possible mechanisms exist in this case,

$$R + H^+ \rightarrow RH^+$$
$$RH^+ + 2e \rightarrow RH^-$$
$$RH^- + H^+ \rightarrow RH_2$$

as suggested by Burton and Ingold[4]; or

$$R + 2Na \rightarrow R^= + 2Na^+$$
$$R^= + 2BH \rightarrow RH_2 + 2B^-$$

as proposed by Ziegler[5]. In addition, there is the possibility in the former scheme of the consecutive addition of the electrons. Two problems arise in these cases, namely, the ease of reduction, and the products formed. The former may be discussed along the lines suggested above. For a discussion of the latter, the electron structure of RH^- and $R^=$ will have to be examined. The position of addition of the protons will be determined by the charge distribution of the ions.

It is hoped shortly to publish a fuller account of this work.

Electron Distribution in Substituted Styrenes Derived from Infra-Red Spectra

IN a recent communication[1], it was pointed out that the abnormalities in the physical properties and polymerization characteristics of vinyl mesitylene could be ascribed to steric hindrance by the methyl groups in the ortho positions; it was mentioned that a study of the infra-red spectra of the styrenes revealed differences that supported the hypothesis that this 'blocking' affected the electronic structure.

In the light of recent developments in the normal co-ordinate treatment of group vibrations[2], a more precise interpretation of the infra-red results may now be given. The key δ_{CH_2}-band[2] in styrene lies at 913 cm.$^{-1}$. The shifts from this frequency in *m*- and *p*-methyl styrenes and in 5-vinyl-pseudocumene have values of −5, −4 and −5 cm.$^{-1}$ respectively; the shift in vinyl-mesitylene is + 12 cm.$^{-1}$. The absolute magnitudes of δ_{CH_2} indicate that there is a resultant negative charge on the terminal carbon atom of the vinyl group in all five compounds, which will be associated with *m*-substitution in the phenyl nucleus. The methyl groups in the three compounds with negative increments give rise to a small additional negative charge over and above that due to conjugation with phenyl; presumably the normal effect found in propylene[2] is transmitted via the conjugated system. In vinyl mesitylene, the relative instability of planar structures inhibits the resonance effect, and, in spite of the presence of three methyl groups, the increment is positive, though the electron distribution is still such as to give rise to *m*-direction.

I wish to express my gratitude to Trinidad Leaseholds, Ltd., for allowing me access to the infra-red data used in this note.

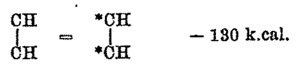
Thermochemistry of Acetylene and Allylene and the Valency of Carbon

RECENTLY, Long and Norrish[1] have shown that when the energy associated with the tetravalent state of carbon is systematically taken into account it is possible to bring order into the thermochemistry of carbon. They support the value of 190 kcal. for the latent heat of sublimation of graphite into free atoms at the lowest energy-level of tetravalence (^5S), and 125 k.cal. for the latent heat of sublimation into the divalent (^3P) state. Thus, the energy obtained in the $^5S \rightarrow {}^3P$ conversion is 65 kcal.

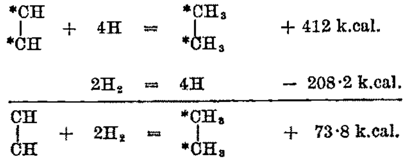
The purpose of the present note is to show that if we assume that in acetylene and derivatives there are two carbon atoms in the divalent state associated with each triple bond, and compute the heat of hydrogenation using this assumption together with the values of Long and Norrish, the result is in striking concordance with the experimental values.

Heat of hydrogenation of acetylene to ethane. Taking the value for the C—H bond energy in ethane[1], and writing *C for tetravalent carbon and C for divalent carbon, we have, assuming divalent carbon in acetylene:



$$\begin{array}{c}\mathrm{CH}\\|\\\mathrm{CH}\end{array} = \begin{array}{c}{}^*\mathrm{CH}\\|\\{}^*\mathrm{CH}\end{array} \qquad -130\ \text{k.cal.}$$

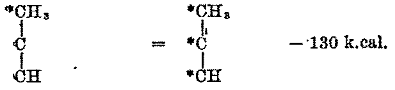
The first step consists in the excitation of the two carbon atoms:



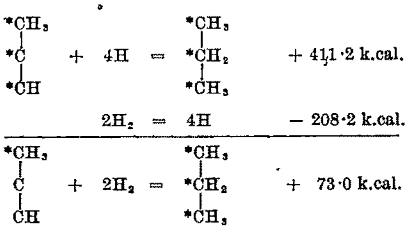
$$\begin{array}{lcl} \begin{array}{c}{}^*\mathrm{CH}\\|\\{}^*\mathrm{CH}\end{array} + 4\mathrm{H} & = & \begin{array}{c}{}^*\mathrm{CH_3}\\|\\{}^*\mathrm{CH_3}\end{array} \qquad +412\ \text{k.cal.} \\ 2\mathrm{H_2} & = & 4\mathrm{H} \qquad -208{\cdot}2\ \text{k.cal.} \\ \hline \begin{array}{c}\mathrm{CH}\\|\\\mathrm{CH}\end{array} + 2\mathrm{H_2} & = & \begin{array}{c}{}^*\mathrm{CH_3}\\|\\{}^*\mathrm{CH_3}\end{array} \qquad +73{\cdot}8\ \text{k.cal.} \end{array}$$

The experimental value for this reaction is + 74·4 k.cal.

Heat of hydrogenation of allylene to propane. Again, using for the C—H bond energy in propane the value 102·8 k.cal.[1], and computing the heat of hydrogenation of allylene, we have:



$$\begin{array}{c}{}^*\mathrm{CH_3}\\|\\\mathrm{C}\\|\\\mathrm{CH}\end{array} = \begin{array}{c}{}^*\mathrm{CH_3}\\|\\{}^*\mathrm{C}\\|\\{}^*\mathrm{CH}\end{array} \qquad -130\ \text{k.cal.}$$



$$\begin{array}{lcl} \begin{array}{c}{}^*\mathrm{CH_3}\\|\\{}^*\mathrm{C}\\|\\{}^*\mathrm{CH}\end{array} + 4\mathrm{H} & = & \begin{array}{c}{}^*\mathrm{CH_3}\\|\\{}^*\mathrm{CH_2}\\|\\{}^*\mathrm{CH_3}\end{array} \qquad +411{\cdot}2\ \text{k.cal.} \\ 2\mathrm{H_2} & = & 4\mathrm{H} \qquad -208{\cdot}2\ \text{k.cal.} \\ \hline \begin{array}{c}{}^*\mathrm{CH_3}\\|\\\mathrm{C}\\|\\\mathrm{CH}\end{array} + 2\mathrm{H_2} & = & \begin{array}{c}{}^*\mathrm{CH_3}\\|\\{}^*\mathrm{CH_2}\\|\\{}^*\mathrm{CH_3}\end{array} \qquad +73{\cdot}0\ \text{k.cal.} \end{array}$$

The experimental value for this reaction is 71·1 k.cal.

Phase Characteristics of Exponential Functions

A PHASE relation familiar to students of applied mathematics exists between a simple harmonic oscillation and its derivative. Similar relations exist between exponential functions and their derivatives, but these do not appear to be well known, and are not described in any text-book I have been able to consult: reference is made in some text-books to the imaginary period of the exponential function.

The simplest relation of this type is expressed by

$$\dot{x}_2 = -kx_1,$$

where $x_1 = x(t_1)$, $x_2 = x(t_2)$, and $t_2 - t_1 = c$. Any exponential solution of this equation represents a subsidence, a damped oscillation, a harmonic oscillation, or an unbounded oscillation. The general solution is a sum of such components, and the value of $\varphi = kc$ determines which types may appear in it. In particular, there can be no unbounded component unless $\varphi > \pi/2$; no harmonic component unless $\varphi = \ldots -\frac{3\pi}{2}, \frac{\pi}{2}, \frac{5\pi}{2} \ldots$; and no steadily decreasing component unless $0 < \varphi \leqslant e^{-1}$.

When $e^{-1} < \varphi < \pi/2$, an expression of the form

$$x = X \exp(-At) \cdot \frac{\sin}{\cos}(Bt \pm \theta)$$

may be the solution. If then the interval c is less than the periodic time $2\pi/B$, a derived expression is

$$\varphi = \frac{\gamma}{\sin\gamma} \exp\left(\frac{-\gamma}{\tan\gamma}\right),$$

where $\tan\gamma = B/A$.

The equation

$$\dot{x}_2 = -kx_1$$

may also be regarded as forecasting the behaviour of $x(t)$ for $t \geqslant c$ from its values for $0 \leqslant t < c$. For example, if $x = X$, for $0 \leqslant t < c$, successive integration shows that

$$x = X\left\{1 - \varphi\left(\frac{t}{c} - 1\right) + \frac{\varphi^2}{2!}\left(\frac{t}{c} - 2\right)^2 \ldots \ldots + \frac{(-\varphi)^{n-1}}{(n-1)!}\left[\frac{t}{c} - (n-1)\right]^{n-1}\right\},$$

for $$(n-1)c \leqslant t < nc.$$

This is steadily decreasing only if

$$\varphi \leqslant e^{-1},$$

a fact which is used in the following example.

An air-force formation has been operating N aircraft, the maximum number that its resources suffice to maintain serviceable for an indefinite period, but holds in reserve, at t_0, X serviceable aircraft over and above N. It is intended to operate for a period every serviceable aircraft held. There is evidence that the rate of change of serviceability, $\dot{x}_2$ at t_2, will be proportional to the difference x_1 between N and $(N + x_1)$ the number operated at an earlier time t_1, so that $\dot{x}_2 = -kx$; if $k = 2$ per month, what may be the maximum value of $c = t_2 - t_1$ in months if there is to be no tendency for serviceability to fall below the continuously maintainable, N, level? Answer, c must be $\ngtr e^{-1}/2$ or 0·184 month.

The class of equations to which the above illustrations belong has been discussed generally by H. R. Pitt[1], to whom, and to R. McKinnon Wood and G. Silyn-Roberts, I am indebted for unpublished notes.

THE NATURE OF PENETRATING PARTICLES IN AIR SHOWERS

By Prof. L. JÁNOSSY and C. B. A. McCUSKER
Dublin Institute for Advanced Studies

Introduction

EXTENSIVE air showers consist mainly of electrons and photons, but contain in addition a small percentage of particles more penetrating than electrons.

The nature of these particles was recently discussed by Auger, Daudin, Fréon and Maze[1]; and independently by Broadbent and Jánossy[2]. Both groups came to the conclusion that the penetrating particles cannot be mesons of the ordinary type. Auger's group suggested that the penetrating particles are 'λ-mesons', that is, charged particles of elementary charge and mass about 3 m_e. Broadbent and Jánossy put forward the suggestion that the penetrating particles are 'heavy electrons', that is, electrons of mass about 10 m_e. The two suggestions are, of course, identical; both were, however, based on somewhat indirect arguments. Recent experiments, partly reported at the Bristol Symposium held last September, give additional support to the λ-meson or heavy electron hypothesis.

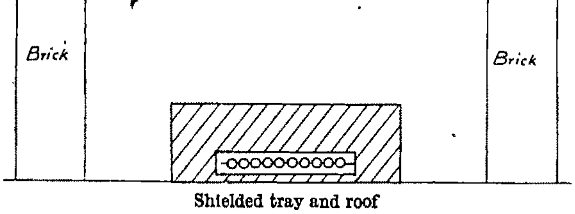
Recent Experimental Evidence

Miss Chowdhuri reported at the Bristol Symposium the following experiment. Air showers were recorded by means of fourfold coincidences. The set consisted of three unshielded counters in a horizontal plane and a tray of shielded counters near by; the tray was shielded by 15 cm. of lead. Fourfold coincidences were recorded both with and without a lead roof 1 cm. thick (supported by 1 cm. of iron) about 30 cm. above the top of the lead shield. The unshielded counters were placed at a sufficient distance from the shielded tray so as not to be affected by the roof. A considerable change of the rate of fourfold coincidences in the presence of the roof was noticed. The actual rates found are given in Table 1.

Table 1. Fourfold coincidences, rate per hour

With roof	0·263 ± 0·037
No roof	0·474 ± 0·053
Difference	0·211 ± 0·064

The above experiment was repeated and confirmed by us in Dublin. Threefold coincidences were recorded between two unshielded trays each of 750 cm.^{2} area and a shielded tray of 1,500 cm.^{2} area. The arrangement of the shielded tray and the roof are illustrated in the accompanying sketch. The roof was supported by 4 in. of wood resting on brick supports. The supports and the wood were left in position throughout the series. Measurements were carried out with various absorbers *A* placed on top of the wood. The results obtained are given in Table 2.



Shielded tray and roof

Table 2

Absorber *A*	No. of coincidences	Rate per hour
No absorber	325	3·32 ± 0·18
20 gm./cm.^{2} brick	231	3·33 ± 0·20
1·7 cm. lead	380	2·53 ± 0·13

We see from Tables 1 and 2 that a thin lead roof reduces the number of penetrating extensive showers recorded, while a mass-equivalent brick roof shows no noticeable effect.

The above experiment can be interpreted, in our opinion, as follows:

(1) The penetrating particles in air showers are produced locally in the first few centimetres of lead.

(2) The penetrating particles are highly unstable and have a considerable chance of decay along the 50-cm. gap between roof and absorber. An apparent life of the order of 10^{-8} sec. is to be expected.

(3) While the thin lead roof shows a considerable effect, no noticeable effect is shown by a mass-equivalent brick roof. It must be concluded that the primaries of the penetrating particles are strongly absorbed in lead but not in the mass-equivalent of brick. This makes it virtually certain that the primaries of the penetrating particles are either electrons or photons or both.

(4) It may be added that this experimental evidence is incompatible with the view that the penetrating particles are produced by nucleons; nucleons would show similar effects in lead and brick roofs. Thus the present experiment further supports the view that the *local* penetrating showers which are produced by nucleons are qualitatively different from the extensive penetrating showers.

The above conclusions, with the exception of (2), were put forward previously by Jánossy and Broadbent[2] as a result of a detailed analysis of shower data.

It should be noted that conclusion (1) stands independently of whether (2) is admitted or not. Though we think it likely that the actual decrease of the shower-rate is caused by decay, this interpretation is not essential for the arguments below; if the decrease were to be explained by any other mechanism (for example, scattering in the roof), it would still be necessary to maintain that the penetrating particles are produced by photons in a thin layer of lead.

Z Dependence of the Production of Penetrating Particles

In discussing the nature of the penetrating particles in air showers, we may recall the experiments carried out by Cocconi and Festa[3], Mura, Salvini and Tagliaferri[4], and Chowdhuri[5]. Extensive showers were recorded in these experiments by counter trays all except one of which were unshielded. The shielded tray was covered alternately with lead only and with lead under an iron shield. As was pointed out by

Ferretti, the number of penetrating events recorded should be proportional to

$$k = \Phi\ (\text{prod}) \,/\, \Phi\ (\text{abs}), \qquad (1)$$

where Φ (prod) is the cross-section for the production of penetrating particles in the top layer of the shield, and Φ (abs) is the cross-section for the absorption of the primaries giving rise to penetrating agents. As shown above, the penetrating agents are produced either by electrons or photons; thus

$$\Phi\ (\text{abs}) \sim Z^2 \text{ per atom.}$$

The comparison of lead and iron absorbers has shown experimentally that Φ (prod) / Φ (abs) is independent of Z. Thus

$$\Phi\ (\text{prod}) \sim Z^2. \qquad (2)$$

Furthermore, it is found that $k \sim 1/50$, and therefore

$$\Phi\ (\text{prod}) \sim \frac{\Phi\ (\text{rad})}{50}, \qquad (3)$$

where Φ (rad) is the 'radiative cross-section'; that is, either the cross-section for *Bremstrahlung* or pair production.

Equations (2) and (3) are most remarkable. They show clearly that the penetrating radiation must be emitted in collisions in the Coulomb field of the nucleus; thus the conclusion can scarcely be escaped that the penetrating particles are either of the two following types:

(*a*) Particles somewhat heavier than electrons, created by photons by pair production.

(*b*) Neutral particles emitted by electrons as a kind of collision radiation.

If the latter hypothesis were assumed, it would be necessary to ascribe to the electron a charge which is the source of the neutral field. The neutral quantum could then be emitted by the electron accelerated in the Coulomb field. Hypothesis (*b*) is, however, rendered unlikely in view of the experiments of Broadbent and Jánossy, where penetrating agents are found to discharge frequently two covered trays (*m*) and (*b*) on top of each other.

We are therefore left with hypothesis (*a*) that penetrating particles in air showers are largely 'heavy electrons' or λ-mesons produced presumably by photons. We may add that the heavy electrons observed must have energies exceeding 200 MeV. as they are capable of penetrating 15 cm. of lead. If their rest energy is of the order of a few MeV., then the *proper life* is estimated to be of the order of $\tau \sim 10^{-11}$ sec.

This short life fully accounts for the absence of cloud chamber evidence (see, for example, Fretter[6]). A track which might possibly be a case of a decaying heavy electron is found in the left-hand bottom corner of a photograph of a penetrating air shower given by Jánossy, Rochester and Broadbent[7]. The particles penetrating a lead plate seen on the same photograph might very well be examples of heavy electrons.

The supposed short life of the heavy electrons throws more light on the analysis by Auger and co-workers[1]. This analysis shows that extensive showers when penetrating lead absorbers behave essentially differently from what is to be expected from cascades. On the other hand, the behaviour of extensive air showers in the atmosphere can be accounted for in terms of the cascade theory, as shown, for example, by Cocconi, Loverdo and Tongiorgi[8]. This discrepancy can be explained in terms of the instability of the heavy electron. The heavy electrons play an important part only in dense absorbers.

Estimate of the Mass of the Heavy Electron

The experiments described above, together with those reported earlier[1,2], seem to show conclusively that at least an appreciable fraction of the penetrating particles in air showers are different in nature from particles observed hitherto. The conclusion that these new particles are, in fact, heavy electrons must be taken only as a conjecture, supported by general theoretical arguments. It seems, however, worth while to show that the assumption of a heavy electron of suitable mass does not lead to contradictions.

In particular, it follows from general arguments that the ratio between the cross-section for production of heavy pairs and the cross-section for collision radiation of a heavy electron must be very nearly the same as the ratio of the corresponding cross-sections for ordinary electrons; we show in the following that the observed effects are compatible with this general assumption.

The cross-section Φ (prod) of equation (1) is the average cross-section for the production of a heavy pair per incident electron. We derive the actual probability for the production of a heavy pair in the following way.

An electron or photon of energy E incident on the absorber gives rise to cascades, and the total photon path-length of photons with energy exceeding E' is

$$t\ (E, E') = 0{\cdot}572\ E/E' \text{ cascade units.}$$

Assuming that the number of photons is 1·5 times the number of electrons in the shower, we have for the total photon path associated with one electron

$$2{\cdot}5\ t\ (E, E') = 1{\cdot}43\ E/E'.$$

The energy spectrum of the air shower can be represented by

$$dS\ (E) \sim \frac{E_c\, dE}{(E + E_c)^2} \quad E_c = 100 \text{ MeV.} \qquad (4)$$

(Mitra and Rosser, in the press; reported at the Bristol Symposium).

Thus the total path-length per incident electron in cascade units is

$$T\ (E') = \frac{1{\cdot}43}{E'} \int_{E'}^{E_1} \frac{E\, E_c\, dE}{(E + E_c)^2} =$$

$$\frac{1{\cdot}43\ E_c}{E'} \left\{ \log \frac{E_1 + E_c}{E' + E_c} - \frac{E_c\ (E_1 - E')}{E_1 + E_c} \right\} \qquad (5)$$

(E_1 is the upper limit of the validity of (4)).

The mean free path of a photon for giving rise to an ordinary pair is 1·35 cascade units; thus the probability P of a heavy pair being produced is about $0{\cdot}76\ T\ (E')\ K$, where $K \sim (m_e/m_h)^2$.

We have to consider the probability that a heavy electron discharges one of the shielded counters. The ionization loss in 15 cm. of lead (30 cascade units) is 200 MeV.; thus only heavy electrons with $E' >$ 200 MeV. need be considered. The probability of a heavy electron $E' > 200$ MeV. traversing the absorber of 30 cascade units is of the order of $\exp\ (-30\, K\ \alpha\ (E'))$, $30\, K$ being the thickness of the absorber in cascade units of the heavy electron; $\alpha\ (E')$ is a function derived from cascade theory, which has values somewhat less than unity for small energies and is decreasing for larger energies.

We have thus for the fraction k of penetrating particles

$$k = 0{\cdot}76\ T\ (200 \text{ MeV.})\ K \exp\ (-30\, K\ \alpha\ (E')).$$

Now putting $k = 1/50$ (equ. 3), $K = 1/30$, $\alpha = 1$, the equation requires $T(E') \sim 2 \cdot 0$. This value is reasonable; it is obtained from (5) by putting $E_1 \sim$ 6,000 MeV. Thus the experimental findings are roughly in accord with $K = 1/30$; that is, $m_h \sim 6m_e$. The above consideration is very rough; but it seems to show that the heavy electron hypothesis is not incapable of accounting for the experimental findings.

We are greatly indebted to Prof. W. Heitler for detailed discussions, and we are also indebted to Dr. T. Nevin for help during the experiments.

Note added in proof. After submitting this communication a photograph purporting to be that of a particle of mass $10\,m_e$ has been reported by Cowan (*Science*, November 12, 1948).

SIMULTANEOUS MEASUREMENT OF THE OPTICAL CONSTANTS OF METALS OVER A WIDE WAVE-LENGTH RANGE

By J. BOR and B. G. CHAPMAN
South-West Essex Technical College, London, E.17

THE optical constants of metals can be calculated from a knowledge of the ellipse of vibration which results from the reflexion of plane polarized light usually at an azimuth of 45° by a plane metallic surface. In the present method, this ellipse is determined by finding the ratio of the major and minor axes and the orientation of the major axis to the plane of incidence. It differs, however, from other methods using this principle in that the data from which the ellipse is obtained are produced on a photographic plate in the form of a thin vertical strip of variable intensity for each wave-length. A continuous source and a dispersing prism enable a record to be obtained simultaneously for the whole of the spectrum-range required.

The essentials of the optical system are shown in Fig. 1. The reflected elliptically polarized light passes through the rotator T, which consists of two prisms of right- and left-handed quartz in optical contact. Above the central plane the ellipse will be rotated clockwise; below, counter-clockwise. Fig. 2 indicates the relative orientations of the ellipse in the light emerging from the rotator. If the analysing nicol N is adjusted for plane polarized light, the vibration direction of which is vertical, then in the positions ACF the intensity will be a minimum, and in positions BEG a maximum. The square root of the ratio of these intensities gives the ratio of the axes. DD is the central plane, so that the orientation of the ellipse is given by

$$\theta = \frac{CD}{CF} \times 180°.$$

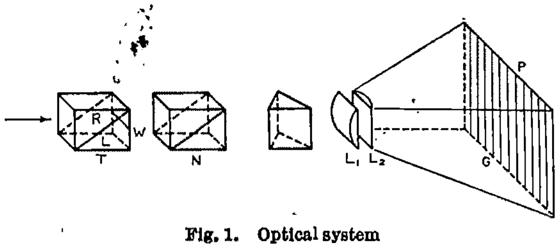

Fig. 1. Optical system

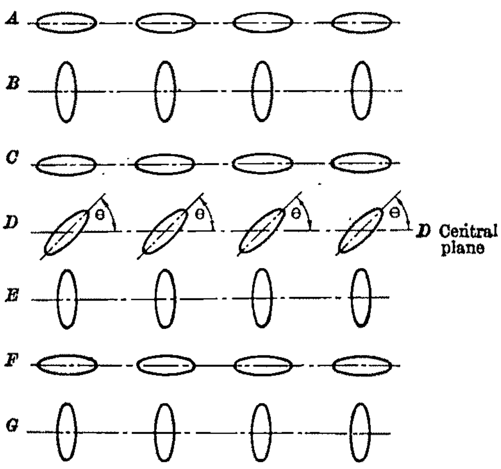

A, C, F, minima; B, E, G, maxima; $BC = AC$
Fig. 2. Relative orientations of the ellipse

A fiducial line consisting of a very fine wire W is placed immediately after the rotator and adjusted to be in the central plane. A plano-cylindrical lens L_1 produces at its conjugate focus P an image of the pattern of Fig. 2, modified by the analyser, and of the fiducial line, magnified in the vertical plane only. A second plano-cylindrical lens L_2 converges the light horizontally into a vertical strip of variable intensity in its focal plane P. Using white light and a prism, a spectrum crossed by a system of dark and bright bands together with the horizontal fiducial line is obtained on a photographic plate placed at P. By removing the rotator and analyser, which are mounted together, and placing in position a triangular aperture with base horizontal and its plane coincident with the fiducial line W, an exposure of graded intensity is obtained. In front of the photographic plate P, which can be moved horizontally in its own plane, a grid G is placed, consisting of alternate opaque and transparent strips. This enables the crossed spectrum and the comparison spectrum of graded intensity to be obtained, adjacent strips being of the same wave-length.

Fig. 3 shows the pattern obtained with aluminium, the exposure time for each spectrum, taken consecutively, being 40 sec. Microphotometric comparison of the maxima and minima against the adjacent graded intensity enables the ratio of the axes to be determined, while the distance between the fiducial line and the various maxima and minima gives the orientation of the ellipse. Since the time involved in obtaining the data for a wide wave-length region is so short, the method is clearly advantageous in that deterioration or change of the surface while observations are being made is avoided. So far as we are aware,[5] all existing methods of measuring the optical constants of metals require the use of monochromatic light, making the determination of a dispersion curve a lengthy process.

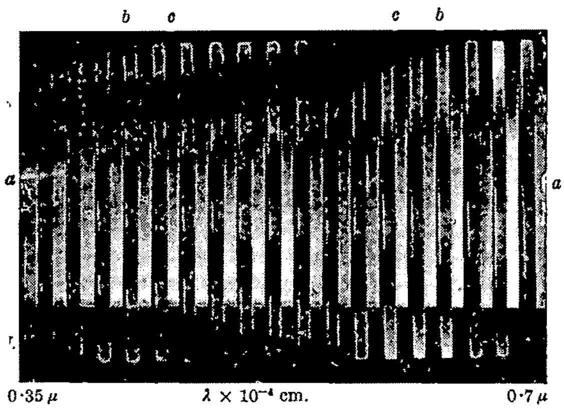

Fig. 3. (a) Fiducial line; (b) vertical bands of variable intensity; (c) adjacent graded intensity

Experiments have so far been carried out in the wave-length range 0·35–0·7 μ with gold and aluminium specimens of known dispersion (measured on the senior author's photo-electric apparatus[1]), and good agreement was obtained. The estimated accuracy is about 2 per cent, but improvements now being made are expected to increase the accuracy and reduce the exposure time.

One of us (B. G. C.) is indebted to the Department of Scientific and Industrial Research for the award of a maintenance grant.

GROUND SUBSTANCE OF THE MESENCHYME AND HYALURONIDASE

A CONFERENCE devoted to the "Ground Substance of the Mesenchyme and Hyaluronidase" was organised by Dr. F. Duran-Reynals with the co-operation of Dr. E. D. Goldsmith and was held during December 3–4 under the sponsorship of the New York Academy of Sciences.

The programme concerned itself with all phases of current research pertaining to acid mucopolysaccharides and hyaluronidase, the most important of the group of substances known as spreading factors. Histochemical, electron microscope, biochemical, bacteriological, endocrinological and clinical findings were reported.

Hyaluronidase is widely distributed in Nature. It is found in male germ cells, in pathogenic bacteria, such as streptococci and pneumococci, in insects, in fishes, and in the poison glands of several venomous reptiles. Although produced by such diverse organisms, the function of the enzyme is the same in all cases; but the results are totally different. The function of hyaluronidase is to attack the cementing mucoid substance of the connective tissue. By attacking this cementing substance, the enzyme 'dissolves' it and opens the way for any material which may penetrate the body with it.

Thus, the spreading factor associated with the male germ cells dissolves the cementing material surrounding the female germ cells and makes fertilization possible. (The adhesive quality of mucopolysaccharides of ovarian follicular fluid clumps the granulosa cells around the discharged ovum until acted upon by hyaluronidase from the sperm.) When the factor comes from a bacterium it facilitates invasive infection, and when hyaluronidase is injected with a therapeutic agent, it speeds and enhances the action of such agents.

The study of the action of the enzyme on the cement substance has served to explain an important factor in the mechanism of infection, namely, spreading in the organism of poisons or infectious agents. Equally it has provided a tool for the clinician, since it promotes the spreading of therapeutic substances in the organism. Infections may thus be fought with their own weapons.

The following papers dealing with more specific aspects were read at the conference.

The enhancement of the capacities for growth and invasion of a mouse transplantable squamous cell carcinoma by the local injection of hyaluronidase from testis (W. L. Simpson, Detroit Institute of Cancer Research).

The facilitation of absorption of subcutaneously injected lactate–sodium-glucose solutions with a diminution in pain. It should prove to be extremely useful in hypodermoclysis (C. L. Burket and P. Gyorgy, University of Pennsylvania).

Hyaluronidase enhances the penetration as well as the spreading of drugs. Further, it exhibits very low toxicity (J. Seifter, Wyeth Institute of Applied Biochemistry).

Hyaluronidase reported to be effective in the spreading of the anæsthetic action of local anæsthetics. Certain difficulties encountered in nerve block techniques in regions like the mandible may be overcome by the addition of hyaluronidase to the procaine–epinephrine mixture (C. H. Kirby, J. P. Looby and J. E. Ekenhoff, School of Medicine and Dentistry, University of Pennsylvania).

Dr. D. H. Sprunt (University of Tennessee) and Dr. M. Lurie (Henry Phipps Institute) emphasized the importance of the connective tissue ground-plasm in infection (tuberculosis, D. Lurie). Female sex hormone increases the turgidity of the connective tissue elements and reduces capillary fragility. Œstrogens retard the progress of tuberculosis, chiefly by reducing the permeability of the connective tissue, whereas gonadotrophin enhances the progress of the disease, primarily, by increasing the permeability. It is noteworthy that some years ago Thomas and Duran-Reynals accelerated the progress of tuberculosis with hyaluronidase.

Additional findings by Drs. F. Duran-Reynals, G. Van Wagenen, H. Bunting and J. Opsahl (Yale University School of Medicine) pertaining to the relationship between the œstrogens, adreno-cortical hormone and the ground substance and hyaluronidase were reported.

Drs. C. Ragan and K. Meyer (College of Physicians and Surgeons, Columbia University), in their report on the possible connexion between hyaluronidase and rheumatic diseases, disclosed that the pathogenesis of the rheumatic diseases is obscure. Apparently, the disease process is localized in the connective and particularly in the interfibrillar material, which is composed in part of one or both of the mucopolysaccharides—chondroitin sulphuric acid and hyaluronic acid. Many micro-organisms produce hyaluronidase; but only two, Group *A* and *C* hæmolytic streptococci, produce hyaluronic acid. The highest concentration of hyaluronic acid in the mammal is found in the synovial fluid (in the joint). In normal human joint fluid the hyaluronic acid exists in a highly polymerized form; in rheumatoid arthritis, the hyaluronic acid is depolymerized, and the extent of depolymerization varies with the activity of the disease process.

Dr. M. C. Chang and Dr. N. T. Werthessen (Worcester Foundation for Experimental Biology) took issue with the conclusions of Dr. Raphael Kurzrock to the effect that hyaluronidase is a valuable adjunct in the treatment of infertility. Dr. Chang and Dr. Werthessen attributed Dr. Kurzrock's success to his excellent timing in determining the date of ovulation.

The conference closed on the note that the spreading substances and ground-plasm are of great significance. Much remains to be ascertained; and a uniform system of units should be devised.

E. D. GOLDSMITH

SCIENCE MASTERS' ASSOCIATION

ANNUAL MEETING

THE forty-sixth annual meeting of the Science Masters' Association was held during January 4–7 in London, at the Royal College of Science. Prof. F. R. Winton, University College, London, in the presidential address on "Specialization", suggested reasons for the undue specialization of school science, contending that boys are driven by a sense of insecurity into scientific studies in their search for truth, but in these studies they seldom meet with experience in the selection and recognition of the vital factors in a problem; and, further, one of the most important approaches, the statistical method, is neglected. Turning to a more detailed consideration of biology teaching, Prof. Winton criticized its subject-matter as being too often narrow and unrelated to human experience; he made a plea for more experimental work in human physiology, and proposed that reform might be brought about through a review of school courses by joint action of the Science Masters' Association and the Biological Council, with medical and psychological representatives.

On the subject of "Phase Contrast Microscopy and the Study of the Living Cell", Dr. Arthur Hughes, after an admirably simple account of the underlying principles, explained how this new technique has made possible the direct study of living cells in tissue cultures. Remarkable results, such as the identification of chromosomes in the resting stage and the formation of tetraploid nuclei, were illustrated by Dr. Hughes' own film of cell division in the spleen cells of the mouse.

In a lecture on "Why Schools should use M.K.S. Electrical Units", Prof. G. H. Rawcliffe pointed out that there is no justification for the present complexity of electrical units. This complexity arose because those who first suggested the units did not realize that the systems involved the permeability and the permittivity of air in addition to the centimetre, gram and second. The simplest unified system is the Metre–Kilogram–Second system, which erects the volt, the ampere and the units dependent on them into an absolute system; this has the advantage of being the system that electrical engineers use, and prevents the confusion between B and H in magnetism and that between D and E in electrostatics.

Sir Charles Goodeve discussed the "Making of Iron and Steel". He referred to the huge amounts of ironstone, coke, limestone and other raw materials used yearly for this purpose, and the selection and control of these by scientific methods. But the human intake which parallels this often lacks preparation, not only in knowledge of the elementary principles of the industry, but also in knowledge of the extremely wide range of trades, crafts and skills that the industry needs to keep it in operation.

The lecture on "The Perception of Light and Colour", by Dr. W. D. Wright, was illustrated by a wealth of demonstrations. Simple experiments were described in which the sensitivity of the eye to light could be compared under various conditions, and the phenomena used, if required, to introduce the idea both of the adaptation of the organism to its environment in biology and the quantum nature of light in physics, as well as the practical problems of vision involved in night flying, driving at night, etc. A method of approach was suggested by which instruction about colour by the art master might be co-ordinated with that by the science master.

Prof. E. D. Hughes, of University College, London, introduced his lecture on "Recent Theories of Organic Chemistry" with a general survey of the application of modern valency theory to problems relating to the structure and reactions of typical groups of organic compounds. Ideas on partial ionic character and resonance hybrids provided explanations of apparently contradictory results of hydrolysis of esters and the reactions of carbonyl and carboxylic groups.

Dr. B. Wheeler Robinson, superintendent of the Physics Division of the National Physical Laboratory, in dealing with "Physics at the N.P.L.", explained how this Laboratory has responsibility for the maintenance of physical standards, for special tests and investigations for the benefit of industry, and for original research arising therefrom. The Physics Division, one of ten divisions which comprise the Laboratory, deals mainly with radiology, heat measurements and acoustics. The measurement of the temperature of molten steel and the thermal conductivity of a building panel were described in more detail, and Dr. Robinson showed how the methods in practice differ from the text-book accounts of them.

"English in the Science Course" formed the subject of a lecture by Dr. D. C. Collins. He pointed out that style is not extraneous ornament; it comes from clear thinking. Words are important to the scientific man as a means by which he explains to 'everyman' the scientific picture of the material world. The difficulty of using words, which is a modern phenomenon, is perhaps due to the decay of the study of the classics, which, *inter alia*, gave a training in the writing of English, and modern courses in English have not completely taken the place of the study of the classics. Dr. Collins suggested possible ways of remedying the deficiency and developing the required skill of writing.

Dr. E. A. R. Ennion described various methods in use at Flatford Mill Field Centre, where he is warden, for the training of students in field-work of all kinds (natural history, geography, local history and rural surveys) and for the initiation and promotion of amateur research. Student groups covered comprise teachers themselves, training college and fifth or sixth form school classes coming with or without teachers and either individually or as corporate parties. The basic assumption was that there is a place for properly conducted amateur research. It is quite feasible for students to acquire the necessary competence provided they are intelligently taught to observe and investigate rather than to listen and collect.

Other meetings included a lecture demonstration by the Gramophone Company on "Sound Recording and Reproduction"; different types of recording apparatus were dealt with and some of the difficulties met with were discussed. A discussion on "The Social Sciences in the Grammar School" was opened by Mr. K. G. Collier, of Lancing College. Points covered were the social sciences as the science of human nature and human society; the emergence of a synthesis of views in this field; the potential educational value of the social sciences for integrating the sixth form curriculum, showing the nature and potentialities of scientific method to arts students and conveying to science students the special adaptation and limitations of scientific method in the human sphere.

The exhibitions of apparatus and books attracted much attention, and the members' exhibition revealed once again this year the considerable thought and ingenuity which are being brought to bear on the teaching of science in secondary schools in Great Britain. The apparatus due to Mr. F. A. Meier (Institute of Education, University of London) formed the major contribution—more than forty items, ranging over many branches of physics; some, like the apparatus for making spiral springs, appealed on account of usefulness; others, like the home-made biprism and Fresnel mirrors, were remarkable for their simplicity; but all reflected the genius of their author.

DEFINITION OF THE PLIOCENE–PLEISTOCENE BOUNDARY

THE question of defining the Pliocene – Pleistocene boundary has become important in recent years, because the practices of different geologists have varied to such an extent that deposits described in one publication as Lower Pleistocene may, in fact, be of the same age as deposits elsewhere called Upper Pliocene. A similar problem is presented to geologists and palæontologists at the boundaries of other geological systems; but the problem of where best to draw a boundary between Pliocene and Pleistocene is one which concerns also prehistorians and anthropologists.

At the eighteenth session of the International Geological Congress, one section devoted itself to the discussion of this topic. Opinions of geologists, palæontologists and prehistorians from many different countries were expressed, and there appeared to be a wider measure of general agreement than had been expected. While these discussions were taking place, the Council of the Congress appointed a temporary commission to advise on the question. The following served as members of the Commission: Prof. Kirk Bryan (United States), Prof. G. Dubois (France), Dr. A. T. Hopwood (Great Britain), Prof. W. B. R. King (Great Britain), Dr. L. S. B. Leakey (Kenya), Prof. C. I. Migliorini (Italy), Dr. K. Milthers (Denmark), Dr. Hallam L. Movius, jun. (United States), Dr. K. P. Oakley (Great Britain), Dr. L. L. Ray (United States), Prof. I. M. van der Vlerk (Netherlands), Dr. D. N. Wadia (India), Prof. D. M. S. Watson (Great Britain), Mr. E. J. Wayland (Bechuanaland), Prof. F. E. Zeuner (Great Britain).

At the conclusion of the meetings, the Council of the Congress accepted the recommendations of the Commission, which were as follows:

(1) The Commission considers that it is necessary to select a type-area where the Pliocene – Pleistocene (Tertiary – Quaternary) boundary can be drawn in accordance with stratigraphical principles.

(2) The Commission considers that the Pliocene – Pleistocene boundary should be based on changes in marine faunas, since this is the classic method of grouping fossiliferous strata. The classic area of marine sedimentation in Italy is regarded as the area where this principle can be implemented best. It is here, too, that terrestrial [Continental] equivalents of the marine faunas under consideration can be determined.

(3) The Commission recommends that, in order to eliminate existing ambiguities, the Lower Pleistocene should include as its basal member in the type-area the Calabrian formation (marine) together with its terrestrial [Continental] equivalent, the Villafranchian.

(4) The Commission notes that, according to evidence given, this usage would place the boundary at the horizon of the first indications of climatic deterioration in the Italian Neogene succession.

From the papers read in the section of the Congress devoted to this topic, which are being summarized in the *Geological Magazine*, it is clear that this definition has wide application.

The following table indicates what we consider to be its implications in parts of Europe.

	Italy		Netherlands*		East Anglia*	Human culture
			continental	*marine*		
Lower Pleistocene	Sicilian (*sensu stricto*)		Lower Brabantian Tiglian	Icenian	Wey-bourne Crag Norwich Crag	Abbevillian
Lower Pleistocene	Villafranchian	Calabrian I, II	Pretiglian	Amstelian	Upper part of Red Crag (Butleyan)	Pre-Abbevillian ?
Pliocene	Upper-most part of Astian		Reuverian	Poederlian	Middle part of Red Crag (New-bournian)	

* Based on a paper submitted by Prof. I. M. van der Vlerk (Netherlands).

This table is based on studies of the faunas of shallow-water marine deposits, and of their continental equivalents where known. The Villafranchian is characterized by a fauna which includes *Elephas, Equus* and advanced bovines. This fauna is widespread and has been used for correlating deposits of the same age in different continents. Thus, the apparent equivalents of the Villafranchian are as follows: in Africa, the Kageran beds (with Pre-Abbevillian pebble-tools); in India, the Pinjor stage of the Upper Siwaliks; in China, the Nihowan stage; in Java, the Djetis beds; and in the Central Plains of North America, the Blanco beds.

While it is evident that the Calabrian stage corresponds with the onset of cool conditions in the type-area, correlation with the glacial sequence in the Alps is not yet agreed. Thus, Dr. R. Selli and Dr. G. Ruggieri, in their paper submitted to the Congress, on the Plio-Pleistocene stratigraphy in Emilia (northern Italy), claim that the Calabrian stages I and II are probable equivalents of the Günz and Günz–Mindel stages of the Alpine sequence, and that the Sicilian (*sensu stricto*) corresponds with the Mindel glaciation. On the other hand, a more widely held view is that the drop from the Sicilian high sea-level was brought about by the first major glaciation (Günz). On this latter reading of the data, the basal or Villafranchian division of the Lower Pleistocene is in large part older than the first important growth of ice-caps, and corresponds with the climatic deterioration which was marked in the Alps, for example, by the Donau phases of glacier-growth. Judging from the great thickness of deposits accumulated during the Villafranchian stage, it was of considerable duration.

K. P. Oakley

LOCUST BEHAVIOUR AND AIRCRAFT SPRAYING

AERIAL spraying has for long seemed to offer the only means of attacking swarms of winged locusts, and an article in *Nature* of March 6, 1948, outlined the history of the latest attempt to develop this method. "We set out", wrote Dr. D. L. Gunn in that article, "systematically to find whether aircraft methods are applicable to locust destruction and to work out where and when they may compete in effectiveness and in cost with other methods"—something that had not been done before. The full story of the attempt is now appearing; the two present publications*† show how formidable the task was and indicate the very remarkable level of team-work achieved among the entomologists, physicists, chemists, meteorologists and airmen who were involved.

The object of the behaviour studies on the desert locust in Kenya* was to discover what governed the time a swarm remained on its roosting site before flying away in the morning, since it was against roosting swarms that spraying operations were then contemplated. Swarms were watched on seventeen mornings, with simultaneous intensive recording of air temperature, humidity, locust body-temperature, radiation and wind. The start of 'stream-away', when the locusts moved off *en masse*, was usually quite sudden. Among all the factors measured, only the air temperature showed some consistency at this time on different days (*Nature*, **156**, 628; 1945). Apart from its possible practical value, this finding raises interesting physiological and behavioural questions, which are discussed. In seeking for an explanation for the variations in the air temperature at stream-away, a correlation was found between that temperature and the previous day's maximum temperature. The latter is regarded as a measure of the general temperature conditioning to which the insects had been exposed, and it is suggested that a form of physiological temperature adaptation may be involved.

The authors succeeded in tracing the roost-to-roost displacements of a single swarm for eighteen consecutive days. The swarm showed an over-all trend northwards, but zig-zagged a good deal. The displacements of a second swarm were roughly consistent with its being carried by the wind. This type of information on insect migration is very rare, and does not support the idea that migrants drive on undeviatingly towards a hypothetical goal.

The spraying trials against roosting red locusts in Tanganyika† demonstrated the inferiority, for this purpose, of the traditional method of trying to fly low enough during spraying to minimize the spray-drifting action of the wind, as compared with the method, new to insecticide work, of flying at a height calculated to use the existing wind to give the desired spray pattern on the ground. 20 per cent dinitro-*ortho*-cresol (DNOC) solution in oil proved so effective, with complete mortality at about one gallon per acre, that it was used in an intensive series of practical operations, 3,700 gallons being sprayed on a total of 3,335 acres. The authors are cautious; but it appears that their operations may well have averted a serious outbreak of the red locust.

By unexpected good fortune, the swarms were virtually stationary during the campaign. The work would have been very much more difficult had they migrated every day. After giving some estimates of costs, the authors suggest that roosting swarms might be tackled more economically with ground machinery, but that aircraft might be more efficient against flying swarms than against roosting ones.

Both publications contain a mass of factual material on subjects which have had little such foundation hitherto, including detailed estimates of locust numbers and densities made by photographic and other methods.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, January 31

Institution of the Rubber Industry, Leicester Section (at the College of Art and Technology, Leicester), at 7 p.m.—Dr. C. M. Blow: "Latex".

Institution of Electrical Engineers, Cambridge Radio Group (joint meeting with the Cambridge University Wireless Society, at the Cavendish Laboratory, Cambridge), at 8.15 p.m.—Mr. L. A. Moxon: "Noise and Band Width".

Tuesday, February 1

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. R. Ogilvie Buchanan: "Some Geographical Aspects of the Economic Development of New Zealand".* (Further Lecture on February 8.)

University of London (in the Department of Civil, Mechanical and Chemical Engineering, King's College, Strand, London, W.C.2), at 5.30 p.m.—Mr. A. H. Willis: "The Mechanical Properties of Matter".* (Further Lecture on February 8.)

Wednesday, February 2

University of London (at Bedford College for Women, Regent's Park, London, N.W.1), at 5.15 p.m.—Sir George Stapledon, F.R.S.: "The Ecology of Food Production".*

University of London (in the Senate House, Malet Street, London, W.C.1), at 5.30 p.m.—Sir John Cockcroft, F.R.S.: "The Application of Atomic Piles in Nuclear Physics".* (Further Lectures on February 9 and February 16.)

Royal Microscopical Society, Biological Section (in the Hastings Hall, B.M.A. House, Tavistock Square, London, W.C.1), at 6 p.m.—Mr. O. D. Standen: "Some Biological Aspects of Experimental Schistosomiasis".

Manchester Metallurgical Society (joint meeting with the Iron and Steel Institute, at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Mr. J. Glen: "Precipitation Hardening Effects in Relation to High Temperature Testing".

Society of Chemical Industry, Food Group (joint meeting with the Portsmouth and District Chemical Society, in the Portsmouth Municipal College, Portsmouth), at 7 p.m.—Dr. L. H. Lampitt: "Food Science in Evolution".

Society of Public Analysts and other Analytical Chemists (at the Royal Society of Tropical Medicine and Hygiene, Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Scientific Papers.

Thursday, February 3

Royal Society of Arts, India, Pakistan and Burma Section (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. W. A. M. Walker: "The Growth of the Jute Industry in India and Pakistan".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Institution of Electrical Engineers, Supply Section (joint meeting with the Institution of Civil Engineers, at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. H. Headland: "Tidal Power and the Severn Barrage". (To be repeated on Monday, February 7, at the James Watt Memorial Institute, Great Charles Street, Birmingham, at 6 p.m.; on Monday, February 14, at the Neville Hall, Westgate Road, Newcastle-upon-Tyne, at 6.15 p.m.; on Monday, March 7, at the Liverpool Royal Institution, Colquitt Street, Liverpool, at 6.30 p.m.; on Wednesday, May 4, at the Harris Institute, Preston, at 6.45 p.m.; and on Wednesday, May 18, at the Wedgwood Café, Albert Road, Bournemouth, at 6.30 p.m.)

University of London (in the Architecture Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Mr. J. R. N. Stone: "The Role of Measurement in Economics" (Newmarch Lectures).* (Further Lectures on February 10, February 17 and February 24.)

Institution of Civil Engineers, North-Western Association (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Mr. W. E. De Courcy Hamilton: "Economic Survey as applied to Civil Engineering".

British Institution of Radio Engineers, North-Western Section (in the Reynolds Hall, College of Technology, Manchester), at 6.45 p.m.—Messrs. A. Levin, Harley and Davidson: "The Design Characteristics of Marine Radar Equipment".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.15 p.m.—Mr. R. P. Bell, F.R.S.: Johannes Nicholas Bronsted Memorial Lecture.

Textile Institute (at 16 St. Mary's Parsonage, Manchester), at 7.15 p.m.—Mr. W. Harrison and Mr. H. Hewitt: "Artificial Daylight—a new Colour Matching Unit".

Friday, February 4

Institution of Chemical Engineers, North-Western Branch (at the Town Hall, Manchester), at 2.15 p.m.—Annual General Meeting; Dr. F. A. Freeth, F.R.S.: "The Place of Heterogeneous Equilibrium in Chemical Engineering".

Physical Society (in the Physics Department, University College, Gower Street, London, W.C.1), at 5 p.m.—Scientific Papers.

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Sir Edward Salisbury, F.R.S.: "Leaves".

Saturday, February 5

British Glaciological Society (in the Department of Geography, Cambridge), at 8.15 p.m.—Dr. H. Godwin, F.R.S.: "Pollen Analysis of Glaciers in special relation to the Formation of Various Types of Glacier Bands".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Lecturer in Physics—The Principal, Acton Technical College, High Street, Acton, London, W.3 (February 5).

Research Organiser in Education, and an Organiser of Teachers' Library and Information Service—The Registrar, University College, Leicester (February 5).

Assistant in the Medical Department to be Sub-Editor of the *British Medical Bulletin*—The Director, Personnel Department, British Council, 3 Hanover Street, London, W.1 (February 5).

Lecturer in Mechanical Engineering, and a Lecturer in Mathematics—The Principal, Heriot-Watt College, Edinburgh (February 8).

Principal Scientific Officer to lead a team developing specialized techniques for investigating the physical and mechanical properties of irradiated and non-irradiated metals and alloys, a Principal Scientific Officer to lead a team developing laboratory-scale fabrication techniques and in testing methods applicable to rare metals, a Principal Scientific Officer or Senior Scientific Officer for work on general metallurgical problems of piles, a Principal Scientific Officer or Senior Scientific Officer for powder metallurgy, a Senior Scientific Officer to lead a team developing radioactive tracer techniques applicable to metallurgical problems, a Senior Scientific Officer to lead a team developing techniques for fabrication of rare metals, a Senior Scientific Officer to lead a team developing and adapting techniques for the physical and mechanical testing of rare metals, a Senior Experimental Officer or Experimental Officer to take charge of metallographic section, and an Experimental Officer for metallographic section, at the Atomic Energy Research Establishment, Harwell—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2394 (February 8).

Mechanical and Electrical Engineer in the Prison Commission—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2371 (February 10).

Economic Mining Geologist to make a survey of the known mineral resources of Burma, Geologists for the Geological Department, and an Economic Statistician to take charge of the Statistical Department under the National Planning Board—The First Secretary, Burmese Embassy, 19a Charles Street, London, W.1 (February 11).

Post-graduate Research Studentship in Veterinary Parasitology, and a Research Assistant in the Department of Zoology—The Registrar, The University, Liverpool (February 12).

Lecturer in the Department of Chemical Pathology—The Professor of Chemical Pathology, King's College Hospital, Denmark Hill, London, S.E.5 (February 12).

District (Forest) Officers—The Secretary, Forestry Commission, 25 Savile Row, London, W.1 (February 15).

Assistant Lecturer in Chemistry—The Registrar, University College, Singleton Park, Swansea (February 24).

Lecturer (ungraded) in Farm Animal Medicine, a Lecturer (ungraded) in Veterinary Physiology, a Lecturer (ungraded) in Veterinary Biochemistry, and an Assistant Lecturer (Grade III) in Veterinary Anatomy—The Registrar, The University, Liverpool (February 28).

Biochemist and a Physical Chemist for the Atlantic Fisheries Experimental Station, Halifax, Nova Scotia—The Executive Director, Fisheries Research Board of Canada, Department of Fisheries, Ottawa, Canada (March 1).

Lecturer in Physics in the University College of the West Indies—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (March 1).

Readership in Taxonomy in the Department of Botany at University College—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 2).

Head of the Department of African Studies in the University College of the Gold Coast—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (March 19).

I.C.I. Research Fellowships in Biochemistry, Chemistry, Engineering, Pharmacology, Physics or allied subjects—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Forest Mensuration Officer, Silviculturists (one for northern temperate softwoods silviculture, one for genetics research in northern temperate softwoods, and one for indigenous forest ecology and silviculture), a Forest Entomologist, a Timber Technologist specializing in kiln and chemical seasoning, and a Timber Technologist specializing in plywood and laminated construction, in the N.Z. State Forest Service—The Office of the High Commissioner for New Zealand, 415 Strand, London, W.C.2 (April 30).

Turner and Newall Research Fellowship in Engineering, Inorganic Chemistry, Physics or an allied subject—The Academic Registrar, University of London, Senate House, London, W.C.1 (April 30).

Senior Lecturer (Grade I) in the Department of Physics—The Registrar, The University, Liverpool (May 1).

Research Chemists to engage in research on coal tar at the Research Station, Gomersal, Yorkshire—The Director of Research, Coal Tar Research Association, 9 Harley Street, London, W.1.

Technician (Grade III), having a pathological background, in the Department of Genetics—The Secretary, University College, Gower Street, London, W.C.1, quoting 'Genetics/1'.

Botanist (Plant Breeder) in the Department of Agriculture, Nyasaland—The Director of Recruitment, Colonial Service, Colonial Office, Great Smith Street, London, S.W.1.

Technical Assistant (male or female) at the Medical Research Council's Radiobiological Research Unit, Harwell—The Director, Radiobiological Research Unit, Atomic Energy Research Establishment, Harwell, Didcot, Berks.

Research Engineer or Physicist to carry out investigations on mechanical and electrical problems connected with the dyeing and finishing of textiles—The Research Manager, British Cotton and Wool Dyers' Association, 351 Lower Broughton Road, Salford 3.

Technician (Grade B), with histological experience, in the Department of Surgery—The Secretary, Marischal College, Aberdeen.

Mineralogical Chemist in the Geological Division of the Lands and Mines Department, Tanganyika—The Director of Recruitment (Colonial Service), Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Laboratory Technician as biochemical research technician in the Department of Dental Medicine—Prof. M. A. Rushton, Guy's Hospital Dental School, London Bridge, London, S.E.1.

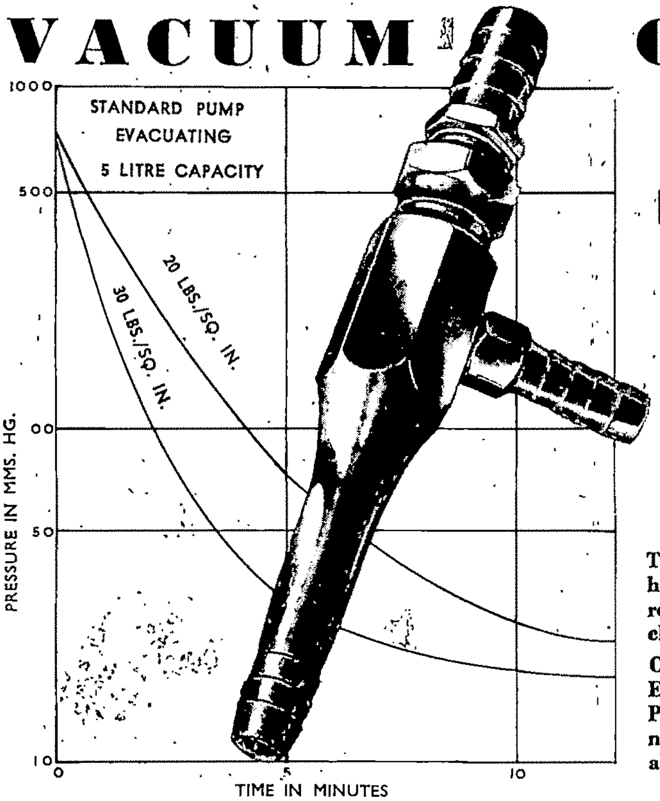
Assistant Professor who is an honours graduate in Mechanical Engineering, and Lecturers (2) with honours degree in Mathematics at the Royal Naval College, Greenwich—The Secretary, Admiralty (C.E. Branch 1), London, S.W.1.

Research Technician for histological work and other duties—The Director, Department of Surgery, Guy's Hospital, London Bridge London, S.E.1.

Administrative Director of the Department of Technology, and an Administrative Assistant—The Secretary, City and Guilds of London Institute, Gresham College, Basinghall Street, London, E.C.2.

Laboratory Technicians (one Senior and one Junior)—The Secretary, Northallerton Hospital Management Committee, Friarage Hospital, Northallerton, Yorks.

VACUUM ON TAP!



EDWARDS
METAL WATER JET PUMPS

- FILTRATIONS
- AERATIONS
- DISTILLATIONS
- SURGICAL WORK

The Filter Pump is a commonplace piece of equipment, hence although efficiency and reliability are the chief requirements, very little consideration is given to these characteristics when purchasing.

Considerable care and research have been devoted to the Edwards series, because in our opinion the Water Jet Pump is an essential unit of vacuum equipment. The new jet combines improved pumping performances and ability to work against low water pressures.

HUMAN RIGHTS AND PEACE

DURING the first autumn of the Second World War a Declaration of Human Rights was drafted by Mr. H. G. Wells, who suggested that it should be adopted as a statement of Allied aims and an expression of the spirit in which we face life in general. More than nine years later the essence of the ten clauses proposed by Mr. Wells has found expression in the thirty articles of the Charter of Human Rights adopted by the General Assembly of the United Nations in Paris on December 10. Much that has happened in the interval has engendered a certain scepticism as to the value of what can equally be described as a Declaration of Peace Aims. The long debates and discussions of the past two and a half years which have issued in the Charter seem at times to encourage the view that it is essentially a manifesto of ideological warfare expressing the ideals and beliefs of Western civilization.

Any such cynicism should be checked by the realization that no government in existence, even in the Western world, is able to guarantee to all its citizens all the rights laid down. These rights are proclaimed for everyone without distinction of any kind, and the Declaration is clearly meant to apply equally to those who are furthest from attaining them. Only the last two articles, with their emphasis on duties and responsibilities, in any way limit those rights. "Everyone has duties to the community in which alone the free and full development of his personality is possible"; and the only limitations on the exercise of human rights and freedoms are declared to be such as are determined by law "solely for the purpose of securing due recognition and respect for the rights and freedoms of others and of meeting the just requirements of morality, public order and the general welfare in a democratic society".

Safeguarding the State may obviously be made an excuse; but the exercise of State interference in accordance with elastic interpretations of democracy is limited by the final article: "Nothing in this Declaration may be interpreted as implying for any State, group or person any right to engage in any activity or to perform any act aimed at the destruction of any of the rights and freedoms set forth herein". Moreover, the inclusion of such reservations in a separate general article does not detract from the strength of the rest so much as would a succession of reservations to the individual articles. It is also worth noting that there has been a surprising degree of unanimity in adopting the successive provisions, and that this provision of a common standard of achievement is to lead to a later international covenant which will be even more binding.

Certain of the articles are vague, and the differing interpretations of such words as 'freedom', 'impartial', or 'protection' is bound to introduce some uncertainty, particularly in the economic field, at least until some such common tradition as lies at the basis of Western Union becomes of world-wide validity. Nevertheless, many of the articles can scarcely be misunderstood, and they supply strong support for the individual or the professional association in any demands for fulfilment they may have to make upon the State. There was, indeed, strong resistance from the Communist bloc to the inclusion of the right to freedom of movement and residence within the borders of each State, of the right of a person to leave his own or any other country and to return, to freedom of thought, conscience and religion, and the sharing of the common cultural life ; but the majority of the United Nations declared firmly for the provision of universality at the start of the Declaration and the sufficiency of the reservations at the end.

Clearly the Declaration embodies the principles which men of science have long held to be essential for the full vigour of a fruitful scientific and creative life, and the debates from which the Declaration has emerged can leave them in no doubt as to where the real dangers to scientific activity lie to-day. The Declaration obviously calls for close consideration from the Committee on Science and its Social Relations, and from the General Assembly of the International Council of Scientific Unions, in view of the resolution adopted by the latter Assembly in July 1946 and a subsequent declaration on the principles of a charter for scientific men since adopted by the Committee. It equally deserves consideration by that growing body of scientific workers concerned with ways in which science could help towards the maintenance of peace.

A comprehensive report on science and the maintenance of peace has been prepared for the Committee on Science and its Social Relations, but an interim report was issued by B. J. Bok, chairman of the U.S. National Research Council Committee of the United Nations Educational, Scientific and Cultural Organisation, for use at the Boston meeting of the United States National Commission on the latter body in September 1948. In that report, Mr. Bok attempted an analysis of the twenty-two replies received to two questions addressed during the summer to some forty representative scientific workers. Replies to the first question, dealing with the measure in which the methods of international scientific work contribute to the creation of an international spirit and to the maintenance of peace, almost all stress the international character of science. Many clearly feel strongly that, because of the special nature of their work, they are in a favoured position with regard to international collaboration, though some believe that scientific contact alone has comparatively little to do with securing peace.

Much stress was laid in the replies to this question on the effectiveness of international exchanges of scientific workers at all levels, and on the value of international exchanges of scientific literature and advances in scientific abstracting. Moreover, the replies recognize the importance in this connexion of several projects undertaken by the Natural Sciences Department of the United Nations Educational, Scientific and Cultural Organisation, such as the establishment of the Field Science Co-operation Offices, the Hylean–Amazon Institute and the work on scientific reconstruction. One reply emphasized that the method of science assists men to put aside the conventional reactions and prejudices that hinder our understanding of unfamiliar things ; and that the evolutionary character of scientific theories helps to provide the flexibility of mind necessary for the maintenance of peace in a world so varied and diverse. The principle of freedom of inquiry, it is claimed, is a great asset in the maintenance of world peace because it is hard to reconcile with doctrinaire politics and dogmatic adherence to particular social or political theories. Whether or not this belief is too optimistic—and it was strongly attacked by implication by Dr. A. P. Lehner in his comments in the *Bulletin of the Atomic Scientists' Association* on a suggestion that scientific men and engineers should refuse to participate in weapons research and development—this view indicates sufficiently why the man of science cannot wisely neglect to support the Declaration of Human Rights, or to follow with interest the activities of the United Nations Educational, Scientific and Cultural Organisation.

The replies received to the second question, referring to the ways in which scientific organisations and individuals could intensify their activities for the maintenance of peace, yielded a number of suggestions with which the activities of Unesco are wholly in line, notably those in connexion with the forthcoming Scientific Conference on the Conservation and Utilization of Resources. Strong support was forthcoming for continuing the work of the international scientific unions and for increasing personal contacts among scientific men all over the world.

Nevertheless, the prevailing opinion seems to have been that it is a matter of hope rather than of history that the increasing knowledge of the world, improved communications and transport of goods and raised standards of living can minimize the causes of war by reducing stimuli to aggression. Prof. H. C. Urey sees the establishment of world government as our ultimate aim, but despite the general agreement that science fosters peace rather than war, Dr. K. T. Compton is supported in his view that the responsibilities for peace of scientific workers are just the same as those of any other group of citizens. He does not believe that it is feasible or, in the long run, safe for men of science to attempt to exert their own controls on the products of their work; and in this view Dr. H. N. Russell concurs, pointing out that the maintenance of peace is so entangled with sincere differences of social and political belief that it would be unwise for scientific organisations, as such, to endorse any particular programme. Dr. Lehner develops this point more particularly in his article in the *Bulletin of the Atomic Scientists' Association* already noted, and shows the difficulties to which the assumption by men of science of special responsibilities in this way would lead. There is no solution, he urges, in giving power to leaders of science, for they, too, are men ; and the economist comes firmly down on the same side, urging that the most those who want peace can do is to try to guide their fellow men by participation in political action for the world government that is necessary for peace.

At the meeting at Boston on September 28 when this interim report was discussed, Dr. A. H. Compton suggested that there are four ways in which it is appropriate for the United Nations Educational, Scientific and Cultural Organisation to use science towards the maintenance of peace. The first is by emphasis on human values; science and technology should be considered as means for attaining these values. The second is insistence on freedom and honesty in our search for knowledge. Next comes the development of science on a world-wide front, giving the opportunity for scientific men themselves to become the prototypes of the world citizen and thus to provide for all nations natural channels of human intercourse with their neighbours. Finally, there is the encouragement of the growth of science and technology throughout the world. Dr. Compton appears to regard this last as the most powerful existing force working towards world peace.

These suggestions were generally approved at that meeting, and a resolution adopted for forwarding to the United States National Commission urged that scientific men should work for the maintenance of peace in four ways: (*a*) They can emphasize and develop the human values associated with science and technology, and (*b*) insist on freedom in their search for knowledge. (*c*) Because of the natural one-worldness of their fields, they can consciously serve as prototypes of world citizens, and (*d*) by systematically promoting international co-operation, they can contribute directly to world integration and the construction of the defences of peace.

The subsequent report of the Committee of Science and its Social Relations issued in November 1948 gives an analysis of some seventy replies to the two questions, but its trend is sufficiently well shown by Bok's interim report, although some of the individual opinions quoted in the final report deserve attention. Generally, the replies to the first question testify to the existence of an international spirit among men of science, and regard its existence as favourable to the development of other aspects of international co-operation, in particular that of union, because men devoted to honesty, objectivity and freedom of scientific investigation, whatever their nationality, influence favourably other fields of human relations. Although one group of replies to the first question considers that men of science can exert a direct influence on the political world, either by appropriate public declarations or by the formulation of moral or ethical codes of conduct, the great majority see the most favourable possibilities of action in their normal activities. All correspondents, however, were unanimous in insisting on the necessity of intensifying their support of the projects for co-operation initiated by the United Nations Educational, Scientific and Cultural Organisation and by the international unions. Indeed, the whole inquiry brings out once more the independence of the scientific attitude, and the general belief among men of science that the fundamental contribution of science to world peace lies in the support it gives to freedom of thought, investigation and publication and the free circulation both of ideas and of men.

Little fresh has thus come out of the inquiry, and it may well be urged that the value of scientific work in creating an international spirit and encouraging the movement of thought across national frontiers needed no such demonstration. Nevertheless, some of the replies are valuable as indicating the dangers that lurk in proposals for direct political action by men of science as such. Perhaps more important is the demonstration of the existence of a substantial body of opinion which is following the activities of the United Nations Educational, Scientific and Cultural Organisation with interest and is capable of the cogent and constructive criticism of its activities which the Organisation needs. It is unfortunate, whatever the cause, that so little interest is taken in those activities in Great Britain. Parliament is obviously not interested, and there is no indication whether the universities, the professional organisations, the Churches and those practical people engaged in education, science and cultural activities generally are satisfied that the right projects are being attempted in the right way. A vigorous defence of the general purpose and policy of the Organisation was, it is true, offered by Mr. Ronald Gould at the recent conference on higher education held by the National Union of Teachers in London. Mr. Gould was careful to distinguish between criticism of administration, which might be merited, and destructive criticism of objectives.

However sound the fundamental conception of the United Nations Educational, Scientific and Cultural Organisation, that purpose of fostering co-operation and understanding among all peoples will only be achieved through the free flow of thought and expression throughout the world. The close support and keen interest of scientific workers is as essential a factor here as their support, interest and criticism are for the formulation of practical projects by which international co-operation and understanding can be furthered. The general indifference to the proceedings of the Organisation's recent meeting at Beirut is the more disappointing, for there was evidence that an attempt is being made to rectify past mistakes. Plain speaking is still required, and the most hopeful feature of the inquiry set on foot by the Committee on Science and its Social Relations is that it shows there are responsible men of science in the International Council of Scientific Unions who recognize the potentialities of Unesco, and whose standing ensures a hearing for any criticism they may have cause to make of its programme or administration. If such criticism is to be fully effective and this means of using science for furthering the maintenance of peace is to succeed, there must be public as well as scientific scrutiny; and one duty which scientific workers as citizens should undertake is to see that the projects of such an international body are rigorously scrutinized, the good approved and supported, and the weak exposed firmly but constructively as the obstacles they are in truth to the cause of international understanding.

THE COMPLETE CORRESPONDENCE OF LEEUWENHOEK

The Collected Letters of Antoni van Leeuwenhoek
Edited, illustrated and annotated by a Committee of Dutch Scientists. Vol. 3: 1679–1682. Pp. viii+565+48 plates. (Amsterdam: Swets and Zeitlinger, Ltd., 1948.) n.p.

THE third volume of this stupendous work includes letters 43–69 (old enumeration 28–36), and covers the period April 1679–July 1682. Seven of the letters, however, are those which have either not been recovered or have no scientific value, but which are properly catalogued in order to maintain the completeness of the record. It is of interest to note, but withal disappointing, that the new material now brought to light is of no great importance, and hence the letters already wholly or partly published in various quarters have so far not proved to be seriously deficient. Perhaps the most significant point to be established in the present volume is the date when Leeuwenhoek first discovered the nucleus of the animal cell. In the printed Dutch and Latin versions of letter 67 (35) it was doubtful whether he had seen the nucleus of the oval red corpuscles of fishes; but the original drawing now photographically reproduced for the first time shows clearly that he had seen the nucleus of the fish red corpuscle in March 1682. His next reference to the nucleus, this time in squamous epithelium, was in 1686. The etched figures in the Dutch and Latin "Opera" do not show the nucleus.

Among the diverse researches which Leeuwenhoek describes in these few letters are the following: spermatozoa of man and various animals, and how their number is estimated; the question whether spermatozoa and animalcula are complete miniature organisms with all the parts of larger complex forms; Hooke's demonstration to Charles II of some freshwater Infusoria (*not* spermatozoa); ciliary action of Infusoria and the gills of the oyster, and its uses; first mention of his observation of blood capillaries; viviparous generation in the female vinegar-eel; microscopic structure of the vessels of wood; histology of the testis of rat; discovery of anaerobic bacteria; impossibility of spontaneous generation; mechanism of the circulation of the blood; lacteal vessels of lamb and calf; biology of yeast; generation and anatomical notes on various insects and mites; microscopic structure and growth of hair in man and pig; discovery of the human intestinal flagellate *Giardia*; microscopic structure of striated muscle in vertebrates and invertebrates; nucleated red blood-corpuscles of fishes. On all these matters Leeuwenhoek produces new observations and acute inferences to the enlightenment of astonished readers.

In our previous reviews of this work (*Nature*, 144, 956, and 157, 3) we took occasion seriously to criticize its English translations. In the present volume the English version is very greatly improved and modernized. It is true that now and again the idiom is somewhat un-English, but without unduly affecting the interpretation. Thus a literal translation has not usually a 'literary' value, a gradually darkening border becomes a "slowly shadowing contour", an author "lays his views down" when he publishes them, the labial palps of the oyster appear as the "flaps" of the mouth, the ciliary action of the gills of the oyster "dabbles" the water, Leeuwenhoek's Royal Society diploma with appended seals appears ambiguously as a "sealed" diploma, and so on. These may not be considered serious defects; but they do underline the contention, which we have already twice maintained, that the English translation should be revised by an English biologist. Surely a great and essential work, such as this enterprise undoubtedly is, deserves, if it does not demand, the final polish.

The commentaries on the text supplied by a large group of specialists are especially valuable, but are occasionally unacceptable and more rarely inaccurate. The following points may be mentioned: p. 7, the statement that, according to the Dutch and Latin "Opera", there may be more than "10,000 thousand" animalcules in a space equal to one sand grain of matter does not occur in the Latin versions but only in the Dutch. P. 59, the blood capillaries were not first referred to in the letter of May 20, 1679, but in two letters of February 11, 1675, and May 14, 1677. P. 211, in *Mytilus*, Leeuwenhoek observed the *discrete* nature of the gill filaments and also the ciliary junctions; but he was not aware how they functioned in holding the filaments loosely together. The interpretation of the commentator would suggest that he was not too familiar with the structure of the gills of *Mytilus*. P. 229, line 6, for 1886 read 1686. P. 243, the first Latin edition of letter 62 has been accidentally omitted. P. 259, there are no gastroliths in the crab, which negatives the view that they constitute a reserve of calcareous material for use in the formation of a new shell. For such a purpose they are manifestly inadequate. They may be formed from the lime known to be abstracted from the shell before moulting to ensure that the process is unattended by amputations; but the same objection applies to this interpretation though to a less extent. The gastroliths figured in Plate 34 were obviously taken from the lobster. P. 323, the *big* horse-fly could scarcely be a *Hæmatopota*, and still less a *Stomoxys*. Why not a *Tabanus*? P. 331, the eggs of a gnat, notes Leeuwenhoek, had a *very clear* spot on one *side*. The commentator interprets this as the micropylar process, which does not tally with what Leeuwenhoek says. The clear spots might be the nuclei of the oocytes.

The Letters are followed by a reasoned critique by van Iterson, in which it is claimed that Leeuwenhoek's studies on the structure of wood (magnified seventy times) were largely independent of the contemporary works of Malpighi and Grew, and were in many respects superior to them. Leeuwenhoek is credited with being more restrained and intuitive in his deductions. Van Iterson is followed by Dijksterhuis, who reviews and collates the mathematical terms and micro-metric methods adopted by Leeuwenhoek, and in another place there is a list of the weights and measures employed in the Letters. The 48 plates of the volume introduce such extra figures as are necessary for the interpretation and illustration of Leeuwenhoek's observations and speculations, and, what is more important, we now have photographic reproductions of all Leeuwenhoek's own drawings, which may profitably be compared with the copper plates of the earlier printed editions. The book is completed by a bibliography and biographical notes on the authorities quoted in the text, and there is a good index.

The Leeuwenhoek Commission is to be handsomely complimented on its determination to continue the publication of this great historical work in the sumptuous style of the two volumes printed before the War. In Holland, apparently, questions of space, paper and binding have few terrors for the publisher. Last, but far from least, the large public unfamiliar with the Dutch language will be very grateful for the English translation.

F. J. Cole

THE GLOUCESTERSHIRE FLORA

Flora of Gloucestershire

Phanerogams, Vascular Cryptogams, Charophyta. Edited by the Rev. H. J. Riddelsdell, G. W. Hedley and W. R. Price. Pp. clxxxii+667+44 plates. (Cheltenham: Cotteswold Naturalists' Field Club, 1948.) n.p.

It is remarkable that so important a botanical area as the county of Gloucestershire should have had to await for so long the consummation of an account of its flora. The project was first conceived by the late Prof. Boulger some seventy years ago, and he had by 1878 compiled a list of more than a thousand species from this area. Nevertheless, except in respect of the Bristol region and casual records, very little real progress was again made until the impetus given by the Rev. W. Butt in 1905, and from 1908 to the time of his retirement by the Rev. H. J. Riddelsdell, who compiled what constitutes the main substance of the present work. But, though belated, the outcome is a Flora that is worthy of the botanical wealth which it enshrines.

There are here recorded 1,126 native species, 40 denizens and 23 colonists—a total of 1,189 species of vascular plants that includes such rarities as *Cephalanthera rubra*, the red helleborine, *Ranunculus ophioglossifolius* the adder's-tongue buttercup, and *Trinia glauca*, the honewort. Of all the species here enumerated, sixteen are noted as having become extinct, and of these, as is usual in other counties, the greatest proportion, namely, nine, are damp-habitat plants. Four of the extinct species are seaside plants and one is characteristic of woodlands.

The revision of names in accord with international rules has produced a number of unfamiliar labels for familiar friends, changes which cannot but be deplored when they do not reflect any increase of botanical knowledge. One new species is here described and figured under the name of *Epipactis cleistogama*.

The Flora is planned upon traditional lines, the records being grouped in respect to nine botanical districts. An unusual feature is the provision of keys to some of the groups, such as the Batrachian Ranunculi by Dr. Butcher, the Carices by Mr. Nelmes and the Gramineæ by Mr. Hubbard. The last-named has provided keys not only to the species in each of the genera but also to the genera themselves.

Gloucestershire has for the student of plant distribution an especial interest, since various species are here at or near their geographical limit. The pasque flower (*Anemone pulsatilla*) and *Senecio campestris*, both members of the Continental element in the flora of Britain, attain here their western limit, and this is true also of the Continental orchids, *Orchis ustulata* and *Himantoglossum hircinum*. But the ground pine (*Ajuga chamæpitys*) and the spider orchid (*Ophrys aranifera*) do not extend into the area. The endemic aconite (*Aconitum anglicum*), which is essentially a western plant in England, is here probably at its eastern limit, though, since it is stated that some of the records are probably garden escapes, the doubt arises whether the endemic plant has been adequately distinguished from its cultivated congener. The western *Andromeda polifolia*, on the other hand, has its eastern limit to the west of Gloucestershire. Again, the northern *Prunus padus* here attains its southern limit; but the local *Phyteuma tenerum*, though found in Wiltshire, fails to reach the chalk of Gloucestershire. These few examples suffice to indicate the importance of distribution data for this area and the need for biological studies in respect to such marginal species.

The present work is a notable addition to the county Floras of Britain and a valuable contribution to the literature of geographical distribution of plants in Britain. The text is embellished with views of typical Gloucestershire habitats and portraits of some of the rarer and more interesting species.

ELEMENTARY PHYSICS

A Laboratory Manual of Physics

For Higher Certificate, Scholarship and Intermediate Science Students. By Dr. F. Tyler. Pp. 207. (London: Edward Arnold and Co., 1947.) 7*s*. 6*d*.

Intermediate Physics

By Dr. C. J. Smith. Third edition. Pp. xii + 1033. (London: Edward Arnold and Co., 1947.) 18*s*. net.

Electricity

Text Book and Laboratory Manual for Inter.B.Sc., Higher School Certificate, University Scholarships, etc. By M. M. Das. Pp. xi + 483. (London: T. Murby and Co., Ltd., 1947.) 25*s*. net.

General Physics

By A. E. E. McKenzie. Pp. viii + 499. (Cambridge: At the University Press, 1948.) 8*s*. 6*d*. net.

Dr. F. Tyler's collection of experiments is intended to cover the practical work required for higher school certificate and university scholarships, and also for first-year university courses. Most of the really profitable class experiments which can be done with simple apparatus are included, and this carefully chosen list probably represents the highest common factor of all courses of this standard. Instructions, of the kind usually issued to students as 'manuscripts', explain the operations required, and show how the readings should be set out and the results calculated. The theory of each experiment is given in some detail, and, where the results are to be plotted, notes on the full interpretation of the graph are supplied.

Laboratory manuals can only reveal their quality in class, and it so happens that the reviewer has tried the book for more than a term with a small set of boys who had to work with little direct supervision. The results were satisfactory, and the pupils liked the book, which serves its purpose very well. Criticisms which arose in use are that the problem on the oscillation of a loaded tube on page 15 is more difficult than it appears, since the timing of more than a few oscillations is impossible; the directions for the location of neutral points in experiment 66 are those usually given, but are inadequate (it is suggested that Owen's method might be described in future editions, since this does find a point rather than a somewhat large area); and in the metre-bridge experiment it is surely better to calculate separate values for the resistance, and take the mean, than to average the balance-lengths first. The importance of recording each observation is stressed in the introduction, yet, in some cases, heights which are differences between observations are to be written in the notebook; and, since the accuracy of the observations is supposed to be estimated, some assistance in this might have been given by including a few lines of instruction below the actual observations.

Some small points perhaps deserve reconsideration. It is a half-truth to say that lycopodium sets in small heaps at the nodes in Kundt's tube experiment; the remarks on the cooling-curve experiment of p. 129 are inconsistent with the excellent discussion of Newton's law of cooling on p. 125; the chief purpose of the lid in the method of cooling is to prevent evaporation from the calorimeter; and if the width of the aperture in the Clément and Desormes experiment is considered, this is really a problem on critical damping—it is wrong to imply that oscillations occur with narrow rather than wide tubes when the reverse is the case. Perhaps it would be better also to discuss the damping correction for the ballistic galvanometer before the first experiment in which it is used, since this correction is often quite considerable, and should always be made.

The book is free from serious errors, and the instructions are unmistakably clear. It can be recommended as a valuable laboratory guide which both teachers and pupils should find most useful.

In its third edition, Dr. C. J. Smith's "Intermediate Physics" appears thoroughly revised and to some extent re-written. In the general physics section a short account of the method of dimensions has been added; in the heat chapters a full account is given of methods of determining thermal conductivity, and the chapter on radiation is chiefly new. The work on optical instruments has been considerably extended, and though the laterally expanded diagrams of ray traces at first look a little ungainly, their value is evident when one has become acclimatized to them; this kind of diagram is certainly something to commend to examination candidates. The section on wave-motion and sound is interesting, and does not sacrifice precision in order to economize the student's mathematics; this is, of course, work which is valueless unless it is done thoroughly, and there are no half-measures here. The account of Lissajous figures has been expanded; and the Doppler effect is very neatly done. In the electricity section, new material on dielectric theory and magnetometry has been included, and the chapter on electromagnetic induction revised.

The result is a very satisfying book, which not only includes all the material from which Intermediate examiners select their formal exercises, but also gives abundant guidance on those matters about which the better students themselves often ask such searching and shattering questions. Examples of this are the treatment of the Lees disk experiment for bad conductors, and of that frequent motion for debate, the simple magnifying glass.

Some experiments are described in detail—usually those which require some special care and are more difficult than students expect. Several good demonstration experiments which are old, but not often quoted, make a welcome re-appearance, and there are modern versions (which should work well) of some of the more temperamental of the stock repertoire.

The account of modern physics is necessarily brief. The author modestly says it is "just sufficient to whet the student's appetite for more, but not sufficient to distract him from the more fundamental parts of the subject". It might be said that Dr. Smith's admirable exposition of the fundamentals defies distraction; in any event, the last chapter contains all that one expects Intermediate or first M.B. candidates to know of this work.

The book is intended for scholarship candidates as well as Intermediate students, and what it really does is to cover the topics of the Intermediate syllabus at scholarship level; that is, although one would expect a scholarship boy to have read more widely, he would probably not need to go more deeply into the work that is presented here.

Few errors would be expected in a book which has reached its third edition after fifteen years of class use, and none was found; the words 'chemical' for 'thermal' on p. 204, and 'mainspring' for 'hairspring' on p. 751, are ingenious misprints rather than errors. The production and binding are good, and, for a book of this size and quality, the price is very reasonable.

Mr. M. M. Das's text-book, of Intermediate standard, on electricity deals with the mathematical theory of the magnetic and electric fields side by side in the opening chapters, and then discusses atomic structure before proceeding with the further development of the subject-matter. The treatment of magnetic measurements and magnetic materials is well done, in rather more detail than one usually expects at this stage, and the theoretical calculations throughout the book are clearly explained, particular attention being paid to the question of units. It is intended that the book should serve as a practical manual as well as a text-book, and while many of the experimental instructions are clear and adequate, they strike one as being, on the whole, too brief. There are a number of misleading slips: the theory of the quadrant electrometer is worked out plausibly by equating the *gain* of potential energy of the system to the work done on the fibre; "a new unit of potential, employed in nuclear physics, is the electron-volt"; atomic weight and mass-number are identified; and it is stated that the penetrating power of X-rays is inversely proportional to the wave-length. The price of the book seems unduly high, and would, one imagines, prevent any wide adoption as a class-book. For twenty-five shillings, too, we might have been given the answers to the numerical examples. But the author has thought out his own method of presentation, and teachers in search of ideas will scan the book with interest.

Mr. A. E. E. McKenzie has selected the appropriate material from his well-known series of text-books so as to include in a single volume all the work needed for the rather limited physics syllabus of the school certificate general science paper. The book covers this ground lucidly and well. It embodies all the pleasing features of the earlier ones, and has some new and relevant illustrations, selected with an artist's eye. There was an obvious need for such a book, and Mr. McKenzie has filled it satisfactorily.

G. R. NOAKES

Inductance Calculations

Working Formulas and Tables. By Prof. Frederick W. Grover. Second printing. Pp. xiv+286. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1947.) 31*s*. 6*d*. net.

PROF. F. W. GROVER makes an authoritative selection among the numerous formulæ which have been suggested for the calculation of mutual and self inductances. He does not attempt proofs of the formulæ, but gives adequate references to the original papers. He gives sufficient explanation of general principles to allow the adaptation of the formulæ to particular cases which are not directly covered (an improbable contingency, however). As the majority of exact formulæ are cumbersome to use, he usually offers numerical tables giving an accuracy of 1 in 1,000 or better, with some indication of the accuracy. Where interpolation between tabulated values would be inaccurate, he gives either alternative formulæ or tables using a different argument. Every likely shape and relative disposition of circuit element is included. There are formulæ for deeply wound coils, and for coils of spaced turns of round wire or of flat tape. The discussion of inductance at high frequencies is less precise than the rest of the book—excusably so, in view of the uncertain effects of self-capacitance. (Here is a field for some useful new work.) The mechanical forces between inductors are also calculated.

The most serious criticism is that the detailed contents pages do not atone for the lack of an index. The "Appendix" promised on p. 26 proves, on diligent search, to be Chapter 22 (which is not the last in the book). Most of the tables are admirably set out; but the type is sometimes small, for example, on p. 84, where it is difficult to count the zeros preceding the significant figures. There is a real need for a work of reference of this kind, and the increased scope of this book, as compared with its predecessors, makes it very useful indeed. A. C. LYNCH

Organic Evolution

By Prof. Richard Swann Lull. Revised edition. Pp. xx+744+31 plates. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1947.) 40*s*. net.

ALTHOUGH bravely marked as "Revised Edition" on the title-page, this appears to be no more than a reprint of the revised edition of 1929, which was itself not greatly modernized from the original of 1917. Perhaps it would have been kinder to have allowed this old favourite to go out to grass on the upper shelves of the library. The sections on adaptation to different environments, and the chapters on the evolutionary comparative anatomy of various groups of animals still provide an easily read, if out-of-date, introduction for elementary students. But the sections dealing with the processes of evolution are pathetic. The single short chapter on "Heredity", for example, contains fairly long paragraphs on such pre-genetical ideas as atavism, telegony, prenatal influence and the transmission of parental conditions; and although a sentence is inserted stating that "What is called telegony does not actually exist", the discussion leaves the definite impression that all four ideas are more or less acceptable biological concepts. The following paragraph on sex determination achieves the noteworthy feat of discussing this problem without once mentioning chromosomes; but the discussion on Mendelism, after devoting a total of four pages to an explanation of the F_2 1 : 2 : 1 ratio, does reach out towards the present sufficiently to incorporate a final two lines: "Mendel's laws, therefore, are apparently a generalisation of the greatest importance and apply universally to all cases of inheritance". C. H. W.

Copsford

By Walter J. C. Murray. Pp. 164+23 plates. (London: George Allen and Unwin, Ltd., 1948.) 12*s*. 6*d*. net.

IN many branches of physical science the amateur is inevitably becoming less important; in the observational branches of natural science his place is still as secure as it was in the days of Gilbert White, Jefferies or Hudson; and occasionally someone appears who shows the contribution which the non-professional can still make not only to our knowledge of natural life but also to its significance for the well-being of man.

Such a one is Walter J. C. Murray, whose "Copsford" gives us perhaps one of the most intimate accounts of Nature since Hudson wrote his "Far Away and Long Ago" some thirty years ago. Murray spent a year in a lonely cottage with neither road nor footpath connecting it with human habitation, working among the wild life which surrounded him. There he struggled with the elements, earned a living by harvesting wild herbs and waged continual war against the legion of rats which contested his right to live in Copsford.

He has now written a book about the countryside which is full of the most intimate experiences among the wild life of woodland and meadow, marsh and brook. In his book the author conveys the impression that he not only lived among wild things but also with them, light and darkness, sound, scent and movement becoming as vital in his life as in theirs. This strange, amusing and exciting story is told in prose which in itself is a pleasure to read. "Copsford" deserves the widest possible acquaintance.

T. H. HAWKINS

The Phasian Bird

By Henry Williamson. Pp. 341. (London: Faber and Faber, Ltd., 1948.) 10*s*. 6*d*. net.

IN this latest volume from his pen Mr. Henry Williamson tells of life on a Norfolk farm during the Second World War, taking as his hero a bird, namely, a hybrid pheasant. With the pheasant as principal character—it was seemingly a cross between the common pheasant and Reeves' pheasant—and such subsidiary characters as "Pertris" and "Pertrisel", the partridges, we see not only the wild life of this corner of eastern England but also the farm life, both human and animal. It is a tragic picture that Mr. Williamson paints, a picture of endless effort to cultivate the stern land, of despair and bitter frustration, of endurance and grim determination that win through, all depicted in the author's well-known vivid style.

F. P.

Interaction of Water and Porous Materials

(Discussions of the Faraday Society, No. 3, 1948.) Pp. ii+294. (London and Edinburgh: Gurney and Jackson, 1948.) 30*s*. net.

THE discussion on this subject held by the Faraday Society during March 31–April 2, 1948, was reported in an article in *Nature* (161, 629; 1948). The full text of the papers has now been published, with accounts of the discussion at the meeting.

STELLAR EVOLUTION AND THE EXPANDING UNIVERSE*

By F. HOYLE
t. John's College, Cambridge

THEORIES of the expanding universe have all been constructed in accordance with the following data:

(*A*) The distribution of nebulæ over the sky is approximately uniform, the approximation becoming better as fainter nebulæ are used in the compilation of the statistics.

(*B*) A relation, discovered by Hubble and Humason, exists between the red shift ($\delta\lambda/\lambda$), usually denoted by δ, of the whole spectrum of a nebula, and its apparent magnitude m. This relation, which can be written in the form

$$\log_{10} \delta = 0{\cdot}2\, m - X, \qquad (a)$$

where X is an observed constant, has been verified for apparent magnitudes less than 18, and is independent of the directions of the nebulæ relative to the earth.

It has been generally accepted that (*A*) can be taken as demonstrating the large-scale homogeneity and isotropy of the spatial distribution of matter, and all theories work in an approximation in which the material in the nebulæ is regarded as being smeared out into a uniform background. In terms of Einstein's theory of general relativity, Weyl interpreted (*B*) as showing that, in the same approximation, the world lines of different elements of material form a bundle of geodesics without envelope that spread outwards from a point. This postulate much simplifies the solution of Einstein's field equations, which, in a common notation, take the form

$$G_{\mu\nu} - \tfrac{1}{2} g_{\mu\nu} G + \lambda g_{\mu\nu} = - \varkappa T_{\mu\nu}, \qquad (b)$$

where λ is a cosmical constant. For, by choosing geodesic co-ordinates, a universal time can be defined that leads to a comparatively simple expression for the line element. A detailed review of the models derived on this basis has been given by Robertson[1].

(*A*) and (*B*) do not exhaust the available data concerning the expanding universe. Thus, Hubble and Tolman have attempted to use:

(*C*) the observed distribution of nebulæ as a function of apparent magnitude,

as a criterion for deciding between the various models satisfying (*A*) and (*B*). It is now generally agreed, however, that a substantial reduction in the errors of measurement is necessary before this criterion can be decisive. The required improvements will eventually be forthcoming from the 200-inch telescope at Mount Palomar. In the meantime, other criteria can be developed from the results of astrophysical research. Among the more important of these results the following may be briefly mentioned:

(*D*) The brightest stars observed in the central regions of nearby spiral nebulæ, in globular clusters and elliptical nebulæ are of closely comparable luminosities. A consideration of the origin and development of these stars yields ages of about 5×10^9 years for the nearby nebulæ. The method used in this determination appears devoid of substantial error; it seems fairly certain that the ages could not be less than 3×10^9 years or greater than 7×10^9 years.

(*E*) In spite of the steady conversion of hydrogen to helium and higher elements, taking place within the stars, which amounts to the transformation in 10^9 years of about 0·1 per cent of the hydrogen present in the nebulæ, hydrogen still constitutes about 99 per cent of all material.

(*F*) The rapidly increasing evidence in favour of the widespread existence of internebular material makes it difficult to resist the conclusion that the nebulæ represent condensations in an internebular medium. The density in such a medium could not be greater than the lowest densities, of about 10^{-25} gm. per cm.^{3}, observed in the nebulæ themselves. On the other hand, the density could not be much less than 10^{-27} gm. per cm.^{3}, otherwise the period required for nebular condensation would become unacceptably large.

(*G*) There is a marked clustering tendency among the nebulæ. Clusters vary greatly in size from pairs of nebulæ up to those containing more than a thousand densely packed members. This indicates that the internebular medium is unstable against the formation of localized condensations; that is, a condensation, following essentially Newtonian dynamics in its internal structure, must be formed wherever the density in a particular region exceeds the mean density in the general background.

We now mention briefly the reasons why models, satisfying (*A*) and (*B*) and equations (*b*), are nevertheless unsatisfactory. The following cases may be distinguished. (i) *Oscillatory universes.* (*F*) and (*G*) can be satisfied, but *E* is an overriding difficulty. These models contain material of finite density but of infinite age. Thus the irreversible conversion of hydrogen into helium and higher elements would have exhausted the hydrogen content of the universe, in contradiction with the observed predominance of hydrogen. (ii) *Universes with zero cosmical constant (excluding oscillatory cases).* These models have a point source origin and are of finite age. But the ages given when (*B*) is satisfied are not appreciably greater than 10^9 years. Accordingly there is a direct contradiction with *D*.

(iii) *Universes with non-zero cosmical constant (excluding oscillatory cases).* It is convenient to treat these models in the following order: (*a*) *The Lemaître–Eddington universe.* By choosing an appropriate relation between the cosmical constant and the density of matter in the uniform background, Einstein found that a static finite universe could be obtained. It was shown by Eddington[2] that this universe is unstable against a perturbation of volume; an increase in volume leading to an unlimited expansion that had been discussed previously by Lemaître[3].

This model is in contradiction with (*D*) and (*G*). For condensations can form only during the pre-expansion stage, on account of the disruptive effect of the cosmical constant. But an infinitesimal perturbation of the Einstein state requires such condensations to have infinite ages. Even for a finite perturbation, such as that considered by Eddington[4], the ages are of order 5×10^{10} years. The origin of a finite perturbation sufficiently large to give ages appreciably less than 5×10^{10} years raises what appears to be a fatal difficulty.

---

* Substance of a series of lectures given at the Royal Institution on October 26, November 2 and 9.

(*b*) *The Lemaître universe.* There is an infinity of point source models possessing unlimited expansion. The nebulæ are not appreciably older than 10^9 years in the models of shortest age. On the other hand, there is a model of infinite age that passes through the Einstein state with infinitesimal velocity. Between these two extremes it is possible to obtain a model with an age of 5×10^9 years. Thus (D) can be satisfied for a suitable choice of the initial conditions.

This model fails, however, as all point source models do, on account of (F). For, in the early stages of expansion, the material in the general background is unstable against the formation of condensations. Thus condensations would be formed in material with density much higher than the mean densities within the nebulæ. No such condensations are observed. Detailed considerations show that this crucial objection cannot be overcome through the action of gas or radiation pressure. (The work of Adams[5], as interpreted by McKellar[6], requires the present background temperature to be not greater than about 1° K., from which it can easily be shown that the thermal energy density is everywhere very small compared with the energy density of matter. Although, according to the theory, the ratio of thermal energy to the rest energy of matter was greater in the past, such an increase in the importance of thermal energy is far from being sufficient to invalidate the present argument.) It may also be noted that, due to the effect of the cosmical constant, G also presents a serious difficulty.

Before considering new possibilities, the suggestion may be dismissed that the universe might be static, the observed red shifts of the spectra of the nebulæ being supposed to arise from some unknown cause. This notion fails for the same reason that oscillatory universes are unsatisfactory. Thus, since a static universe is of necessity of infinite age, no hydrogen could be present on account of the irreversible conversion into helium and higher elements. Nor can the difficulty of obtaining a satisfactory system of cosmology be ascribed to Einstein's formulation of relativity. A similar situation appears to arise in Milne's kinematical relativity, which leads to a universe having considerable similarity with the case, mentioned above, of zero cosmical constant. Indeed, the remarkable demonstration by Milne and McCrea[7], that Newtonian analogues exist for all the models discussed above, clearly shows that the solution of the cosmological problem must be sought in an essentially new concept.

Accepting the red shifts of the nebular spectra as indicating expansion, the outstanding question may be stated in the form: Why do condensations not exist with mean densities much greater than the observed mean densities in the nebulæ ?

At first sight, expansion seems to require that the density of matter in the general background must in the past have been much greater than the observed mean densities in the nebulæ. This leads to the impasse that dense condensations would certainly have been formed. The difficulty can be avoided by supposing that expansion does not require the background density to have been greater in the past. For this condition to be satisfied matter must be created continuously. The idea of continuous creation is not new. Jeans[8], and more recently Milne[9], have discussed the possibility of explaining the origin of the spiral arms observed in many nebulæ in terms of the creation of matter at their centres. Dirac[10] has emphasized the cosmological importance of continuous creation, and this question has been considered by Bondi and Gold[11] and also by the writer[12].

The homogeneity requirement (A) suggests that creation takes place uniformly in the general background, rather than at the centres of the nebulæ, as suggested by Jeans. Weyl's postulate, mentioned above, provides a convenient means of formulating continuous creation in mathematical terms. The main effect is to introduce a new tensor in the left-hand side of (*b*). Putting λ equal to zero, it can then be shown that there is but one steady-state solution of the field equations. Moreover, whatever the initial conditions, this state is reached in a comparatively short length of time.

The condition (G) is satisfied. That is, the material in the background is always unstable against the formation of condensations, although when averaged on a very large scale the density is uniform not only in space but also with respect to the time co-ordinate. The line element is identical with the well-known de Sitter form. This requires a relation (*a*) to be strictly satisfied. The theoretical value of X can be arranged to agree with the observed value by an appropriate choice of the creation-rate, which is the only free parameter in the theory. This leads to a background density of about 5×10^{-28} gm. per cm.^{3}, and a creation-rate of about 10^{-43} gm. per cm.^{3} per sec. The latter value is far too low to be observable in the laboratory.

Bondi and Gold[11] have shown that (C) is also satisfactorily explained in the present model. This agreement with observation is particularly noteworthy, for, once the creation-rate has been fixed so as to give agreement with the observed red shifts, no adjustable parameter remains in the theory (in contrast with many other models), which therefore stands or falls according as to whether (C) is accounted for or not.

Although the present universe is of infinite age, individual nebulæ possess finite ages. Investigation shows that nebulæ observed to be receding from the earth must have theoretical ages lying between 2×10^9 years and about 10^{10} years. The individual field nebulæ are associated with the lower age limit, and the great nebular clusters with the upper age limit; that is, the number of nebulæ contained in a cluster is a measure of its age. According to (D), nearby nebulæ have an age of about 5×10^9 years. This indicates a moderate degree of clustering in the neighbourhood of our galaxy. It is satisfactory that this requirement is in agreement with observation, which shows that our galaxy is a member of a local group of nebulæ.

(E) is satisfied provided the created material consists either of hydrogen or of neutrons. (F) is automatically satisfied for a background density of 5×10^{-28} gm. per c.c.

It is not the purpose of this article to enter into the philosophical implications of the continuous creation of matter. Nevertheless, the following two points may be mentioned. (*a*) The resulting universe possesses both an infinite past and an infinite future throughout which the large-scale properties must remain unchanged. Thermodynamics has only localized significance. There is no large-scale 'running down' towards a general heat death. (*b*) Eddington attached much significance to a coincidence between the observed value of X and a number that can be built up out of the constants of microscopic physics. This coincidence, which is probably of great importance, appears in the present theory as a relation between the creation-rate and the microscopic constants. The existence of this relation is a warning that the theory in its present form is probably far from being complete. At the same time it provides a hope that a deeper understanding of the creation process may ultimately be forthcoming.

INFRA-RED SPECTROSCOPY WITH THE REFLECTING MICROSCOPE IN PHYSICS, CHEMISTRY AND BIOLOGY

By Dr. R. BARER
Department of Human Anatomy, Oxford

A. R. H. COLE*

AND

Dr. H. W. THOMPSON, F.R.S.
Physical Chemical Laboratory, Oxford

DURING recent years infra-red absorption spectroscopy has been applied in a variety of physical and chemical problems. For example, the individualistic character of a molecular vibrational absorption spectrum has been used in the chemical analysis of mixtures of complex organic substances[1], and the constancy of the vibration frequencies of particular atomic groupings assists diagnostic work on polymers and other compounds of high molecular weight, or on substances of chemotherapeutic interest[2]. Another application is the study of the structure of the solid state, and the use of polarized infra-red radiation here promises to give important information[3].

Although it has been possible by means of the so-called 'powder' technique to obtain spectra with only a few milligrams of material, there are many cases—particularly with new antibiotics or other extracts—where even this small quantity is not available, at least in the early stages of an investigation. The matter may also be complicated by having to use liquid paraffin as a base for the powder, since its absorption bands often overlie spectral regions of interest. The desirability of being able to use extremely small amounts of material becomes greater in biological problems such as the measurement of spectra of individual cells, of fibres, or of tissue sections. For all these reasons some form of microscope has long been desirable. Also the applications with polarized infra-red radiation would be much simplified if it were possible to use a small crystal of material or oriented fibre, rather than having a fairly large artificially prepared layer or film.

The microscope has already been used in spectroscopy, both in the visible and ultra-violet[4]. In the latter case, Caspersson[5] and others have used a quartz refracting instrument with success. This method has shortcomings, however, since the instrument must be refocused as the wave-length is changed, and absorption by the system of lenses restricts the spectral range available. The development by Dr. C. R. Burch of a reflecting microscope[6] therefore leads to an important extension of the whole method, since the achromatic nature of the instrument and the entire absence of absorbing materials make it serviceable from the extreme ultra-violet to the far infra-red. Using a continuous source of radiation, such as the hydrogen discharge tube, it has been possible[7] to measure the ultra-violet and visible spectrum of cystals and blood cells. The investigation of spectral changes as different parts of a cell are measured is of great interest.

On the other hand, the use of ultra-violet absorption spectra has certain limitations. Difficulties may arise, for example, because of photolysis; but more important, the band systems of complex molecules are too often composed of broad absorption maxima which are not very specific in revealing the nuclear skeleton of the molecules involved. In this respect, the greater specificity of vibrational spectra in the infra-red has often been emphasized.

We have therefore been fortunate in being able to use the Burch microscope with a Perkin Elmer recording infra-red spectrometer, and have now obtained spectra between 2 and 15 μ of particles, without recourse to slit-widths so large as to reduce the spectral resolution too badly. Prisms of rock salt and lithium fluoride have so far been used, but there seems no reason why the range should not be extended to longer wave-lengths with a prism of potassium bromide. Radiation from a Nernst glower passes through the microscope and sample, emerging to give a magnified image (100–1,000-fold), which can be seen by the eye. The sample is placed on a thin plate of rock salt, quartz or other transparent material. By means of a small preliminary slit of variable aperture, different parts of the object can be selected, and the radiation through these parts directed by means of focusing mirrors on to the entrance slit of the spectrometer. The weight of substance used in the present work is in general 10^{-7}–10^{-8} gm. The minimum size of particle which can be used depends on the resolving power of the microscope, which in turn varies with the wave-length. We have, however, obtained good records with crystals and fibres 20–50 μ in diameter. We have also been able to investigate polarization effects using a selenium mirror following the microscope, the sample under examination being rotated in a horizontal plane.

Some examples of the results so far obtained are described briefly in the following.

(1) It was required to measure the spectrum of a minute crystal of 'bialin', which had been extracted

from the mould *Penicillium Bialowiezense*, and in particular to establish its identity, or otherwise, with a similar small crystal of mycophenolic acid obtained from *Penicillium brevi-compactum* (Dierckx). The spectra proved to be identical over the region 2–14 μ; further, using higher dispersion in the region of 3 μ, the behaviour of the two samples in polarized radiation was exactly similar (Fig. 2, *C*). Any other method of establishing this identity with such small quantities of material would perhaps have been impossible, and chemical methods would certainly have required much more material. Another important point is that the use of paraffin as a base for the powder is avoided, and the important regions of the C—H absorption bands are not obscured.

(2) A small crystal of the anti-pernicious anæmia factor (vitamin B12) isolated by E. Lester Smith[8] was examined with a view to structural diagnosis. From the spectrum shown in Fig. 1 (2), it is seen that the stretching vibrations of CH_2 and CH_3 groups lying near 2,900 cm.$^{-1}$ are comparatively weak, and this is indeed paralleled by the weak nature of the corresponding C—H deformational modes near 1,460 cm.$^{-1}$ and 1,375 cm.$^{-1}$. By contrast, there is a broad region of strong absorption between 3,200 and 3,500 cm.$^{-1}$ which must be due to bonded O—H or N—H groups. This region also appears to have sub-maxima, and one of these may indicate the stretching mode of C—H bonds in an aromatic or heterocyclic nucleus such as the pyrrol or pyrimidine type. The character of the region of O—H absorption is more like that usually found for bonded hydroxyl groups of an alcohol or phenol than that of hydroxyl groups in a carboxylic acid, but further comparison with model substances would be profitable.

Taken as a whole, the spectrum does not show the general features found with a polyamide[9], with which strong bands occur near 1,470, 1,550, 1,640, 2,950 and 3,300 cm.$^{-1}$. The strong band near 1,660 cm.$^{-1}$ may indicate C=C or C=N links rather than peptide C=O groups, which again may occur in a cyclic compound of the kind just mentioned. Correlation of other bands in the spectrum with constituent groups is at present difficult, but it may be noted that, on the basis of other measurements in progress here[10] on the alkyl phosphites, phosphates and phosphonates, there is indication of phosphorus–oxygen links in vitamin B12. If the substance proves after all to be substantially a polyamide in nature, its spectrum must be considerably masked by other parts of the molecular structure.

(3) The spectrum of gramicidin B (Fig. 1, 3) shows the group of five strong bands usually found with polyamides between 1,400 and 3,400 cm.$^{-1}$ as well as the weak band near 3,060 cm.$^{-1}$. In this case the bands at frequencies less than 1,400 cm.$^{-1}$ were broader than usual; but further comparisons with model compounds might lead to correlations with particular amino-acid residues concerned. Samples of insulin gave similar results.

(4) Small quantities of other substances typical of those encountered in biochemistry have been measured, such as cholesterol, tryptophane and methionine. The spectrum of cholesterol (Fig. 1, 4)

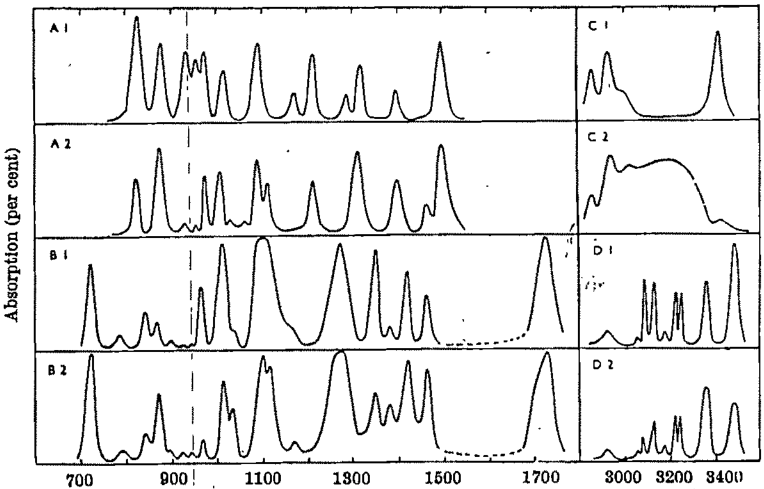

Fig. 2. Polarized radiation

A 1, 2. *p*-Chlorobenzaldoxime crystal, 0° and 90°.
B 1, 2. Terylene fibre, 0° and 90°.
C 1, 2. Mycophenolic acid, 90° and 0°.
D 1, 2. *p*-Nitraniline, 90° and 0°.

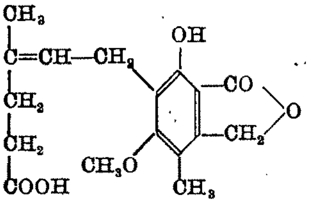
is noteworthy for its relative simplicity, the marked bands due to C—H vibrations and the weak O—H band near 3,420 cm.$^{-1}$. We would again emphasize here the advantages of obtaining the spectra in absence of 'Nujol'.

(5) We have also measured the spectra of fibres, including hair, casein, terylene, muscle and nerve fibres. The spectrum of frog nerve (Fig. 1, 5) shows the main features of a polyamide; but after a rough extraction with chloroform there are marked alterations in the relative intensities of certain bands. This extraction diminishes the strength of the stretching and bending vibration bands of C—H bonds near 2,900, 1,460 and 1,375 cm.$^{-1}$ and causes the bonded O—H group to appear more intense. This is what would be expected for the removal of lipides. The reduction in intensity of the band near 1,080 cm.$^{-1}$ is also consistent with the removal of —C—O— bonds such as occur in esters[11], and in this connexion it is interesting that the strong band near 1,235 cm.$^{-1}$ appears to be in the polyamide rather than the lipide.

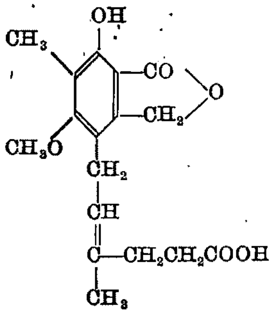
The spectrum of frog muscle (Fig. 1, 6) also shows the main features of a polyamide, but at frequencies less than 1,500 cm.$^{-1}$ there are definite differences from the spectrum of nerve, and the relative intensities of the C—H and bonded O—H vibration bands are different in the two cases. It is clear that a more detailed study of this whole problem might be very informative.

(6) The use of polarized infra-red radiation for studying the internal structure of crystals, ordered crystalline aggregates and oriented polymers was previously investigated by Mann and Thompson[12], and later extended by Ambrose, Elliott and Temple[13] and by Jones and Sutherland[14]. Its value in the present work is greater because small single crystals can be used without the need of obtaining large uniformly oriented films, fibres can be studied at successive stages of 'drawing' or orientation, and very small areas of polymer films can be used. Alternatively, in the latter case small areas in a large film of polymers can be studied to compare the degree of order in the structure.

A number of substances were measured for comparison with the earlier work on a macroscopic scale, such as acetanilide and adipic acid, and full agreement was found. Fig. 2 (*D*, 1, 2) shows the spectra of small crystals of *p*-nitraniline near 3 μ, and (*A*, 1, 2) of *p*-chlorobenzaldoxime between 7 and 14 μ, with the incident electric vector respectively parallel and perpendicular to the crystal axis. This figure also shows the corresponding results for terylene between 7 and 14 μ (*B*, 1, 2) and mycophenolic acid near 3 μ (*C*, 1, 2). The change in spectrum with mycophenolic acid between 2,800 and 3,600 cm.$^{-1}$ is interesting since it reveals the simultaneous existence of two types of O—H bond, one feebly and the other strongly 'bonded'; and the bonded type behaves like a carboxylic hydroxyl group. This result is consistent with the structure which has been assigned to the substance in the sense that it has been thought to contain both a carboxyl group and a phenolic hydroxyl group. There has been doubt, however, about the relative positions of the substituents around the aromatic nucleus, the formula being either (*a*) or (*b*)[15]; and it seems on the basis of the present results to suggest (*a*) rather than (*b*), since in the case of (*a*) the steric effects might be more likely to prevent association of the phenolic hydroxyl group.



(*a*)



(*b*)

In the case of terylene, the polyester from terephthalic acid and ethylene glycol, marked changes of intensity are found between 7 and 14 μ, although the band near 1,720 cm.$^{-1}$ due to the carbonyl groups is little affected by directional change. The details of this case will be discussed in relation to the crystal structure elsewhere[16], but we would emphasize here the spectral difference detected with fibres which have been 'drawn' to different extents; and even using unpolarized radiation, some spectral changes have been found between stretched and unstretched samples which can be interpreted in terms of special orientation of certain bonds.

The application to individual small crystals such as those of *p*-chlorobenzaldoxime opens up the possibility of cutting crystals along several principal directions, and thence, from computation of intensity of key bands, the deduction of the crystal structure projections on several planes.

In connexion with the carcinogenic activity of certain derivatives of *p*-dimethyl aminostilbene, it has been suggested that coplanarity or otherwise of the two aromatic nuclei may be related to the electronic structure requisite for activity[17]. Since characteristic bands are now known for the several kinds of substituted aromatic nucleus, the use of polarized radiation in crystals of these compounds might throw light on this problem[18], and measurements of this kind are now being made.

(7) Another line of work which can now be explored is the infra-red spectral absorption of biological cells. We have made preliminary measurements with several samples such as blood, and obtained good spectra. If the intensity of the source of radiation and the numerical aperture of the microscope can be increased, as seems possible in several ways, it should become feasible to examine different parts of the single cell and, in some measure at least, to investigate variations in chemical composition. The possibility of following cellular processes continuously, using the cathode ray tube infra-red recorder, may then be realized.

These examples serve to illustrate the manifold applications which may now be made using the new microscope. There are numerous possible improvements, such as the construction of a microscope of greater aperture, and the provision of a more intense beam of radiation. It seems, however, established that the method will not only form an important step forward in crystal analysis, but also a valuable weapon in much biological work.

We wish to express our appreciation to the Nuffield Foundation for a grant in aid of equipment to be used with the microscope, and also to the American Cyanamid Company for the generous gift of the

infra-red spectrometer used. We are also grateful to all those who have provided materials for study.

OBITUARIES

Dr. Marjory Stephenson, M.B.E., F.R.S.

MARJORY STEPHENSON was born at Burwell in Cambridgeshire on January 24, 1885; she died in Cambridge on December 12, 1948. She was educated at Berkhamsted School for Girls, and at Newnham College, where she was later to be associate and fellow. As circumstances prevented her following her wish for a medical degree, she equipped herself at the Gloucestershire Training College of Domestic Science, and taught for a time there and at King's College of Household Science, London. Soon she had an opportunity to begin biochemical research work at University College, London, under Dr. R. H. A. Plimmer; her first paper, on animal lactase, was published in 1912. The next year she was aided by a grant from Newnham College, and a little later was awarded a Beit Memorial Research Fellowship; but her newly begun career was interrupted by the First World War. She served with the British Red Cross during 1914–18, first in France and then in Salonika, where she was V.A.D. commandant. Her work was recognized by the award of the M.B.E. and the Royal Red Cross.

In 1919 she returned to research, this time at the Biochemical Laboratory, Cambridge, with Sir Frederick Gowland Hopkins. At first she took part in the vitamin work already in full swing in the Laboratory, becoming interested in the fat-soluble vitamins. This interest led on to her work, with M. D. Whetham (later Mrs. A. B. Anderson), on the fat metabolism of the timothy grass bacillus, and thence to more general studies of these and of fermenting organisms. She had now found her life-work and remained in Cambridge, in the favourable milieu of Hopkins' department, developing the science of chemical microbiology, and teaching and inspiring a long succession of pupils and collaborators. Her influence became world-wide; she opened up several new fields of study, some of which have since been brilliantly developed by her pupils.

As time went on, Dr. Stephenson became more and more impressed by the importance of chemical microbiology as a special discipline, not only valuable to the community on account of its industrial and medical aspects, but also capable of making a unique contribution to the progress of scientific thought. This theme she developed in her lecture before the congress which celebrated the centenary of Pasteur in Paris in November 1946. For many years she was on the staff of the Medical Research Council, and in 1944 her tireless efforts led to the formation of the Council's Unit for Chemical Microbiology. In 1948 she was appointed to a University readership at Cambridge. She also played a great part in the founding of the Society for General Microbiology and was its president at the time of her death; many will long remember the charm and lively enthusiasm with which she presided over its conference last September. Three years earlier, she and Dr. Kathleen Lonsdale had been the first women to be elected into the ordinary fellowship of the Royal Society.

Her book "Bacterial Metabolism", which so greatly enhanced her international reputation, appeared first in 1930. The third edition, entirely re-written, is now on the point of publication. It is animated throughout by the imaginative insight which enabled her to consider the microbe, not as a useful device or as a pest to be eliminated, but as a living organism going about its own legitimate business.

In her early work, for example, with J. H. Quastel and L. H. Stickland, she dealt with several subjects of which time has only emphasized the importance—for example, the role of —SH groups in metabolism, or the possibility of energy provision under anaerobic conditions by the interaction of specific hydrogen donators and acceptors. She was the first to demonstrate, in cell-free extract, the presence of a specific (lactic) dehydrogenase from bacteria, and her work on hydrogenase and hydrogenlyase (with L. H. Stickland, D. D. Woods and J. Yudkin) has become classical. The observations on these enzymes aroused her interest in the subject of adaptive enzymes, to which she and her school (now including E. F. Gale) made outstanding contributions.

In 1937 she became interested in the importance of nucleic acid derivatives in cell metabolism, and with characteristic thoroughness embarked on a study (with A. R. Trim) of the changes which the adenine compounds themselves undergo in the presence of bacterial enzymes, as a preliminary to studying their mode of action in the cell. Several years later she came back to the theme of nucleic acid metabolism, and her last paper (with J. Moyle), just ready for press, is on this subject. Her latest published experimental paper (with E. Rowatt) was on the bacterial synthesis of acetylcholine.

During the Second World War, Dr. Stephenson carried out (with R. E. Davies) some important research on the acetone–butanol fermentation, and took a very active part on the Medical Research Council Committee for Chemical Microbiology.

Throughout her years in the Cambridge Biochemical Laboratory, Dr. Stephenson was greatly sought as friend and adviser. She was always ready to pay sympathetic attention, and her advice, usually given quickly and with decision, was based on a deeply considered philosophy of life. One of her great characteristics was her intense interest in people, and a favourite theme in her conversation was the influence of character upon scientific achievement or, conversely, the effect of certain types of results upon the psychology of research workers. She had many interests outside biochemistry, and this fascination by human nature was very plain in her love of the drama and the great nineteenth-century novelists; she was enthralled, too, by the history of the development of civilization and by certain aspects of the theory and history of science. She used to say that, when her laboratory life was ended, she would like to use the leisure of retirement to write biographies of a few of the men of science (Pasteur and Hopkins among them) whom she so greatly admired, and whom she felt that she in some degree understood. In one of the last conversations I had with her, the subject of present-day growing-points in science came up. It was characteristic of her to say: "Let us consider: if Hoppy had started research in Cambridge to-day instead of fifty years ago, where would he have chosen to begin?"

In her later years her interests seemed to grow wider. She had always loved gardening, and she became very keen on horticultural research. She was greatly concerned about the development of biochemical training in general in Great Britain; she was a great advocate of decentralization, and liked to see good workers from more remote places return to act as foci of progress in their own country.

One of her great qualities was her hatred of any form of cant, hypocrisy, pretention or slovenliness; she was ruthlessly outspoken in her condemnation of any such suspected defect. But this personality, so lively and so gifted with the capacity for leadership, had another characteristic: a fundamental humility, which enabled her to listen, learn, and, if need be, change her mind. She had, lastly, a great opinion of the possibilities of youth, and when the risk was debated of entrusting responsibilities to the young, her advocacy was always on their side. She would have applauded Confucius when he said: "The rising generation is to be respected. Who knows what they may accomplish?"

DOROTHY M. NEEDHAM

Mr. T. Petch

MR. TOM PETCH, the well-known mycologist, died at North Wootton, King's Lynn, on December 24 at the age of seventy-eight, after a short illness. Born at Hornsea and brought up at Hedon, he attended the choir school of Holy Trinity, Hull. From Hull and from Yorkshire naturalists he early acquired great interest in plant and animal life, and contributed many original observations to *The Naturalist* and to the Hull Scientific and Field Naturalists' Club.

As a young man Petch taught science and mathematics at King's Lynn Grammar School, and by dint of private study graduated in both arts and sciences at the University of London. At King's Lynn he came under the stimulating influence of the late Dr. C. B. Plowright, then in the very front rank of students of the fungi, and it was this happy contact that led Petch to devote chief attention to the study of these organisms. Later, he taught at the Leyton Technical Institute. One of his friends at this time was the late Mr. George Massee, of Kew, through whom in 1905 Petch was offered the post of Government mycologist in Ceylon at the Royal Botanic Gardens, Peradeniya. He accepted enthusiastically because the post promised greater scope for his interests.

Petch's arrival in Ceylon coincided with a great extension of rubber plantations. He studied in detail the fungus diseases of the rubber tree, then beginning to cause concern, and his researches in this field were most illuminating. In 1911 he published "The Physiology and Diseases of *Hevea brasiliensis*", and in 1921 "The Diseases and Pests of the Rubber Tree", for many years the best books on the subject, acclaimed by men of science and planters alike. He also gave much attention to the diseases of other crops, notably coco-nuts and tea. His book on the "Diseases of the Tea Bush", published in 1923, is a comprehensive account of the pathology of this plant and is still the standard work.

In 1925 Petch left Government service to become the first director of the new Tea Research Institute of Ceylon, which he launched with great success. Being a man of wide vision, he realized that there were many problems in tea production besides the incidence of disease, so he gathered around him a team of experts competent to explore the whole field of inquiry. Petch had the great gift of inspiring enthusiasm and harmony among his colleagues and confidence among the planters. Both the tea and rubber plantation industries are under a deep debt of gratitude to him for most valuable services.

Petch also devoted much attention to the general study of the fungi, mycetozoa, and flowering plants of Ceylon, for he was no mean botanist as well as a brilliant mycologist. For several years he edited the *Annals of the Royal Botanic Gardens, Peradeniya*, which contains numerous contributions from him, among them being "The Mycetozoa of Ceylon", "The Fungi of Certain Termite Nests", "The Phalloideæ of Ceylon", "Revisions of Ceylon Fungi", "Additions to Ceylon Fungi", and "Studies in Entomogenous Fungi". He left Ceylon in 1928 with the reputation of being the world's foremost tropical mycologist.

On retirement to England, Petch devoted the remaining twenty years to the study of fungi, chiefly British groups. His only other major interest was his large garden at North Wootton, which had been designed by the late Dr. C. B. Plowright. Petch was still a most ardent collector and investigator of micro-fungi, and a constant stream of papers emanated from him, published chiefly in the *Transactions of the British Mycological Society*. Among them may be mentioned "British Hypocreales", "British Nectrioideæ", "British Entomogenous Fungi", and a long series on other entomogenous fungi. One of his last efforts was to compile, with Dr. G. R. Bisby, a revised list of Ceylon fungi. Petch had numerous mycological correspondents throughout the world, whom he was always ready to help. He was a most versatile, careful and critical worker, and he corrected many errors of description and nomenclature made by others.

Unfortunately, few honours came Petch's way; but one which he much appreciated was the conferment of honorary membership of the British Mycological Society, of which he had been president in 1920. He was also president of the Yorkshire Naturalists' Union in 1931. Petch was a Yorkshireman of decided but completely honest views, the staunchest of friends, and a most interesting companion.

Petch married in 1908 the daughter of the late Dr. C. B. Plowright, of King's Lynn, who survives him, together with a son and a daughter. His extensive mycological collections have been bequeathed to the British Museum (Natural History).

F. T. BROOKS

M. Georges Truffaut

BY the sudden death in September last of M. Georges Truffaut, science has lost an international figure. Married to an Englishwoman, he spent much time in Britain during his younger days, and frequently visited Rothamsted, East Malling, Long Ashton and Cheshunt. From each of these he gathered much that interested him, and he created at Versailles a laboratory in which he conducted much research on partial soil disinfection, in which he was inspired by the ideas of Sir John Russell. He investigated the bacterial fixation of nitrogen under the influence of electric light, work initiated, or at least inspired, by his work at Rothamsted, and later, in his Versailles laboratory, his attention was led towards the use of colouring matters, at first in agriculture and later in horticulture.

Truffaut was early involved in the determination and use of various colouring matters as weed eradicants. In 1936 he was invited by the Royal Horticultural Society to visit London to put forward the results of his work, at a time that the utilization of 'Sinox' was still in its infancy. As things turned out, he and his laboratory were not able to carry out the extension of their programme as was done in the Anglo-Saxon countries, but they contributed to the development of the processes to the full measure of their abilities. In his last days Truffaut was occupied in working out a new formula for weed eradication which was more economic as well as more active; but his death occurred before these could be put forward. Had he lived, we should probably have heard more of him and his work in connexion with weed eradication.

WE regret to announce the following deaths:

Dr. Andrew Connal, O.B.E., formerly director of the Medical Research Institute, Lagos, on January 26.

The Right Hon. Lord Melchett, formerly deputy chairman of Imperial Chemical Industries, Ltd., on January 22, aged fifty.

Prof. John Percival, emeritus professor of agricultural botany in the University of Reading, on January 26, aged eighty-five.

NEWS and VIEWS

Chemistry at the Australian National University: Prof. Adrien Albert

DR. ADRIEN ALBERT has been appointed the first professor of chemistry in the John Curtin School for Medical Research, Australian National University. Arrangements have been made for the Department of Chemistry to be located temporarily in the Wellcome Research Institution, 183 Euston Road, London, N.W.1, until the necessary buildings have been erected in Canberra, when Prof. Albert will supervise their completion and equipment. Prof. Albert graduated in the University of Sydney in 1932 with honours in chemistry, and in 1937 was awarded the degree of Ph.D. of the University of London. He returned to Australia in 1938 as a research fellow in the Organic Chemistry Department of the University of Sydney, where he remained until 1947. He has recently held a research fellowship at the Wellcome Research Institution.

Defence Services Research Facilities Committee

AT the invitation of the Council of the Royal Society, the Lords Commissioners of the Admiralty, the Army Council, the Air Council and the Ministry of Supply have appointed representatives on a Defence Services Research Facilities Committee. The terms of reference of the new Committee are as follow: "To consider proposals for the use of Service facilities and personnel for assisting scientific research, and to make recommendations to the Council of the Royal Society, the Lords Commissioners of the Admiralty, the Army Council and the Air Council". The Committee has been constituted as follows: *Chairman*, Sir Geoffrey Taylor; *Royal Society*, Prof. P. M. S. Blackett, Sir Harold Spencer Jones, Dr. A. C. Menzies, Mr. F. S. Russell; *Admiralty*, Vice-Admiral A. G. N. Wyatt (hydrographer), Mr. F. Brundrett (C.R.N.S.S.); *War Office*, Lieut.-General Sir Kenneth Crawford (D.C.I.G.S.), Dr. O. H. Wansbrough-Jones (scientific adviser to the Army Council); *Air Ministry*, Air Vice-Marshal C. E. N. Guest (assistant chief of Air Staff—Operations), Mr. G. S. Whittuck (head of S.6); *Ministry of Supply*, Dr. F. J. Wilkins (principal director of scientific research—defence), Mr. H. M. Garner (principal director of scientific research—air).

The Committee proposes to conduct its business through panels of scientific men and Service representatives who are specially interested in specific projects, and at its first meeting panels were formed to cover the following subjects: (*a*) submarine gravity measurements, (*b*) surplus explosives, (*c*) magnetic survey, (*d*) aerial photography, (*e*) scientific expeditions. Scientific workers wishing to submit proposals for consideration by the Committee should communicate their suggestions in the first instance to the Assistant Secretary, Royal Society, Burlington House, London, W.1.

Giant Sunspot and Geomagnetic Storm

A VERY large group of sunspots of 'bipolar' type crossed the solar disk during January 16–29. At central meridian passage on January 22·7 U.T., the middle of the group passed 28° above the centre of the disk. Two big spots were the chief components, with their centres separated 12° in longitude, or approximately 85,000 miles. The aggregate area of the spots for several days was about 2,300 millionths of the sun's hemisphere, or about 55 times the cross-section area of the earth. Greenwich data show that sunspots of this order of size are very likely to be associated with geomagnetic storms beginning within the time-limits of two days before and four days after central meridian passage of the spot group. A severe geomagnetic storm did, in fact, occur, commencing abruptly on January 24 at 18h. 28m. U.T. The disturbance continued with even increased vigour to the night of January 25–26. Displays of the aurora were widely seen on both nights in Great Britain. Provisional overall ranges recorded at Abinger of the earth's magnetic elements (kindly communicated by the Astronomer Royal) are as follow: D, 1° 29′ ; H, 660 γ ; V, 490 γ. Long-distance radio-communication was seriously affected during the period of the geomagnetic storm.

Although a close connexion between the magnetic storm and the solar region containing this giant spot group can scarcely be doubted, there is little evidence at present for the occurrence of a brilliant solar flare some 24 hours before storm onset. Such a flare may have occurred, however, during the Greenwich night hours, and observations are being sought from observatories recording during 18h.–0h.–6h. U.T. either (*a*) direct solar observations; (*b*) radio anomalies that occur in the earth's day hemisphere when flares occur; or (*c*) a characteristic 'crochet' impulse on magnetograms that likewise betrays the occurrence of the more intense flares. Apart from this, there is increasing evidence that the stream of solar particles involved in the occurrence of a great magnetic storm is ejected at the time of an intense flare within the central region of the sun's disk.

Geological Survey in the British Commonwealth

In an article in the *Petroleum Times* of January 1949, a "Petroleum Geologist" puts forward proposals for a British and Commonwealth plan for a modern geological survey. He lays emphasis on the fundamental importance of geological survey, and on the urgent need for an appraisal of the mineral resources of the Commonwealth. He recognizes that the development of the surveys depends on the expansion and training of staff and on the provision of specialist services in such fields as palæontology, geophysics and air survey. The lay-out of the organisation which he advocates accepts the essential independence of the surveys of the several Dominions, but involves a closer relationship between the Geological Survey of Great Britain and the Colonial geological surveys; he proposes that these should be placed under a Minister (or his nominee) with an advisory board, and that specialist services should be joint. The comparison with the organisation of some oil companies is not helpful, however; both in Britain and in the Colonies, geological surveys have a much wider range of interest than an oil company, and procedures suitable for the rapid exploration of oil resources are not necessarily adaptable for a survey which, to be economical, must deal concurrently with many topics. Moreover, while it is true that greater freedom of interchange between Britain and the rest of the Commonwealth is valuable, the differences in the nature of the problems met with, and the importance of individuals with great local knowledge, limit the possibilities of useful interchange. We believe that the Geological Survey of Great Britain is itself as fully engaged on economic problems as "Petroleum Geologist" could desire, while the new organisation of the Colonial surveys promises important and rapid progress as men can be recruited.

Autumn Bird Migration in Britain

Several very interesting items occurred during the autumn of 1948 with bird movements in Britain. On August 21 and 22 an American greater yellowshank (*Totanus melanoleucus*), the sixth British record, appeared at Ecton Sewage Farm, Northamptonshire, where a grey phalarope, the first county record since 1902, and an osprey appeared in September. On September 13 an American pectoral sandpiper (*Calidris melanotis*) appeared at Salthouse Marsh in Norfolk, another was reported from Sinderland, in Cheshire, on September 10, and a third at Thorney Island, Sussex, on October 3. On September 9 an immature cormorant (*Phalocrocorax carbo*) with four legs was obtained at Seaforth, Lancashire; later it died in Liverpool, but X-ray and other photographs were taken for the Merseyside Naturalists' Association. A grey phalarope also appeared at Worsley Sewage Farm, Lancashire, on September 5. On November 11 a little bunting (*Emberiza pusilla*) was added to the bird records of Cumberland by R. Stokoe, a careful observer, at a roadside pool at Siddick, near Workington. Whooper swans were on the same water, and earlier that month on Derwentwater. A gadwall was shot at Frodsham, Cheshire, early in December. Ringed bird returns have included this season a turnstone in Cheshire, marked by Stavanger ornithological station in Norway; and a Manx shearwater found at Leigh, Lancashire (an inland location), on September 5, was marked at the Skokholm colony, South Wales, as recently as August 28.

The Animal Health Trust

Reviewing the ten-monthly period ending June 1948, the second report of the Animal Health Trust describes the completion of the requisition of land and buildings for the Trust's Canine Research Station at Newmarket and the Farm Livestock Research Station at St. Ives. At the former, research has been restricted to studies of a clinical nature including para-distemper, night blindness and Scotch cramp, while at the Poultry Research Station, established on the fifty-acre parkland adjoining Houghton Grange, St. Ives, diseases of the respiratory track have been the priority subjects of investigation. Progress has also been made in the investigations being carried out at the Equine Research Station at Balaton Lodge and Lanwades Park, Newmarket, into infertility, parasitology and diseases of foalhood. During the ten months, the Trust has granted a number of research fellowships to individual workers who wished to continue investigations of an independent nature, and helped some veterinary surgeons to go abroad to widen their experience. Six county committees of the Trust have been formed and eleven others are in the process of being established.

Zoological Society of Bengal: New Journal

Zoologists will be interested in the appearance of vol. 1, No. 1 of the *Proceedings of the Zoological Society of Bengal*, which, it is announced, will be published twice yearly and will contain the results of original research in the various branches of zoology. The first number (obtainable from the Society at 35 Ballygunge Circular Road, Calcutta; price 5 *Rs.* or 10*s.*) comprises 78 pages and 4 plates; and it contains eight papers covering a wide field, contributed mainly by the Department of Zoology of the University of Calcutta. S. P. R. Chaudhuri and I. Bose give an account of meiosis in diploid and tetraploid spermatocytes of the grasshopper *Attractomorpha* sp., while meiosis and chiasma formation in another grasshopper, *Tristria pulvinata*, is the subject of a paper by M. K. Dutt. In a study of the scales in *Glossogobuis giuris*, S. Mookerjee shows that the ctenoid condition is an advance on the cycloid which occurs earlier in development. The bionomics and reproduction of another fish, *Ophicephalus striatus*, are discussed by H. K. Mookerjee, D. N. Ganguly and R. N. Bhattacharya, and R. P. Dhar contributes a hæmatological note on a closely allied species. Some myxosporidians parasitic in fishes are described by M. Chakravarty and S. P. Basu. Termite control with various insecticides tried out in the field is the subject of an investigation by D. Mukerji and P. K. Mitra, and the final paper, concerning the development of the vertebral column in *Alligator mississippiensis*, is by H. K. Mookerjee and R. N. Bhattacharya. Text and figures are clearly printed on good art paper.

Preslia: Botanical Research in Czechoslovakia

THE Czechoslovak Botanical Society has just published a comprehensive issue (vols. 22 and 23, pp. 248) of its proceedings, *Preslia*, for the years 1943–47. The periodical, named after the brothers J. S. and K. B. Presl, who flourished in the first half of the last century, had been an annual publication for some time before the War, but nevertheless served as a repository for the results of botanical research in Czechoslovakia. The Society now has an active membership of more than two hundred, besides that of some twenty-nine (pre-war, thirty-seven) affiliated societies and naturalists' clubs. During the period under review it was mainly through these that botanists were able to continue working and publishing. The current issue of *Preslia* lists these contributions for the years 1939 to 1947 as well as describing (in English and Czech) the recent history of some of the affiliated institutions. Some institutes are still not in working order. Dr. I. Klašterský is held up with his work on the genus *Rosa*; Prof. J. Peklo lacks facilities for his phytopathological studies, and Prof. K. Domin cannot obtain the foreign literature he needs for comparative purposes. So far as botany is concerned, Slovakia appears to have suffered less than Bohemia, though Prof. B. Němec states that the Bratislava University Institute for Plant Physiology lacks microscopes and other equipment, and is without a proper library. A note in *Preslia* refers to the failure of the Botanical Society to obtain a grant from Unesco through the Association Internationale des Microbiologistes, and this is likely to delay further publication. In 1938 a group of botanists founded a journal, *Studia Botanica Cechoslovaka*. It survived until 1943, and hope is now expressed that it will resume publication under the editorship of Prof. S. Prát and Dr. I. Klašterský.

Toxicity of Certain Synthetic Organic Compounds to Insects

THIS subject is discussed in the *Canadian Journal of Research*, June 1948, in a paper divided into two parts. In Part 1 Messrs. A. W. A. Brown, D. B. W. Robinson, H. Hurtig and B. J. Werner record their results from testing the general toxicity of some 127 synthetic compounds when mixed in graded concentrations in the food of the larvæ of the housefly (*Musca domestica*), the confused flour beetle (*Tribolium confusum*), the Mediterranean flour moth (*Ephestia Kuhniella*) and adults of the granary weevil (*Sitophilus granaria*). Each compound was intimately mixed with the food medium in which each of the foregoing insects lives and feeds. The method of testing gives an overall measure of the contact, stomach, and fumigant action of each compound without distinction as to its mode of action. The most highly toxic substances were found to be 'Gammexane' (the gamma isomer of hexachlorocyclohexane) and chlordane (obtained by the distillation of technical chlordane). The toxicity of D.D.T. was, on an average, one half of that of these two compounds. In Part 2 Messrs. A. W. A. Brown, B. J. Werner and F. E. Park record the results of their experiments regarding the direct toxicity of 91 compounds against the nymphs of the German cockroach (*Blatella germanica*) and of the large milk-weed bug (*Oncopeltis fasciatus*), continuously reared in the laboratory on seeds of *Asclepias syriaca*, and also adults of the confused flour beetle (*Tribolium confusum*). The compounds used were dissolved in graded concentrations in a benzine-kerosene mixture and sprayed on the insects confined in a cylindrical glass spraying tower 29 in. high. Compressed air was applied to an atomizer at a uniform pressure of 23 cm. mercury. Taking the results with the three species of insects as a whole, the highest contact toxicity was shown by 'Gammexane' and chlordane. Dinitro-*o*-cresol and dinitrocyclohexylphenol were next in order of effectiveness. The results described in the two parts of this paper are based on tests carried out at the Experimental Station, Suffield, Alberta.

International Veterinary Congress

THE Fourteenth International Veterinary Congress will take place in London during August 8–13, 1949, and the meetings will be held at the Central Hall, Westminster, and in Church House, Westminster, S.W.1. The Duke of Gloucester, who is the president of the Royal Veterinary College and Hospital of London, hopes to be able to open the Congress. As it is considered that the present world food situation is the most important scientific and practical question of the day, the programme of the Congress has been based on this theme. Every morning there will be a plenary session at which a paper will be presented by a leading authority on the veterinary profession's contribution to some aspect of world food production. Sectional meetings will be held in the afternoons, and the programme for these is designed to cover a wide range of subjects. The executive committee has been appointed as follows: *President*, Sir Daniel Cabot; *vice-president*, Prof. J. B. Buxton; *honorary secretary*, Dr. W. R. Wooldridge; *honorary treasurer*, Mr. G. N. Gould; *general secretary*, Mr. W. G. R. Oates. An exhibition of the latest instruments, appliances, drugs, disinfectants, books, etc., will be arranged near to the Central Hall. Social functions have been arranged for the evening of August 7, and during the week of August 15–20 excursions will be made to places and establishments of veterinary interest. Official invitations to the Congress have been issued by the Government of Great Britain to foreign, Commonwealth and Colonial Governments. Representation has been invited not only from government veterinary departments, but also from universities, veterinary schools and other interested bodies in every country. Persons desirous of attending the Congress should apply as early as possible, and all inquiries should be addressed to the Organising Secretary, Fourteenth International Veterinary Congress, 10 Red Lion Square, London, W.C.1.

Fourth Empire Mining and Metallurgical Congress

A NOTE on the coming Fourth Empire Mining and Metallurgical Congress has already been published in *Nature* (October 16, p. 606). A second circular on this Congress is now available, and in it details are to be found relating to the inaugural programme in London for July 9–12 and to the technical sessions to be held in Oxford during July 13–17. In Oxford the main subjects for discussion will be: mineral resources of the Commonwealth; modern methods of prospecting; physiological and psychological effects of heat and humidity on workers in deep mines and in metallurgical works; petroleum—with special reference to the world oil position, oil-well drilling practice and its application to petroleum exploration; coal—with special reference to resources of the Commonwealth, the characteristics of Empire coals and modern coal-mining practice in Great Britain; present-day trends in mineral dressing; and metallurgy and metallurgical industries. Also in this circular full details are given of the excursions during July 18–23. The programme consists of visits, based on Cardiff, Cornwall, Edinburgh, Manchester, Newcastle-upon-Tyne, Sheffield and Stratford-upon-Avon, which will be made to collieries, iron and steel works, hydro-electric schemes, shipbuilding yards and other places of technical interest, together with a number of excursions of historical and general interest. Further information may be obtained on application to the Joint General Secretaries, Fourth Empire Mining and Metallurgical Congress, 436 Salisbury House, Finsbury Circus, London, E.C.2.

Applications of Ultrasonics

THE Acoustics Group of the Physical Society has arranged to hold a discussion meeting on the applications of ultrasonics at th Imperial College, London, S.W.7, at 2.15 p.m. on February 18; Mr. G. Bradfield will read a review paper and Mr. J. M. M. Pinkerton will outline the application of ultrasonics to the investigation of molecular structure. These papers will be followed by sixteen invited contributions covering the majority of present applications: other workers in supersonics who may wish to contribute should write to the Joint Honorary Secretaries of the Acoustics Group of the Physical Society, 1 Lowther Gardens, London, S.W.7.

Committee on Exports and Imports of Cattle Semen

THE Minister of Agriculture and Fisheries and the Secretary of State for Scotland have appointed a Committee with the following terms of reference: "To advise on the considerations which should govern the granting of licences for the export and import of cattle semen for the purposes of artificial insemination and on any other problems related thereto". The Committee is constituted as follows: Lord Oaksey (*chairman*), Col. S. E. Ashton, Sir John Barlow, Dr. J. Hammond, Mr. E. O. Jones, Mr. Alexander Keith, Prof. W. C. Miller, Mr. Duncan M. Stewart, Mr. W. R. Trehane and Mr. W. J. Wright. The secretary to the Committee is Mr. R. Harding Wynne of the Ministry of Agriculture and Fisheries, 14 Chester Terrace, Regent's Park, London, N.W.1.

Science Masters' Association: Scottish Branch

THE annual general meeting of the Scottish Branch of the Science Masters' Association will be held in St. Leonard's School, St. Andrews, during April 12–14, under the presidency of Sir James Irvine. The principal speakers will be Prof. John Read, Prof. A. D. Peacock, Dr. Freundlich and Dr. Steel. They are to give addresses on "Giant Molecules", "Darwinism Up-to-Date", "The Problem of Evolution in Astronomy" and "Tidal Power", respectively. Visits have been arranged to the works of the Cash Register Co., Guardbridge paper mills, the sugar beet factory at Cupar, and elsewhere. Publishers and scientific instrument makers are also taking part.

Announcements

SIR WALLACE AKERS, a director of Imperial Chemical Industries, Ltd., has been appointed a trustee of the National Gallery.

IT is announced from the University of London that Mr. Ronald King has been appointed to the University readership in physics tenable at University College as from January 1. The following doctorates have been conferred: *D.Sc.*, Mr. Hans Grüneberg (reader at University College), Mr. S. E. Jacobs (Imperial College), Mr. R. C. Jordan (Imperial College); *D.Sc.* (*Econ.*), Mr. S. M. Dhumé (London School of Economics).

A NEW open scholarship, worth up to £1,000, is being offered by the Textile Institute, and applications are invited both from those already engaged in the textile industry and from those still at school who propose to study textile technology. The scholarship is intended to provide facilities for a three years course of study in textile technology to an advanced stage and for industrial experience in Great Britain and abroad. Details and application forms are available from the General Secretary, Textile Institute, 16 St. Mary's Parsonage, Manchester, 3.

THE Ministry of Agriculture and Fisheries and the Department of Agriculture for Scotland propose to award, for the academic year beginning October 1, 1949, a limited number of postgraduate scholarships in husbandry, agricultural economics, statistics, and agricultural and dairy engineering. The closing date for applications is May 15, 1949. Further particulars may be obtained from the Secretary, Ministry of Agriculture and Fisheries, 1/4 Cambridge Terrace, Regent's Park, London, N.W.1, or the Secretary, Department of Agriculture for Scotland, St. Andrew's House, Edinburgh, 1, according to the country of residence. Applicants resident in Northern Ireland should apply to the Ministry of Agriculture and Fisheries, London, at the above address.

A CONFERENCE on Mental Health will take place at Seymour Hall, Seymour Place, London, W.1, on March 17 and 18, 1949. Applications for tickets and all correspondence should be addressed to the Conference Secretary, 39 Queen Anne Street, London, W.1.

THE date of the Fifth International Congress of Comparative Pathology in Istanbul (see *Nature*, November 27, p. 844) has been put forward to April 22–29, 1949.

REFERRING to his article on "Ancient Arts and Modern Parodies" in *Nature* of January 22, p. 146, Mr. William Fagg states that the last sentence of the second paragraph should read, "Less easy to explain is the omission of the truly primitive sculpture of Borneo . . ."

Elementary Particles and the Principle of Reciprocity

THE discovery of different kinds of mesons with rest-masses spreading over a considerable range has brought about a fundamental change in the aspect of the problem of elementary particles. It looks as if there exists a great many, possibly an infinite number of particles with different rest-masses, most of them being unstable, while a few have a long life-time. So long as one had to deal only with a small number of particles, the electron, nucleon (proton–neutron), and Yukawa's meson, it was appropriate to treat each of them separately and to describe them by wave equations constructed according to the more or less known properties (rest-mass, spin) of the particles. This procedure has now become inadequate; one has to face the problem of the inter-relation of the particles and in particular of their rest-masses. The safest course to take would, of course, be to wait until enough experimental material has been accumulated for building a reliable theory on it. Yet I think that preliminary work can be done now, namely, a discussion of the type of theory which could deal with the situation.

Each kind of particle is associated with a field (photon-Maxwell field, electron-Dirac field, meson-Yukawa field, etc.), satisfying a set of wave equations. Instead of these equations one can use the corresponding Lagrangian density L, the form of which depends on the spin, the rest-mass being the essential characteristic constant. If L is known, the field equations can be established; the solution of these are the wave functions ψ which determine the behaviour of the particles.

While the determination of ψ from a given L is the central problem of our present quantum mechanics, the new experimental situation demands a change of attitude: L itself becomes the unknown function. One needs, therefore, a general principle which determines the possible L's in regard to their spin-structure and rest-mass constant.

Some years ago, I suggested a very general principle, called the postulate of reciprocity, which states that the ultimate laws of physics should be symmetric in space-time x^k and momentum energy p_k ($k = 1, 2, 3, 4$). The evidence for this hypothesis is slender; it consists in the formal fact that this symmetry appears in the basic law of quantum mechanics, the commutation rule $x^k p_l - p_l x^k = i\hbar\delta_{kl}$, and in some other important concepts like the angular momentum. Further, many facts indicate the existence of a universal length a; then Planck's constant splits up into a product, $\hbar = ab$, where b is a universal momentum (or, for $c = 1$, an energy, or a mass). Finally, nuclear physics presents systems where neither a spatial description (allocation of positions to nucleons) nor a purely momental representation is adequate, but a combination of the two.

However, applied to present quantum mechanics (ψ-functions), this principle has not proved to be fertile. There is in Nature no obvious symmetry of the kind postulated. One has to go one step deeper and apply the postulate to the L-functions described above.

Before this could be done, a considerable amount of work had to be carried out in developing the most general field theories possible in such a way that the clumsiness of the usual formalism is avoided. This has been done by my collaborator, Dr. H. S. Green, who will explain his new methods of field quantization in another letter. Here a few points suffice.

Instead of the wave function ψ, there is used the statistical matrix ρ which for pure states reduces to $\psi\psi^*$ but represents also 'mixtures'. The most general Lagrangian of a field can then be written $L = F(p_k, p_k')\rho$, where F is a function of two sets of four variables; both these represent the momentum, but p_k operates on ρ from the left, p_k' from the right. Without going into details, it is only necessary to state Green's extremely simple result, that the field equations can be written in the form

$$F(p_k, p_k)\,\rho = 0. \tag{1}$$

Hence the function $(F p_k, p_k)$, or shortly $F(p)$, is characteristic of a given type of field.

I now propose to apply the principle of reciprocity to this function: only self-reciprocal functions F can be used for describing particles. This in combination with the principle of relativity is, in fact, a powerful instrument for obtaining particles with definite rest-masses. I shall indicate this for the example of scalar fields (spin zero).

A simple way of finding all self-reciprocal scalars is to determine the eigenfunctions of the operator $x^k x_k + p^k p_k$, where the co-ordinates and momenta are measured in the units a and b respectively ($ab = \hbar$). It is easy to see that the relativistic invariant eigenfunctions have the form

$$F(p) = f(P)\, e^{-P/2}, \tag{2}$$

where $f(P)$ are Laguerre polynomials of the argument $P = p_k p^k$. The simplest of these belonging to the eigenvalues 0, 1, 2 . . . are:

$$f_0 = 1, \quad f_1 = P - 2, \quad f_2 = P^2 - 6P + 6. \tag{3}$$

Since the exponential factor in (2) never vanishes, the field equations (1) reduce to

$$f(p)\rho = 0. \tag{4}$$

By factorizing the polynomial $f(p)$, one sees that (4) can be satisfied by plane waves with momentum-energy p^0_k if $P^0 = p^0_k p^{0k}$ is one of the roots of $f(x) = 0$. These roots are positive numbers easily obtained from (3); for example, for f_1, $x_1 = 2$; for f_2, $x_2^{(1)} = 3 + \sqrt{3}$, $x_2^{(2)} = 3 - \sqrt{3}$, etc. If x_r is one of these, one has a wave which satisfies

$$(p_k p^k - x_r)\,\psi = 0; \tag{5}$$

hence the conclusion suggests itself that $\sqrt{x_r}$ is a possible rest-mass.

To show this rigorously one has to investigate whether it is possible to formulate the quantized field theory for any such function in such a way that the total energy and momentum of the field appear in the form

$$P_k = \sum_r n_r p^0{}_k{}^{(r)}, \quad p^{0(r)}\, p^0{}_k{}^{(r)k} = x_r, \tag{6}$$

where the n_r are operators with integral eigenvalues. This has been proved for the most general Lagrangian by Green (see the following letter).

One has therefore already for scalar fields an infinite number of different particles with numerical rest-masses; the lowest are

$$\sqrt{2} = 1{\cdot}414, \quad \sqrt{3+\sqrt{3}} = 2{\cdot}175, \quad \sqrt{3-\sqrt{3}} = 1{\cdot}126, \ldots$$

and their ratios correspond roughly to some experimental results on mesons. But it would be premature to discuss this question.

Lagrangians for particles with spin can be found in a similar way. For example, for spin ½ one obtains, as the simplest self-reciprocal F, Dirac's expression with an exponential factor similar to that in (2).

One can regard the theory suggested here also from quite another angle, namely, as a rational generalization of relativity. Ordinary relativity is based on the invariance of the 4-dimensional distance, or its square $R = x^k x_k$. Can one really define distance of two particles in sub-atomic dimensions independently of their velocity ? This seems to me not evident at all.

The theory proposed here for scalar fields is equivalent to demanding as a fundamental invariant the sum $R + P = x^k x_k + p^k p_k$. For macroscopic bodies, where the p_k are extremely small in our units, this reduces to Einstein's $R = x^k x_k$; on the other hand, for the interior of nuclei, spatial dimensions are negligible and the generalized distance reduces to $P = p^k p_k$. In the general case the eigenvalues of $R + P$ are integers which indicate a kind of discontinuous structure of the x- or the p-space, while the eigenfunctions F determine the dynamical laws. For spin ½ one has to define the distance by taking the root of R and P with the help of properly chosen Dirac matrices.

It remains to consider the problem of interaction. So far as we can see at present, the postulate of reciprocity in conjunction with Green's field theory leads to a rational approach to this problem.

Whatever the success or failure of the special hypothesis suggested here, I am convinced that the quantum theory of particles has to solve the problem of determining Green's F-functions from some general principle.

MAX BORN

Department of Mathematical Physics,
University, Edinburgh.
Nov. 3.

Quantized Field Theories and the Principle of Reciprocity

THE quantum theory of wave fields (reviewed by Pauli[1] in 1941) shows it is possible, starting from a known Lagrangian function L, to calculate the charge-current vector, the energy-energy flux tensor, and the angular momentum tensor for any wave field, and further how to quantize the field in such a way that the charge, energy and momentum of the field are expressed as integral multiples of some elementary units which are associated with the constituent particles of the field. The theory has recently been extended by Chang[2] and de Wet[3] to a more general type of Lagrangian, involving any number of space and time derivatives of the wave vector; the calculations of these authors are, however, so complicated that it is difficult to see how they could be applied, even if any specific application were envisaged, and besides they do not fully satisfy the requirements of relativity.

There is now little doubt that the existence of mesons with several different masses requires a wave equation of the type

$$F(P)\psi = 0, \quad P = p_k p^k = E^2 - p^2, \tag{1}$$

where E is the energy operator $i\hbar\,\dfrac{\partial}{\partial t}$, and p the momentum operator $-i\hbar\,\dfrac{\partial}{\partial x}$, the masses of the different particles being obtained as the roots of the equation $F(m^2) = 0$. (In equation 1 and elsewhere, a repeated suffix (k) is summed from 1 to 4.)

As Prof. Born has proposed, the possible functions F may be determined uniquely by the principle of reciprocity. For the quantization of wave fields described by equations such as (1), the technique of field theory has to be considerably refined. A Lagrangian operator of the form

$$L = F(p_k, p_l')\rho, \quad p_k = i\hbar\,\frac{\partial}{\partial x^k}, \quad p_k' = -i\hbar\,\frac{\partial}{\partial x^{k'}} \tag{2}$$

may be defined, where ρ is the relativistic statistical operator, which is in the co-ordinate representation a function of two complete sets of co-ordinate variables $x^k \equiv (x,t)$ and $x^{k'}$. The operator ρ must be distinguished from the true density operator, to be defined later. The field equations, of which (1) is typical, are then

$$\left.\begin{aligned} F(p_k', p_l')\rho &= (F + \pi_k G^k)\,\rho = 0, \quad \pi_k = p_k' - p_k;\\ F(p_k, p_l)\rho &= (F + \pi_k' G^{k'})\,\rho = 0, \quad \pi_k' = p_k - p_k', \end{aligned}\right\} \tag{3}$$

which serve also to define G^k and $G^{k'}$. The equations of continuity, conservation of energy, energy transport, . . ., are obtained from them simply by multiplying the first by 1, p_k, $p_k p^k$, . . . , and the second by 1, p_k', $p_k' p^{k'}$, . . . , and subtracting, thus :

$$\begin{aligned} \pi_k(G^k + G^{k'})\rho &= 0,\\ \pi_k(F\delta_l^k - G^k p_l - G^{k'} p_l')\rho &= 0, \end{aligned} \tag{4}$$

where $R^k = \frac{1}{2}(G^k + G^{k'})\rho$ is interpreted as the density–flux vector, and $L_l^k = (F\delta_l^k - G^k p_l - G^{k'} p_l')\rho$ as the canonical energy flux tensor. It can be seen, therefore, that R^4 is the true density operator, and that the Hamiltonian energy-momentum vector

$$P_k = \int \tfrac{1}{2}(p_k + p_k')R^4 d\Omega \tag{5}$$

differs in the integrand from L_k^4 only by a space divergence which vanishes on integration over the real space Ω.

The commutation rule has the very simple form

$$\zeta_i R^4 \pm R^4 \zeta_i = \zeta_i, \tag{6}$$

where ζ_i is a creation operator for a particle with mass m_i, and the positive or negative sign is taken according as the particle obeys Fermi or Bose statistics. If ρ is expressed in the form

$$\rho = \sum_{ij} \psi_i(x_k)\,\psi_j^*(x_l'), \tag{7}$$

the rule (6) reduces to

$$\tfrac{1}{2}(G_4 + G_4')\,[\psi_i(x_k), \psi_j^*(x_l')] = \delta(x - x')\delta_{ij}\ (t' = t). \tag{8}$$

From this one can easily show that the field consists of particles with different but definite masses, to each of which can be assigned a definite energy and momentum. One can show further that the energy-momentum operator P_k has the property of the differential operator in commutation with ψ_i, so that the transition to quantum mechanics can now be completed by expressing the field equations in operational form.

This theory is quite general. When applied to Born's self-reciprocal Lagrangians, one obtains immediately the picture of a single quantized wave field in which particles with different rest-masses co-exist without interaction. Particles belonging to different

Birds in Britain

FRANCES PITT

This is the fourth book of the *In Britain* series. Miss Pitt has a genius for blending accurate description with pleasant reading, and in this book she covers the entire bird fauna of Britain. References to the part played by birds in literature are included, with many quotations. Illustrated. 25s. net.

A Text-Book of Heat

LeROY D. WELD, Ph.D., Sc.D.

This is an up-to-date text-book of heat and elementary thermodynamics of first-year university standard. It introduces the student to thermal phenomena and prepares him for subsequent studies in thermodynamics, meteorology, engineering, chemistry and other subjects. Attention has been devoted throughout to maintaining a consistent and appropriate physical and mathematical symbolism. 25s. net.

Modern Physics

G. E. M. JAUNCEY, D.Sc.

A comprehensive text, largely descriptive in character, suitable for degree students. A fair knowledge of physics and mathematics, including the elements of the calculus, is assumed. There is emphasis on topics of interest to physicists at the present time; thus this third edition includes a new chapter on nuclear fission. 33s. net.

Theory of Experimental Inference

C. WEST CHURCHMAN

This essay by the Assistant Professor of Philosophy at the University of Pennsylvania attempts to show that the methodology of science is no longer empirical and that the science of ethics is basic to the meaning of any question the experimental scientist raises. 21s. net.

RADIATION LABORATORY SERIES

Vol. 12

MICROWAVE ANTENNA THEORY AND DESIGN

Edited by Samuel Silver, Division of Electrical Engineering, University of California.

623 pages 9 × 6 48*s.* in U.K.

Provides a comprehensive survey of theory and design techniques for microwave antennas, and a full discussion of antenna measurement methods. A survey of those parts of electromagnetic and optical theory which are basic to the subject is followed by a series of chapters discussing various types of antenna feeds and the complete antenna systems used for producing all principal types of microwave beams. The aberrations and special features of microwave optical systems are discussed in relation to rapid scan antennas.

Vol. 18

VACUUM TUBE AMPLIFIERS

Edited by George E. Valley, Jr., Assistant Professor of Physics ; and Henry Wallman, Associate Professor of Mathematics, Massachusetts Institute of Technology.

733 pages 9 × 6 Illus. 60*s.* in U.K.

Seeks to analyse completely, to give design principles of, and to describe the special constructional techniques pertaining to many important types of amplifiers. The amplifiers selected for treatment are, in general, characterized either by very high gain, by large band-width, by great dynamic range, or by precise response. Following a theoretical introduction, video amplifiers, wide-band high-frequency bandpass amplifiers, low-frequency bandpass amplifiers, and direct-coupled amplifiers are discussed.

CHAMBERS'S SIX-FIGURE MATHEMATICAL TABLES

by

L. J. COMRIE, M.A., Ph.D.

W. & R. CHAMBERS, who in their long career as publishers of mathematical tables have produced such well-known compilations as Pryde's SEVEN-FIGURE MATHEMATICAL TABLES, Knott's FOUR-FIGURE TABLES, Chappell's FIVE-FIGURE TABLES, and Comrie's FOUR-FIGURE TABLES, have pleasure in announcing the publication of this very important new work. Dr. Comrie has brought to his task a lifetime's experience and an international reputation for table making and table typography. The result is a compilation completely adequate for all general purposes, everywhere interpolable with accuracy, and imposing no strain whatever on the eyes. Volume II contains an important Introduction on the use of tables with calculating machines.

VOLUME I—*Logarithmic Values*

Logarithms of Numbers, Antilogarithms.

Trigonometrical Functions in Degrees, Minutes, and Seconds.

Trigonometrical Functions in Degrees and Decimals, and in Radians (Circular Functions). Hyperbolic Functions. S and T Functions. Gamma Function, etc., etc.

eigenfunctions F may, however, interact directly, and it appears to be possible to determine the form of interaction uniquely from the principle of reciprocity, restricted only by the requirements of the conservation of charge, momentum and spin (angular momentum) which are consequences of the theory. It can therefore be hoped that the adoption of the principle of reciprocity may lead to a purely deductive theory of the sub-atomic particles in agreement with the experimental facts.

Low-Temperature Ultra-Violet Absorption Spectra of Biologically Important Compounds

The work of Holiday[1] on the ultra-violet absorption spectra of amino-acids at room temperatures, and of Caspersson[2] and others on the absorption characteristics of biological material, have made clear the importance of this physical approach to the greater understanding of the living cell. It has also been known for a long time that the absorption and fluorescence spectra of solids may sharpen as the temperature is lowered; in the inorganic field this effect has frequently been used in the interpretation of the energy states of ions. The work described in this note is the first step in an investigation of the possibilities of low-temperature microspectrography of biological material as an aid to distinguishing between various important compounds.

Since the work to be described was begun, Loofbourow[3] and others have given evidence concerning the narrowing of the ultra-violet absorption spectia of thymine and tryptophan. Below are given detailed results on the absorption spectra of some purines, pyrimidines and amino-acids at 90° K.

Absorption peaks of sublimed films

Compound	Absorption peaks at room temperature	Absorption peaks at 90° K.
Thymine	2827, 2763, 2709, 2653	2818, 2759, 2704, 2651, 2597, 2546
Uracil	2658, 2543	2859, 2796, 2723, 2650, 2558
Adenine	2868, 2764, 2663	2880, 2829, 2771, 2720, 2669
Guanine	2935, 2775, 2690	2918, 2830, 2774, 2719, 2666
Tryptophan	2998, 2880, 2810	2993, 2931, 2869, 2807, 2739, 2680
Phenylalanine	2693, 2655, 2593, 2535, 2482, 2427, 2222	2691, 2651, 2625, 2589, 2529, 2480, 2423, 2221, 2190

The low-temperature apparatus used was a glass-metal Dewar vessel, the inner metal portion of which consisted essentially of a 'fernico' tube closed at the lower end by a copper block. The 'fernico' alloy seals readily to glass, forming a seal which withstands the thermal strains set up by the cooling liquids used in the experiments. We are indebted to the director of research of the British Thomson-Houston Co., Ltd., for provision of the glass-metal seal. Cells suitable for the examination either of films, or of solutions that form glasses at low temperatures, can be readily interchanged. The cells were designed so as to screw directly into the copper block, which is immediately in contact with the cooling liquid. This apparatus may be used for studies as low as 60° K. The temperature of the specimens was measured by means of a contact thermocouple. With liquid nitrogen in the Dewar vessel, the temperature of films in the holder was 90° K.

A hydrogen discharge lamp was used as a source of continuous radiation, and films of purines, pyrimidines and amino-acids were prepared by sublimation under reduced pressure on to quartz coverslips. The infra-red spectra of films sublimed on to rock salt plates are practically identical with the results obtained from suspension of the same compounds in liquid paraffin. The ultra-violet absorption spectra were photographed in a Hilger medium quartz spectrograph, moving the photographic plate in its own plane by means of a logarithmic cam; this device, due to Holiday[4], shows up weak absorption bands to great advantage.

Figs. 2 and 4 show that although there is some structure in the absorption spectrum of uracil at 90° K., the sharpness of the thymine spectrum is much more marked. From a cytological point of view this difference holds interesting possibilities, since thymine is a constituent base of desoxyribosenucleic acid but not of ribosenucleic acid, and gives much sharper absorption peaks than the other bases (guanine, adenine, uracil) so far studied. These results, together with other work now in progress on tissue slices, indicate the importance of further ab-

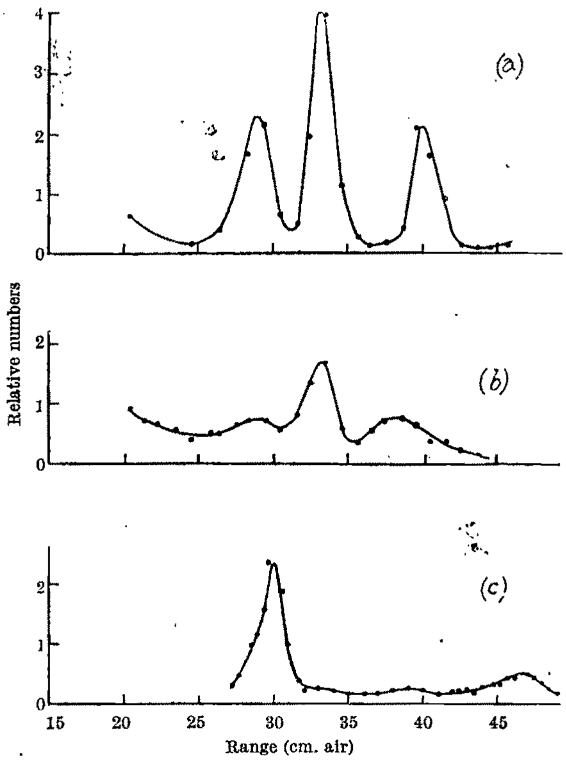
Disintegration of Separated Isotopes of Magnesium by Deuterons

IN a recent study of the transmutation of a number of elements by deuterons[1], the emission of three groups of protons from magnesium under deuteron bombardment was reported. These groups were assigned to particular isotopes by arguments based chiefly on the value of the energy released in similar reactions with other elements and on differences between the excitation functions of the groups. We have now been able to bombard separated isotopes, and the accompanying graph shows the proton groups observed from targets of magnesium-24, -25 and -26 deposited on stainless steel. The deuteron energy was 930 keV. as in the earlier experiments, and the protons were observed at right-angles to the incident beam. The three targets for which the results are shown in the figure were cut from larger areas on which the magnesium was deposited; but since the deposits were not uniform, the target thicknesses could not be accurately estimated. In the case of the magnesium-24 target, observation of the width of a ($p\gamma$) resonance-level suggested an equivalent thickness of about 10 keV.; the thickness of the magnesium-25 and -26 targets was unknown, and the relative intensities of the groups shown in the graph are therefore unlikely to be those which would be obtained from targets in the normal isotopic ratio of thickness.

The earlier interpretation of the proton groups now has to be revised and extended as follows:

Magnesium-24: The groups observed (Fig. *a*) are similar in range and relative intensity to those found from ordinary magnesium targets. The Q-value of 5·03 MeV. previously given[1] for the reaction $Mg^{24}(dp)Mg^{25}$ is therefore confirmed, and the other two groups shown in Fig. *a* indicate excited states in magnesium-25 at 0·58 and 0·98 MeV.

Magnesium-25: We believe that the groups observed (Fig. *b*) from this target are due to contamination by magnesium-24, since they are the same both in range and relative intensity, within the limits of error of the experiment, as those observed from the magnesium-24 target. This has been established by careful counting, under conditions of good geometry and low bias, for several different magnesium-25 targets. There is no evidence for the previous assignment of the 35-cm. proton group to the transmutation $Mg^{25}(dp)Mg^{26*}$, although a small group of this range from magnesium-25 would be obscured by the contamination groups from magnesium-24. The main reason for originally ascribing the 35-cm. group to the transmutation of magnesium-25 was the fact that its excitation function differed strikingly from that of the 32- and 42-cm. groups[1]. Two of us (C. A. W. and C. D. C., unpublished) have since shown that this difference may be explained by variations in the angular distribution of the emitted particles with bombarding energy.



Number-range curves for protons emitted in the bombardment of targets of separated isotopes of magnesium by deuterons: (*a*) Mg^{24}; (*b*) Mg^{25}; (*c*) Mg^{26}. The target thicknesses do not necessarily correspond to the normal isotopic ratio

Magnesium-26: The group of protons of range 32 cm. (Fig. *c*) found from the separated target would not have been resolved in the experiments with ordinary magnesium from the strong group of similar range from magnesium-24. The new group gives a Q-value of $4·21 \pm 0·1$ MeV. for the reaction $Mg^{26}(dp)Mg^{27}$ instead of the value previously quoted of 4·05 MeV. The group of protons at 48 cm. appears on blank targets and could be due to carbon contamination.

The separated targets have also been used to confirm the reaction $Mg^{26}(d\alpha)Na^{24}$ [1]. The 15-hr. activity of sodium-24 was easily observed and followed from the magnesium-26 target after deuteron bombardment, while the activity of this period from similarly bombarded targets of magnesium-24 and -25 was at least ten times smaller.

We are very grateful to Sir John Cockcroft and to Dr. W. D. Allen and members of his group at the Atomic Energy Research Establishment, Harwell, who provided the separated targets used in this work.

Magnetic Moments of Deuterium-2, Lithium-7 and Fluorine-19

THE exceptionally small natural line-widths obtainable with the magnetic resonance absorption method[1,2] or nuclear induction method[3,4] makes these methods suitable for precision measurements of nuclear magnetic moments. We have constructed an apparatus for this purpose, and have paid special attention to the problem of getting a magnetic field which fulfils the rather extreme requirements of field homogeneity. In this case it was also important that the homogeneity was of such an extension that two different probes could be investigated at the same time on two different places in the field. The pole-pieces of the magnet were 30 cm. in diameter, separated by spacers 4·2 cm. apart. Both the pole-pieces and the spacers were polished optically flat, so that the air gap was the same within 1 μ everywhere.

For the detection of the resonances we have used the balance method first proposed and used by Purcell, Torrey and Pound[1]. The field was carefully mapped by inserting a water probe in the field and observing the difference in resonance frequency for protons in different places. We have been able to find two extremely homogeneous places in the field where resonance absorption simultaneously can be studied, one for protons and the other for the unknown magnetic moment. The homogeneity was such that the line-widths in the two places were about 0·1 gauss. The very small difference in magnetic field between the two places (2 in 10^6) was determined by observing simultaneously the proton resonances in both places.

The signals from the two high-frequency bridges were fed to a double-beam oscillograph, and the two frequencies were adjusted to get the two signals to coincide. Any displacement between the signals on the screen was corrected for by photographing the screen. The total amplitude of sweep on the screen usually corresponded to about 0·3 gauss and was synchronized with the modulation of the magnetic field.

Every magnetic moment has been measured several times at different field-strengths. The two frequencies to be compared were measured by a General Radio Frequency Standard (Type 1100-*A*, form 664-*A*), which permits an accuracy of 1 in 10^6 in the frequency determination. Our determinations of the nuclear magnetic moments of D^2, Li^7 and F^{19} are summarized in Tables 1, 2 and 3 (the diamagnetic correction is not included).

All moments are expressed in the proton moment as a unit. For deuterium-2 we obtained $\mu_D/\mu_P =$ 0·3070183 ± 0·0000015; for lithium-7 $\mu_{Li^7}/\mu_P \doteq$ 1·165833 ± 0·000050; and for fluorine-19 $\mu_{F^{19}}/\mu_P =$ 0·940934 ± 0·000015.

All our individual measured values fall inside the limits given here. Only the deuteron moment has been determined before by this method, and our value agrees within the limits of error with the determination by Bitter *et al.*[5] ($\mu_D/\mu_P =$ 0·307021 ± 0·000005), but falls a little outside the value obtained by Bloch *et al.*[6] (0·3070126 ± 0·0000020).

The μ-values of lithium-7 and fluorine-19 have not previously been measured accurately by the new method. The values obtained with Rabi's method[7] (μ_{Li^7}/μ_P = 1·16622 ± 0·00090 and $\mu_{F^{19}}/\mu_P$ = 0·9410 ± 0·0013) are given with considerably higher limits of error, but are consistent with our new values.

A more detailed report of this work will appear in *Arkiv för Mat., Ast., och Fysik.* This investigation has been sponsored by the Swedish Natural Science Research Council.

Slow-Neutron Capture in Helium

THE cross-section for capture of thermal neutrons in helium according to the reaction

$$He^3 + n \rightarrow H^3 + p + 750 \text{ keV}.$$

has been measured relative to the similar reaction in nitrogen for which the cross-section is given as 1·7 barns[1]:

$$N^{14} + n \rightarrow C^{14} + p + 600 \text{ keV}.$$

Cloud-chamber photographs of the helium reaction by slow neutrons have recently been obtained by Hughes and Eggler[2], who found an energy release of 740 keV. The cross-section for such a reaction might be expected to be large.

Briefly, the method was to compare the counting-rates produced in a gridded ionization chamber filled alternately with atmospheric helium, containing 1·20 × 10^{-6} parts[3] of helium-3, and argon, containing a small known admixture of nitrogen, irradiated in a thermal neutron flux of approximately

10^5 neutrons/cm.^{2}/sec. at the thermal column of the Harwell low-energy pile (G.L.E.E.P.).

The helium used contained 2 per cent of nitrogen, which was removed by passing the gas over a large quantity of activated absorption charcoal. British Oxygen Co. 'oxygen-free' argon was used, containing about 0·3 per cent of nitrogen.

Counts were taken on a differential pulse-height analyser, and a well-resolved energy peak was obtained in each case. In order to eliminate effects due to fast neutron recoils in the abundant helium-4, counts were taken with and without cadmium surrounding the chamber in the helium runs. Counts with cadmium in the argon runs were negligible.

If N_1 is the total counting-rate due to the thermal (n,p) reaction in helium, and N_2 the total counting-rate due to the reaction in nitrogen present in the argon, then, under otherwise identical conditions,

$$\frac{N_1}{N_2} = \frac{\sigma_1 p_1 C_1}{2\sigma_2 p_2 C_2},$$

where σ_1 is the cross-section for the He^3 reaction, p_1 is the total pressure of helium in the chamber, C_1 is the concentration of helium-3 in atmospheric helium; while the corresponding quantities with subscript 2 refer to the N^{14} reaction in the argon, and the factor 2 allows for the fact that nitrogen is diatomic.

The ratio N_1/N_2 in a single such measurement could be obtained to an accuracy of about 2 per cent, the pressures p_1 and p_2 were measured on a calibrated pressure gauge, and the nitrogen content C_2 was known to about 6 per cent from mass spectrometer measurements and has been checked by other means. p_1 was made approximately four times p_2 in order that the proton ranges should be roughly equal in the two fillings.

From several separate determinations, a mean value for the cross-section was found to be

$$\sigma_{\mathrm{He}^3} = (3{,}700 \pm 250) \times 10^{-24} \text{ cm.}^2.$$

This figure is given relative to 1·7 barns for the cross-section of N^{14} and $1{\cdot}20 \times 10^{-6}$ for the helium-3 content of atmospheric helium.

It is believed that all nitrogen was removed from the helium in these experiments, and indeed mass spectrometer measurements have set an upper limit of 10^{-4} parts to the nitrogen content. If this amount were, in fact, present, the above cross-section would be too high by some 6 per cent, which is within the error of the measurement.

In conclusion, we wish to thank Prof. F. E. Simon of the Clarendon Laboratory for lending us a cylinder of atmospheric helium, and Mr. G. H. Palmer for making the mass spectrometer analyses.

A complete account of this work will be given later.

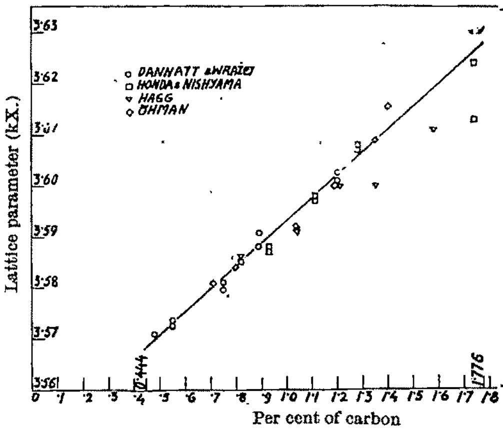
Lattice Spacing of Retained Austenite in Iron–Carbon Alloys

IT is generally accepted that the lattice parameter of retained austenite in quenched iron–carbon alloys increases continuously and linearly with the increase of carbon content. So far, however, the presence of retained austenite has only been recognized when the iron–carbon alloy contains more than 0·6 per cent of carbon[1].

The assumption put forward by me[2] that the gamma solid solution in iron–carbon alloys is composed of pseudo-phases called γG, γS, γE, the amounts of which depend on the carbon content of the particular alloy, makes it possible to assume the existence of retained austenite in quenched alloys containing even less than 0·6 but more than 0·444 per cent of carbon. The examination of alloys in this composition range justifies the assumption.

An accurate measurement, for example, by means of the combined substance method[3] applied to X-ray films, taken from various iron–carbon alloys in quenched condition, confirms the continuous change of spacing of retained austenite to the extent that its regularity enables the determination of the carbon content of a particular alloy to be made.



% C.	kX.
1·776	3·6281
1·70	3·6245
1·60	3·6200
1·50	3·6155
1·40	3·6110
1·30	3·6065
1·20	3·6020
1·10	3·5975
1·00	3·5930
0·90	3·5885
0·80	3·5840
0·70	3·5795
0·60	3·5750
0·50	3·5705
0·444	3·5678

The accompanying graph shows the lattice spacings of retained austenite in iron–carbon alloys determined by various authors[1], including our own measurements[4]. The data shown, and many others collected during the experiments, suggest that there must be a theoretical value of lattice parameter for retained austenite in each of the quenched iron–carbon alloys containing carbon between 0·444 and 1·776 per cent. The most probable values of these can be represented by the straight line, and calculated from the formula:

$$a_\gamma = 3{\cdot}5678 + 0{\cdot}045\,(C - 0{\cdot}44) \text{ in kX.},$$

where 3·5678 in kX. is the most probable spacing of retained austenite in an iron–carbon alloy with 0·444 per cent of carbon, 0·045 is the value of the tangential function, that is, the constant increase in lattice parameter (0·0045 kX.) for 0·1 per cent of carbon, and C is the percentage of carbon in the alloy.

The figures thus obtained for the lattice spacing of retained austenite in a given iron–carbon alloy after quenching make it possible to decide that the measurement of the X-ray film was correct and that the heat-treatment was properly performed.

More detailed data connected with the description of the heat-treated iron–carbon alloys will be published elsewhere.

Deviation at Vertical Incidence in the Ionosphere

It was pointed out by Booker[1] ten years ago that even at vertical incidence the ordinary and extraordinary rays are deviated in the ionosphere, an effect that may be explained by the change in direction of the associated Poynting vectors. They are deviated in opposite directions from the vertical in the earth's magnetic meridian plane, and at their reflexion points they make angles with the vertical of D and $\tan^{-1}[\sin 2D/(3 - \cos 2D)]$, respectively, where D is the angle that the earth's field makes with the horizontal.

The latter deviation has a maximum value of 19° 28′ when $D = 35° 16′$; but under conditions when the earth's field is within, say, 30° of the vertical, the horizontal distance between the ordinary and extraordinary reflexion points can be as much as 50 km. for the F layer for frequencies close to the ordinary critical frequency. It follows that at times when large horizontal gradients exist in the ionosphere, the electron densities at the reflexion points for the ordinary and extraordinary critical frequencies can be markedly different.

Little mention of this possibility has so far been made in connexion with ionospheric sounding, but it appears that the effect can be large enough to influence the detailed interpretation of vertical incidence records. The deviation of the rays by the magnetic field, and by the horizontal gradient itself, may have an appreciable effect on the separation of the ordinary and extraordinary critical frequencies, and may account in part for the occasions when it differs markedly from its normal value. Alternatively, caution must be exercised, when using the separation as a measure of the gyro-frequency, in interpreting such variations as due to changes in the value of the earth's magnetic field.

In conclusion, we may remark in connexion with ionospheric observations made during an eclipse, when marked horizontal gradients of density must occur near the edges of the totality belt, that this effect may be of significance both with regard to the optimum siting of the sounding station, and to the conclusions drawn concerning the density changes caused by the eclipse.

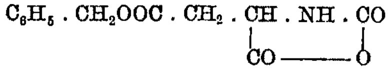
Synthesis of Poly-Aspartic Acid

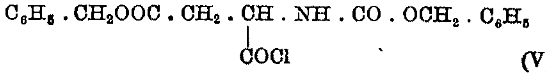
In previous publications we have reported on the polymerization of representatives of normal[1] and of basic[2] α-amino-acids. In the present communication the synthesis of poly-aspartic acid is dealt with as an example of the polymerization of a trifunctional acidic α-amino-acid.

A suitable monomer was found in the N-carboxy anhydride of *l*-aspartic acid β-benzyl ester,



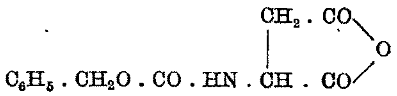
$$\begin{array}{l} C_6H_5\,.\,CH_2OOC\,.\,CH_2\,.\,CH\,.\,NH\,.\,CO \\ \qquad\qquad\qquad\qquad\quad | \qquad\qquad\;\; | \\ \qquad\qquad\qquad\qquad\; CO\text{———}O \end{array} \quad (I)$$

The reversible masking of the β-carboxyl group by the benzyl ester group ensures the exclusive participation of the α-carboxyl group of the aspartic acid in the peptide linking of the monomeric units. The monomer was obtained in the following way. The di-silver salt of N-carbobenzoxy *l*-aspartic acid (II)[3] gave with benzyl iodide in ether N-carbobenzoxy *l*-aspartic acid dibenzyl ester (III); partial hydrolysis by the calculated amount of potassium hydroxide in benzyl alcoholic solution affected the benzyl group attached to the α-carboxyl group only, and yielded the N-carbobenzoxy aspartic acid β-monobenzyl ester (IV). On suitable treatment of the latter with phosphorus pentachloride, the monomer I was obtained. The intermediate chloride (V)



$$\begin{array}{l} C_6H_5\,.\,CH_2OOC\,.\,CH_2\,.\,CH\,.\,NH\,.\,CO\,.\,OCH_2\,.\,C_6H_5 \\ \qquad\qquad\qquad\qquad\quad | \\ \qquad\qquad\qquad\qquad\; COCl \end{array} \quad (V)$$

was not isolated. The results of elementary analysis are consistent with formula I, but do not exclude the isomeric N-carbobenzoxy aspartic acid anhydride (VI)[4],

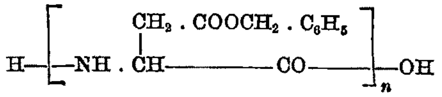


(VI)

the formation of which is also conceivable from (V) on loss of benzylchloride.

Some of the facts which prove that the substance obtained is different from (VI) and correctly represented by formula I are as follow: (i) the melting point found (111°, with evolution of carbon dioxide) is different from that of (VI) (124°)[4], and is depressed by the admixture of a preparation[4] of the latter; (ii) the ninhydrin colour reaction is positive; (iii) on heating, evolution of gas occurred, the loss of weight being in agreement with the calculated value of one mole carbon dioxide per mole of (I); the polymer obtained has the elementary composition to be anticipated in using a monomer of the formula I, and gives a strong biuret reaction.

In accordance with previous experience[2], monomer I was carefully dried in the polymerization vessel in high vacuum, first at room temperature and then at 60°, prior to the polymerization, which was carried out in high vacuum with stepwise raising of the temperature. At 109°, melting occurred with strong evolution of gas, causing a definite increase in pressure. On its decrease, the temperature was raised to 125° and the heating continued until evolution of gas appeared to have ceased entirely. The solid reaction product, giving a strong biuret reaction, is, according to analytical data, the poly-aspartic acid β-benzyl ester (VII):



$$H-\left[-NH\,.\,\overset{\displaystyle CH_2\,.\,COOCH_2\,.\,C_6H_5}{\overset{|}{CH}}\text{————}CO\text{———}\right]_n-OH \quad (VII)$$

Van Slyke amino-nitrogen (manometric) determinations gave values of maximal 0·07 per cent amino-nitrogen, indicating an average chain-length of at least a hundred units and a molecular weight average of at least 20,000.

The corresponding poly-aspartic acid was obtained by treatment of a solution of the poly-ester (VII) in glacial acetic acid with phosphonium iodide in a stream of hydrogen gas. It is slightly soluble in hot water, soluble in dilute alkali.

We found that careful treatment of the poly-aspartic acid ester with normal alkali does not affect the peptide linkages; it appeared, therefore, feasible to obtain the acidic poly-α-amino-acids by eliminating suitably chosen (β- or γ-) ester groups from the respective poly-esters through hydrolysis with dilute alkali instead of the hydrolysis of these (benzyl) ester groups by phosphonium iodide. Experiments on these lines were started some time ago but were interrupted by conditions here.

A polymeric substance, the properties of which suggest peptide structure, was obtained from the product of the reaction of thionyl chloride on N-carbobenzoxy-*l*-aspartic acid (II). On heating this reaction product to 165°, melting occurred with evolution of gas and formation of a glassy mass which gave a positive biuret reaction, a negative reaction for diketopiperazines, and yielded the theoretical amount of aspartic acid on hydrolysis.

On prolonged heating of *l*-aspartic acid at 200° according to Schiff[5], a fraction not mentioned by him, insoluble in hot water, was obtained, giving a positive biuret reaction and having about 1 per cent of its total nitrogen in the form of amino-nitrogen. Hydrolysis of this product leads quantitatively to free aspartic acid. The structure of this polymer has not yet been clarified.

The experiments reported here are part of an investigation (cf. the thesis of one of us (A. B.) for the M.Sc. degree of this University) carried out in 1947. The conditions prevailing in Jerusalem during the present year [1948] have delayed the conclusion of this work.

Photosensitization by Vat Dyes

IT is well known that cellulose fabrics dyed with certain vat dyes disintegrate on exposure to light[1]. The experimental evidence suggests that a photosensitized oxidation of the cellulose is responsible. It is known that dyes do, in fact, photosensitize a number of reactions[2]; but no systematic survey of the field has been attempted, and the factors which determine the relative efficiencies of different dyes are not known. In a preliminary study of photosensitization, we have found that such dyes can initiate the autoxidation of tetralin, and the polymerization of styrene.

A tungsten filament projection lamp (1 kW.) was used as light source in the polymerization experiments, and a hot mercury arc (350 W.) in the autoxidation. In the latter case the light was filtered through 1 cm. of a 10 per cent solution of ferric alum in 2*N* sulphuric acid to remove light of wave-length less than 3600 A. The rates of reaction relative to pure tetralin and pure styrene are given in Table 1. The figures are approximate only, since many of the dyes fade, especially during the polymerization.

Table 1

Dye	Relative rate of oxidation $pO_2 = 650$ mm. $T = 25°$	Relative rate of polymerization $T = 14°$
Caledon Yellow 5*G*	25	26
Cibanone Yellow *R*	17·8	18·8
Cibanone Orange *R*	10·5	15·5
Cibanone Yellow 2*GR*	7·7	11·4
Caledon Golden Yellow *GK*	5·3	—
Cibanone Orange 6*R*	4·9	6·7
Caledon Red *BN*	2·4	9·5
Caledon Dark Blue *G*	1·2	20·0
Caledon Jade Green *XN*	1·0	5·5
Caledon Jade Green 2*G*	0·9	7·9
Caledon Orange 2*RT*	0·8	—
Caledon Gold Orange 3*G*	0·6	—
Caledon Dark Brown 2*G*	0·1	14·0

In Table 1 the dyes are arranged in order of activity for the autoxidation. This is closely similar to that for the 'tendering' activities of the dyes on cellulosic materials[3]. Both reactions probably have a common origin, namely, the formation of radicals by removal of hydrogen atoms from the substrate by the excited dye. The relative activities in the photopolymerization are not in the same order, and presumably a different mechanism is involved, for example, a direct transfer of energy.

In the case of the autoxidation the general mechanism seems to be established (see following communication), and it is possible to determine the quantum efficiency of the primary process. The following approximate values have been determined for $\lambda = 4500$ A.

Table 2

Dye	Quantum efficiency for sensitization ($pO_2 = 100$ mm.)
Caledon Golden Yellow *GK*	0·0053
Anthanthrone	0·012
Caledon Red *BN*	0·0021

Comparison with Table 1 shows that for the most active dyes the quantum efficiencies must be very high—close to unity.

We anticipate that photosensitization by dyes may have wide applications, and we are at present engaged in their study.

Absolute Velocity Constants in the Autoxidation of Tetralin

THE main features of the autoxidation of unsaturated hydrocarbons have been established by Bolland and Gee[1]. The autoxidation of tetralin probably follows a similar course, although the published work[2] is open to criticism. If the kinetic scheme of Bolland and Gee is accepted, dye photosensitization offers a convenient method of determining the velocity constants absolutely. In our programme of work on absolute velocity constants[3], we have therefore studied the sensitized oxidation of tetralin.

This reaction presents experimental difficulties, since it must be studied at oxygen pressures much lower than those used by Bolland. Under these conditions, the rate of solution of oxygen is not sufficient to keep the liquid saturated. Although allowance can be made for this effect in the steady-state kinetics, it is impracticable to determine the life-time of the chains by standard methods, for example, the rotating sector[4]. Moreover, the reaction has an appreciable rate in the dark, even at 25°. In order to determine the absolute velocity constants, it is therefore necessary to obtain alternative relations between the constants to replace those normally derived from the life-time. By following the reaction in a Warburg-type apparatus, and by applying appropriate corrections, we have been able to measure the true photochemical after-effect. We have established that this is due to the finite life of the chains, and is independent of the initiation step; it therefore provides the required relations. It is also necessary to know the absolute rate of chain starting. This was measured by a standard inhibitor method, the validity of which we have proved in this case.

The steady-state kinetics are consistent with the scheme:

$$\begin{array}{llll} D + h\nu \rightarrow D^* & I_{\mathrm{abs}} & T\mathrm{O}_2 + TH \rightarrow T\mathrm{O}_2H + T & k_4 \\ D^* \rightarrow D & k_f & 2T \rightarrow ? & k_5 \\ D^* + \mathrm{O}_2 \rightarrow D + \mathrm{O}_2 & k_1 & T + T\mathrm{O}_2 \rightarrow ? & k_6 \quad (1) \\ D^* + TH \rightarrow DH + T & k_2 & 2T\mathrm{O}_2 \rightarrow ? & k_7 \\ T + \mathrm{O}_2 \rightarrow T\mathrm{O}_2 & k_3 & & \end{array}$$

in which D, TH represent dye and tetralin respectively. For long chains, with the approximation[1] $k_6 = \sqrt{k_5 k_7}$, this leads to

$$-\frac{d[\mathrm{O}_2]}{dt} = \left\{\frac{k_2 I_{\mathrm{abs}} [TH]}{k_f + k_1[\mathrm{O}_2]_l + k_2 [TH]}\right\}^{1/2} \frac{k_3 k_4 [\mathrm{O}_2]_l [TH]}{k_3 \sqrt{k_7} [\mathrm{O}_2]_l + k_4 \sqrt{k_5} [TH]}, \qquad (2)$$

where $[\mathrm{O}_2]_l$ is the concentration of oxygen in the liquid. The term in the first bracket on the right of (2) gives the rate of chain-starting; it will be noticed that at high oxygen pressures the excited dye is de-activated by oxygen. We intend to study this reaction in more detail. The after-effect, $\Delta[\mathrm{O}_2]$, is given by

$$\Delta[\mathrm{O}_2] = \frac{k_3 k_4 [\mathrm{O}_2]_l [TH] \{k_3[\mathrm{O}_2]_l + k_4[TH]\}}{\{k_3 \sqrt{k_7} [\mathrm{O}_2]_l + k_4 \sqrt{k_5} [TH]\}^2} \log \tfrac{1}{2} (1 + \xi), \qquad (3)$$

where ξ is the ratio of the photochemical and thermal rates. If the reaction has no thermal rate, an analogous expression for $\Delta\mathrm{O}_2$ may readily be deduced, but it is more convenient to provide a 'thermal' rate by continuous weak illumination.

Since the rate of chain-starting is known, equations (2) and (3) each provide two relations between the velocity constants k_3, k_4, k_5, k_7. The values obtained for these constants at 25° were $k_3 = 6{\cdot}8 \times 10^7$, $k_4 = 13{\cdot}3$, $k_5 = 7{\cdot}1 \times 10^6$, $k_7 = 2{\cdot}2 \times 10^7$ litre mol.$^{-1}$ sec.$^{-1}$. From the variation of rate with temperature, the following differences of activation energies were found:

$$\begin{aligned} E_4 - \tfrac{1}{2}E_7 &= 4{\cdot}3 \text{ kcal.} \\ E_3 - \tfrac{1}{2}E_5 &= -1{\cdot}5 \text{ kcal.} \end{aligned} \qquad (4)$$

From the temperature coefficient of the after-effect at high oxygen pressures, E_4 was found to be 4·2 kcal. Unfortunately, the results at low oxygen pressures were not sufficiently accurate to allow E_3 and E_5 to be determined separately. However, it is unlikely that E_5 is appreciably greater than 2·8 kcal., the value for the termination reaction between similar radicals in the polymerization of styrene[3], and from (4) it cannot be less than 3 kcal.

The following table summarizes these conclusions. Activation energies are probably correct to 1 kcal.

$E_3 = 0$ kcal.	$A_3 = 6{\cdot}8 \times 10^7$
$E_4 = 4{\cdot}3$,,	$A_4 = 1{\cdot}8 \times 10^4$
$E_5 = 3{\cdot}0$,,	$A_5 = 1{\cdot}1 \times 10^9$
$E_7 = 0$,,	$A_7 = 2{\cdot}2 \times 10^7$

Quantitative Paper Chromatography

Fisher, Parsons and Morrison[1] have shown experimentally that a linear relation holds between the area of the spot of test substance and the logarithm of the concentration at which it is originally applied. A theoretical derivation can now be given.

If it be supposed that the spot spreads by diffusion as it moves along the chromatogram, analogous equations developed in the theory of heat-flow may be applied. For a spot initially at concentration c_i over a circle of radius a, the appropriate equation[2] is:

$$c = \frac{c_i}{2Dt} \cdot \exp\left(\frac{-r^2}{4Dt}\right) \cdot \int_0^a \exp\left(\frac{-r'^2}{4Dt}\right) \times I_0\left(\frac{rr'}{2Dt}\right) \cdot r' \cdot dr',$$

where c is the concentration at radius r at time t, and D is a diffusion constant. Putting F for the integral containing the modified Bessel function, remembering that $r^2/4Dt$ equals $A/4\pi Dt$, where A is the area of the spot, and taking c as the concentration at the limit of visibility, that is, at the edge of the spot, we can take logarithms (to base 10) and rearrange equation 1 to become:

$$A = \frac{4\pi Dt}{\log e}\,[\log c_i - \log c - \log (2Dt) + \log F], \quad (2)$$

which only differs from the experimental relation found by Fisher *et al.* by the term log F; c and Dt are constant for the same substance in the same chromatogram.

Values of log F were computed graphically in the region of $2Dt$ from 0·02 to 1·50 sq. cm., a from 0·1 to 1·0 cm., and r from 0·1 to 2·0 cm. It was found that a further re-arrangement could be made so that direct use of the simple plotting of A against log c_i was possible. Log F increases as A increases. Replacing log F by $(k.A + B + f)$, where k is a proportionality factor, B is the value of log F when r is zero, and f is the deviation from proportionality, and noting that B equals $\log 2Dt + \log [1 - \exp(-a^2/4Dt)]$, we can write:

$$A = \frac{4\pi Dt}{\log e - 4\pi Dt\,.\,k}$$

$$\left[\log c_i - \log c + \log\left\{1 - \exp\left(\frac{-a^2}{4Dt}\right)\right\} + f\right]. \quad (3)$$

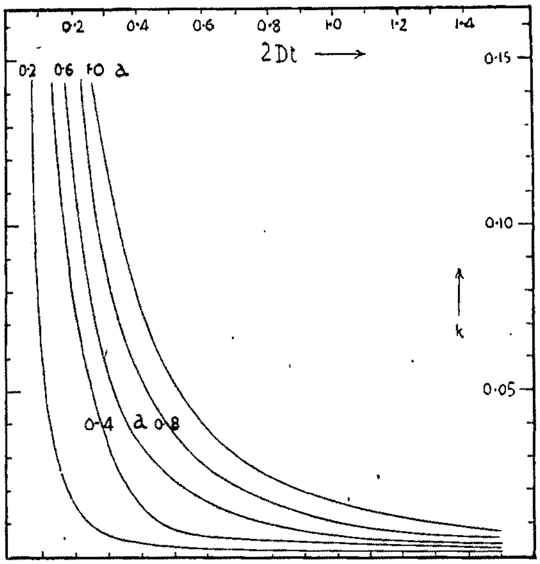
Values of k and f were computed by drawing a straight line to the plots of log F against A (up to A equals 7·0 sq. cm.), so that the maximum deviations positively and negatively were equal. The graph shows values of k. The table (from which the accuracy of the computations may be judged) shows the deviation calculated as a percentage; thus a percentage of 1·0 corresponds to the value 0·00432 (log 1·01) of f, and may be considered as equivalent to an error in the determination of c_i from the plot of A against log c_i.

Percentage deviation

		a (cm.)				
		0·2	0·4	0·6	0·8	1·0
$2Dt$ (sq. cm.)	1·50	0·1	0·4	0·5	0·4	0·3
	1·00	0·3	0·5	0·3	0·3	0·3
	0·75	0·6	0·1	0·3	0·6	0·6
	0·50	0·5	0·5	0·6	0·7	1·7
	0·40	1·2	1·2	1·0	1·9	3·3
	0·25	1·2	1·0	4·7	6·0	7·1
	0·10	6·0	15·0	23·0	7·5	—

The necessity of attaining the higher values of $2Dt$ in experimental work is clear, as is the importance of keeping the initial area of the spots small and uniform.

A practical example may now be considered. By measuring the areas of the spots in the diagrams of the communication of Fisher *et al.*[1] and relating them to the quoted length of 34 cm., the values of the arbitrary units of area may be estimated roughly, and the slope of their lines for the three amino-acids appears to be about 4 sq. cm. From equation 3, the slope S, that is, the factor outside the square brackets, gives $2Dt = 0{\cdot}0691\,.\,S/(1 + k\,.\,S)$. Thus, the value of $2Dt$ for their data cannot be greater than 0·28 (their a values are not given), and their expected error of 2 per cent in the determination of an unknown concentration (c_i) can be realized provided that the value of a is less than 0·4.



An obvious way of improving the accuracy is to run the chromatogram for a longer time, thereby increasing the magnitude of $2Dt$.

I am grateful to Mr. A. J. Ede for helpful criticism and advice.

Location of Paper Chromatogram Spots of Purine and Pyrimidine Derivatives in Ultra-Violet Light

THE methods so far described in the literature for the identification of spots of purines, pyrimidines and their derivatives on paper chromatograms are unsatisfactory. We have found a simple and rapid method for their detection.

If the paper strip run with n-butanol as described by Hotchkiss[1] is examined in ultra-violet light transmitted by a Wood's glass or Corning 5970 filter (320–400 mμ) the spots are not visible, though the position of the butanol front is conspicuous as a fluorescent band. Light transmitted by a Corning 9863 filter (230–400 mμ), however, shows the spots as dark patches against the background of paper fluorescence, either by reflected or transmitted light. The most suitable light source was found to be a low-pressure mercury resonance lamp, and further experiments with various filters showed that the intensity in the region of the 254 mμ line was the important factor. The dark patches are probably due to the strong absorption of the radiation which excites the paper fluorescence; their boundaries are readily marked by a pencil so that they can be cut out and eluted for spectrophotometric estimation. The spots are visible down to concentrations of the order of 0·5–1·0 μgm./cm.[2].

The effect has been observed with adenine, adenosine, uracyl, uridine, thymine, cytidine, hypoxanthine, xanthine and various methylated xanthines.

*Nor*adrenaline in Adrenal Medullary Tumours

BLASCHKO[1] has suggested the stages by which adrenaline can arise from tyrosine, the final stage being the N-methylation of the primary amine *nor*adrenaline. It is possible that this last stage occurs in the suprarenal medulla; but hitherto *nor*adrenaline has not been found in the normal suprarenal gland.

A portion of human suprarenal tumour was kindly sent to this laboratory by Dr. E. G. Hall. Histological examination by Dr. P. Glees showed that the tumour was a typical phæochromocytoma consisting of chromaffin tissue. An acid extract of the tumour was prepared and tested for adrenaline and *nor*adrenaline. The rat's uterus and the frog's perfused heart were used in order to determine the adrenaline content of the extract, since these preparations are insensitive to *nor*adrenaline[2]. It was found that 1 ml. extract was equivalent to 0·37 mgm. adrenaline.

When tested on the rabbit's duodenum and the spinal cat's blood pressure, which are approximately equally sensitive to adrenaline and *nor*adrenaline, the extract was found to be equivalent to 1 mgm. adrenaline per ml. The difference between the activities found on these two types of preparations may be assumed to be due to *nor*adrenaline. Thus 1 gm. tumour contained 3·7 mgm. *l*-adrenaline and 6·3 mgm. *l*-*nor*adrenaline. The presence of both amines was confirmed by tests with polyphenolase which were carried out by Dr. W. O. James. When the enzyme was incubated with tumour extract, a brown colour, typical of *nor*adrenaline, was produced during 10 min. This colour faded, and after 20 min. a rose-pink colour, typical of adrenaline, appeared. This reaction was also given by a mixture of the synthetic amines and is specific for them. James[3] has described a method of separating adrenaline and *nor*adrenaline by paper chromatography. Phenol is used as a solvent, and after 20 hours the positions of the two amines are determined by the pink colour produced by them when the paper is sprayed with potassium ferricyanide solution. The tumour extract gave two spots at positions typical of adrenaline and *nor*adrenaline.

Two other adrenal medullary tumours were also examined. One was sent by Dr. G. M. Wilson from St. Mary's Hospital; 1 gm. of this tumour was found to contain 5·3 mgm. *l*-*nor*adrenaline and 0·32 mgm. *l*-adrenaline. The other was sent by Dr. A. M. Joekes from the British Postgraduate Medical School, and 1 gm. contained 5·5 mgm. *l*-*nor*adrenaline and 0·37 mgm. *l*-adrenaline. These results were obtained from assays against both *l*-adrenaline and *dl*-*nor*adrenaline on the rat's uterus and rabbit's duodenum.

Since *nor*adrenaline has slightly greater pressor activity than adrenaline, it is probable that the attacks of high blood pressure caused by the tumours were mainly due to *nor*adrenaline.

Gelatination of Blood Serum with Fibrinogen

WHILE much research work is focused on the complex mechanism of biological blood coagulation, comparatively little attention has been paid to the action of fibrinogen on blood serum. Whereas the action of the complete activator system leads with blood-plasma to a relatively firm coagel in a matter of seconds, the action of pure fibrinogen on blood serum leads to an elastic coagel only after two or three hours. This coagel remains transparent, and as there is no apparent sign of coagulation of fibrinogen, we prefer the term 'gelatination'.

The fibrinogen (human) was prepared after the method of Astrup and Darling[1] and was up to 96 per cent clottable. We measured the action on normal blood serum (human), on blood serum and plasma after treatment with barium sulphate (Rosenfield and Tuft[2]) and on a 5 per cent solution of albumin (crystalline, bovine). The mixtures with varying amounts of fibrinogen wore in small test tubes at 18° C. The volume in each case is 1·2 ml.

Fibrinogen added (mgm. per cent)	Serum (human)		Barium sulphate serum		Albumin 5 per cent	
	3 hr.	24 hr.	3 hr.	24 hr.	3 hr.	24 hr.
15	++	++	+	++	–	+
30	+++	+++	++	+++	–	++
60	+++	+++	++	+++	–	+++
120	++	+++	+	+++	–	+++
180	+	+++	+	+++	–	+++

+, Marked increase in viscosity; ++, partial gelatination; +++, tube can be reversed without spilling

When 120 mgm. per cent of fibrinogen is added, gelatination of serum is complete after two to three hours, in serum treated with barium sulphate after six hours and in 5 per cent albumin only after eighteen hours. It seems that serum globulins accelerate the process but are not absolutely necessary. No gelatination takes place in oxalated blood plasma after threefold Seitz-filtration (Owren)[3] or after treatment with barium sulphate.

In order to discover the influence of nucleic acids on gelatination, serum solutions of yeast nucleic acid[4] ($C_{38}H_{49}O_{29}N_{15}P_4$), adenosine-3-phosphoric acid ($C_{10}H_{14}N_5O_7P + H_2O$), adenosine triphosphate ($C_{10}H_{12}O_{13}P_3Na_4$) and thymonucleic acid with a molecular weight of approximately a million were tested in two series: (*a*) concentration of fibrinogen 30 mgm. per cent, and of nucleic acids 917 mgm. per cent; (*b*) 120 and 666 mgm. per cent respectively.

Series	Yeast nucleic acid			Adenosine-3-phosphoric acid			Adenosine triphosphate			Thymonucleic acid		
	3 hr.	7 hr.	24 hr.	3 hr.	7 hr.	24 hr.	3 hr.	7 hr.	24 hr.	3 hr.	7 hr.	24 hr.
a	+	++	++	–	–	–	–	+	+	+	+	++
b	+++	+++	+++	–	–	–	–	+	++	++	++	+++

It follows that yeast nucleic acid as well as thymonucleic acid only slow down the process of gelatination, whereas adenosine-3-phosphoric acid inhibits it. With this latter substance the clotting time of fibrinogen by thrombin is twenty times as long as with yeast nucleic acid[4].

The adenosine-3-phosphoric acid was provided by Messrs. Hoffmann–La Roche and Co., Basle.

Action of 'Blood-Group Substances' on the Anti-Ken Serum

SINCE the publication of our previous communication[1], we have continued our investigations with the anti-Ken serum, but after adding Witebsky's 'purified blood-group substances', supplied by the courtesy of Sharp and Dohme, Philadelphia.

Testing 248 unselected bloods with the original serum gave the following results[1]:

	+	−
A cells	46	45
O cells	102	55

Testing 300 unselected bloods with the 'absorbed anti-Ken' serum gave a different distribution:

	+	−
A cells	77	73
O cells	76	74

We do not find in our new series tested with the 'absorbed' serum the difference observed previously when using the original serum; but, on the contrary, there is an even ratio of about 50 per cent + and 50 per cent − reactions in both *O*- and *A*-groups. This ratio was actually the one found in the *A*-cell group when using the original serum.

Thus the addition of 'blood-group substances' seems to inhibit the constituent of the original serum responsible for the agglutination of some 15 per cent of extra-bloods in the *O* cell group. This indicates that the original serum contains two antibodies.

Unfortunately, our stock of the original anti-Ken had come to an end when we realized this fact. The patient was bled, but the agglutinin(s) had disappeared from her serum. We are now attempting to get an immune reaction by inoculating her with small amounts of Ken + blood.

Priority in the recognition of the phenomenon we have described should go to R. R. Race[2], when absorbing Andresen's[3] anti-L_2 with the *A* blood-group substance prepared by W. T. J. Morgan. There is, indeed, a close similarity between L_2 and Ken: the positive and negative reactions of anti-L_2 and anti-Ken are distributed similarly with a difference between *O*- and *A*-cell groups; on the other hand, both sera behave in the same way when in contact with 'blood-group substances'.

'Brassy' Eosinophilic Granulocytes and their Possible Role in Iron Transport

IN blood films stained by one of the Romanowsky modifications, the granules of the eosinophiles are ordinarily scarlet. Occasionally, however, they exhibit a range of colour modification which varies from brownish-red, through grey to almost coal-black. The latter granules are not to be confused with those of the basophilic granulocyte, which have also been found in otherwise unaltered 'eosinophiles' in autochthonous hyperheparinæmias; truly basophilic granules are metachromatic when stained with toluidine blue, while the dark granules of the 'brassy' eosinophiles (as such cells have come to be termed in laboratory parlance) are not basophilic nor do they stain with toluidine blue. The appearance of the 'brassy' granule does not seem to be a staining artefact, as they appear preponderantly in the blood films of certain individuals even though these blood films have been subjected to identical and concurrent staining procedure with films exhibiting the scarlet eosinophilic granule.

The probable nature of the 'brassy' granule was disclosed inadvertently in another connexion. A patient with megaloblastic anæmia was given parenteral liver extract therapy and made a good response with the usual reticulocytosis, increase in blood cholinesterase and eosinophilia, but the anæmia shifted to a hypochromic type. The latter phase was then treated with ferrous lactobionate solution given intravenously. On one occasion, when it was desired to make a routine blood study (to save the patient an additional venipuncture), blood was aspirated directly into the syringe from which the iron solution had just been expressed. The smear from this blood showed all eosinophiles to be of the 'brassy' type. The addition of small quantities of ferrous salts to blood samples was found to convert the ordinary eosinophilic granule to the 'brassy' form. That this form may represent an iron conjugate of the eosinophilic granule is a possibility that might open the additional possibility that the eosinophile is concerned in some phase of iron transport.

Amino-Acid Constitution of Diphtheria Toxin and Toxoid

WHILE examining by two-dimensional paper partition chromatography the acid hydrolysates of highly purified diphtheria toxin and toxoid, preparatory to attempting the quantitative estimation of the constituent amino-acids by the method of Woiwod[1,2], a striking qualitative difference has been observed between the chromatograms of these two substances, which we feel may be significant.

The photograph of a typical chromatogram of the hydrolysate of toxin is given in Fig. 1, while that of toxoid is shown in Fig. 2. It will be seen that tyrosine is present in the toxin but not in the toxoid hydrolysate. No other major differences have been observed between the chromatograms.

The highly purified diphtheria toxin and toxoid used in this work were prepared by the method of Pope and Linggood (unpublished), and both preparations contained 2,100–2,200 Lfs./mgm. protein nitro-

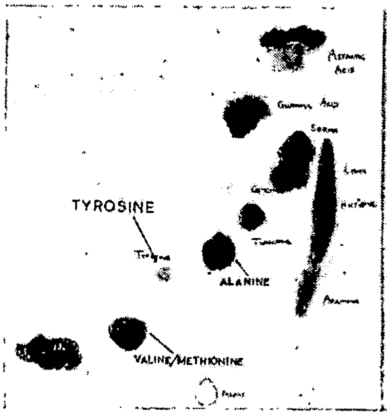

Fig. 1

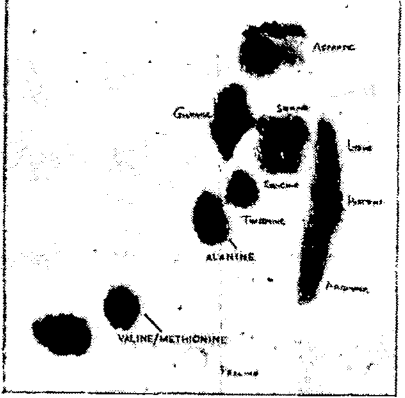

Fig. 2

gen, but were somewhat less pure in terms of Lfs./mgm. total nitrogen. The non-protein nitrogen was eliminated from both preparations by precipitation and washing with trichloroacetic acid (5 per cent) prior to hydrolysis of the protein with 6*N* hydrochloric acid for 72 hours.

Samples of the hydrolysates containing approximately 200 µgm. of nitrogen were used for the preparation of the two-dimensional chromatograms, which were run first with *n*-butanol-acetic acid and then with phenol.

Holden and Freeman[3], and also Brown[4], have shown that formaldehyde reacts with tyrosine under alkaline conditions to give a product stable to acid hydrolysis, devoid of amino-nitrogen and negative to the ninhydrin test. Therefore, a possible explanation of our observations is that the amino-group in the tyrosine present in diphtheria toxin is not involved in a peptide linkage, but is free to combine with formaldehyde during the process of 'toxoiding'. This is not, however, the only explanation for the apparent lack of tyrosine in the hydrolysed toxoid, and we are engaged in further work to find the actual mechanism involved. This will be published in detail later.

Microbiological Oxidation of Sterols

In an earlier communication[1] we stated that by cultivating *Proactinomyces roseus* in a synthetic culture medium in which the only source of carbon and nitrogen was 2 per mille pyridine, and using up the superfluous nitrogen by emulsifying 0·1 per cent cholesterol in the medium and aerating it at 34° C., in two weeks we obtained 7-oxycholesterol and 4,5-cholestenone. Later, we received a letter from Dr. G. A. D. Haslewood, of the Physiological Laboratory, Guy's Hospital, London, S.E., expressing doubt that the occurrence of 7-oxycholesterol was the result of the microbiological oxidation; in his opinion, the result was analogous to the production of 7-oxycholesterol from cholesterol in alkali medium, by aeration and elevated temperature, as shown by Bergström and Wintersteiner[2,3], in which case the micro-organism plays no part.

We have now carried out further experiments. In a synthetic culture medium at *p*H 7, *Proactinomyces* previously cultivated in a 2 per mille pyridine solution decomposes the pyridine into ammonia at 34° C. without special aeration, besides incorporating part of the nitrogen into itself. After complete destruction of the pyridine, the *p*H of the culture rises to 7·5. We then add 0·1 per cent cholesterol to the culture and again 2 per mille pyridine. At the same time we begin aeration at 34° C. Two weeks before extraction of the substances, we determined the *p*H of the cultures and found the average value to be 8·2–8·4.

Control experiments were carried out by regulating the same synthetic pyridine culture medium with ammonia to the minimum *p*H of 7·5 in one control, and in the other to the maximum *p*H value obtained at the end of the culture, that is, 8·2–8·4, and, on adding cholesterol, aerated it under the same conditions as in our chief experiment. In the control experiments we never obtained 7-oxycholesterol at these *p*H values. In a special series of experiments without micro-organisms in the synthetic pyridine culture medium described we found that, with aeration at 34° C., we obtained 7-oxycholesterol only at the outside values of 11–11·5 *p*H, and then only traces.

We must, therefore, repeat that, in the experiments originally reported[1], the 7-oxycholesterol was produced as an effect of the activity of the micro-organism.

Complement Fixation Test in Contagious Ecthyma

During both research and routine complement fixation tests with foot-and-mouth disease virus, we attempted to develop a similar test for the condition known as contagious ecthyma of the lips, infectious or contagious pustular dermatitis or stomatitis and infectious labial dermatitis. The observations clearly indicate that this condition has an extensive geographical distribution.

The technique used was similar to that described by Aramburu[1] for complement fixation test in foot-and-mouth disease. The antigen was made from desiccated crusts from sheep infected experimentally with the virus. The scabs were thoroughly triturated with sand, suspended in 1 in 10 saline and centrifuged 10 min. at 2,500 r.p.m.; the supernatant fluid, containing the antigen, could be preserved for at least fifteen days at – 20° C. Sera were obtained both thirty-one and eight days after infection, centrifuged 15 min. at 3,000 r.p.m. and inactivated 45 min. at ~ 56° C. In our experiments the control tubes included the three types of foot-and-mouth disease sera, guinea pig normal serum, and both ovine and human normal serum.

Although only eighteen tests were made, all gave positive results, thus demonstrating both the specificity of the test in this condition and the appearance of complement-fixing antibodies in sheep serum. A typical result (Protocol No. 270) is given herewith.

Tube	Antigen	Serum	Saline	Complement	Red cells	Minutes reading		
						10	20	30
1	0·25	0·05	0·25	0·25	0·5	++++	++++	++++
2	0·25	0·05	0·25	0·25	0·5	++++	++++	++++
3	0·25	0·05	0·25	0·25	0·5	++++	++++	++++

Further experiments with regard to its specificity will be published in due course.

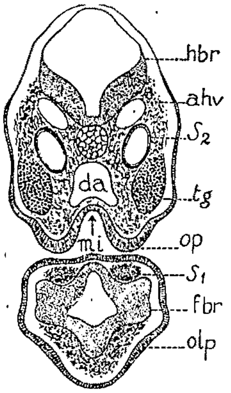
The 'Oral Placode' in Certain Selachii and its Bearing on the Origin of the Vertebrate Mouth

IN the course of a study of the early development of the sensory placodes of the head region in some cartilaginous fishes from the Red Sea, namely, *Carcharinus melanopterus* (Quoy and Gaimard), *Rhynchobatus djiddensis* (Bloch and Scheider) and *Rhinobatus halaui* (Müller and Henle), it was found that in the embryos of length 5–10 mm., the epidermis is generally thickened on either side of the roof of the mouth invagination and in the neighbourhood of the hypophysis (see drawing). This ectodermal thickening is of the same structure as the epibranchial placodes which, in these embryonic stages, are situated at the dorsal edges of the corresponding branchial slits. In view of its particular situation over the mouth, it should be regarded as homonymous with these epibranchial placodes and as belonging to them. The structure in question should then have the same relation with the oral slit as the epibranchial placodes have with the spiracle and the following gill-slits. The term 'oral placode' was suggested for this structure, which is thus interpreted as providing an interesting confirmation and adding further evidence to Dohrn's[1] well-known and much discussed[2] theory considering the mouth of vertebrates as derived from a pair of anterior coalesced gill-slits.



Transverse section through the mouth region of a 9·5-mm. embryo of *Rhynchobatus djiddensis* illustrating the relation of the oral placode and the mouth

ahv, anterior head vein; *da*, dorsal aorta; *fbr*, fore-brain; *hbr*, hind-brain; *mi*, mouth invagination; *olp*, olfactory placode; S_1, first head somite (Platts' mass); S_2, second head somite; *tg*, trigeminal ganglion

Shadow Area of Convex Bodies

VOUK[1], in a letter in *Nature*, gave a proof of Cauchy's theorem that the average area of projection of a convex body on a plane equals one-quarter the surface area of the body. The following less formal version of the proof may appeal more to non-mathematicians.

The projected area of a sphere equals the area of a circle of the same radius, that is, $\pi \times (\text{radius})^2$. The surface area is $4\pi \times (\text{radius})^2$. Hence, Cauchy's result is true for a sphere. Because of the symmetry of a sphere, the result must be true of each infinitesimal element of the sphere's surface, that is, any infinitesimal element of area considered in all its possible orientations has an average projected area equal to one quarter of its own area. Now the surface of any convex body consists of a number of such infinitesimal areas; hence by adding the separate contributions from each we obtain Cauchy's theorem. As pointed out by Vouk[1], if the assumption of convexity were not made, the above value of shadow area will be too large, because the contributions of certain surface elements in certain orientations will be nullified by obscuration.

Bilateral Asymmetry shown by the Metachronal Waves in Protochordate Gill Slits

BECAUSE of delay in correcting and returning proofs, the letter under this title in *Nature* of January 22, p. 137, contains an error in the last paragraph. The larvæ of Enteropneusta rotate in an anti-clockwise direction viewed from the animal pole, *not* a clockwise one. To judge from the literature there cited and from a later reference to the subject by van Wijhe[1], the hatching larvæ of *Amphioxus*[2], which are remarkably similar in general appearance to *Saccoglossus* larvæ, rotate consistently in the same direction and swim in a similar manner.

PROBLEMS OF OLD AGE

THE medical, social and economic problems created by a rapidly ageing population were the subject of a symposium presented before a joint session of Sections I (Physiology) and J (Psychology) at the British Association meeting at Brighton on Friday, September 10, 1948.

The subject was introduced by Sir Ernest Rock Carling, who reminded his audience that the great majority of the elderly are healthy and independent —they outnumber the ailing and decrepit by more than 30 to 1—and for them the most pressing problem is how to maintain to the end of their days the standard of living of their working life. The time has come for the elderly to revolt against the convention, based on sociological, not biological, grounds, that there is a fixed retirement-age beyond which they are unfit for further work. It is a truism that chronological age is no guide to capacity in the individual; but what we want to know is, how far the increased expectation of life in the last fifty years has extended working-capacity. Although at sixty to-day we have only a matter of months more to expect than those of that age fifty years ago, nevertheless a far greater number are reaching the sixth and seventh decades, presumably because they have been less subject in early and middle life to diseases which have come largely under control.

Ageing begins at birth, and an athlete is 'old' at thirty-five. Yet what is 'old'? There have been few controlled researches into the causes or processes of ageing. Over the whole range of function we need the help of physiologists to measure such modification as age brings. In war they extended the functional powers of young men to a remarkable extent; by similar study they will certainly be able to suggest optimum conditions for maximum accomplishment when functions are modified or restricted by age. Just as in war combat-stress had to be allowed for, so in peace the stresses inherent in the job may be too great to be easily borne as the years pass: adaptations of work for the elderly must extend to psychological as well as physical demands.

Recent work among the derelict 'chronic sick' has shown remarkable recuperative powers among those thought to be past remedial treatment. If such efforts can restore lost powers, those powers should never have been lost; and continuance in some occupation should be, and is, a sound recommendation for the prolongation of life and happiness. Given some inducement and suitable conditions, the country can draw upon a proportion of the elderly for productive work. For the young disabled there exist workshops where, with special appliances, and adaptations of machines—and a deal of encouragement—selected jobs are accomplished.

Laziness, Sir Ernest maintained, is at the bottom of much facile acceptance of 'too old at forty, fifty, or sixty'. If the Civil servant must retire, why does not the clergyman? If the barrister ceases to practise, why not the judge?

The small percentage of the elderly whose health or social circumstances deteriorate have been in the past scurvily treated. For them the 'institution' must be replaced by small homes, graded to suit the phases of ageing and grouped to enable the residents to pass from semi-independence to full communal care without too much apparent change in surroundings. If local authorities and voluntary bodies co-operate—as they can under the National Assistance Act—it should be possible to throw off the damning inheritance of the 'workhouse' stigma that hangs about public endeavour and the 'charity' that, at least in the prejudices of some local politicians, taints private ventures. Though the proportion of old people badly needing such help may be small, the task of providing for them is enormous, for some two or three thousand homes are needed.

Dr. Marjory Warren followed with a description of her own pioneer geriatric unit at the West Middlesex County Hospital. She maintained that the tendency to lay emphasis on *cure* rather than *care* may be in part responsible for the lack of interest and industry with the so-called incurables. More than 80 per cent of the old people admitted to hospital are suffering from pathological, physiological or psychological conditions which fall under two headings, medical and social. The medical conditions are: degenerative arterial disease, degenerative heart disease, arthritis, malignant diseases, and progressive neurological diseases. The social conditions are lack of hygiene, help, food and company. A service of gerontology is needed which will integrate medical and social care. In addition to domestic and social care, such a service requires three types of accommodation: a geriatric unit based on a general hospital, a long-stay annexe for the truly irremediable, and hostels of various kinds for those reasonably fit who have no suitable home of their own. Medically, all three should be under the same supervision, because the lines between sickness and infirmity, and infirmity and health, become finer as years advance. Yet new legislation now divides the authorities for medical treatment and social care of the elderly.

Dr. Warren described the present position as chaotic and uneconomic. A very large number of remediable old people lie at home under inadequate care and no treatment, unable to get a bed in hospital. In hospitals there are elderly ambulant patients, no longer needing hospital care, for whom no hostel vacancies exist; and in hostels will be found sick old people without access to treatment.

The present writer attempted to set the old-age problem in the context of the larger problem of European population trends, which have social, economic and strategic implications for Western civilization. The population of Europe, having grown enormously—and in relation to world population—in the last three hundred years, has now reached maturity and faces relative decline. To-day it is the non-European populations that are growing fast, with declining death-rates and high birth-rates. North-western Europe—headed by France, once the most populous and now the most 'aged' nation—has led the process, and is destined to contract relatively to eastern Europe, and in particular to the U.S.S.R. Russia, because of late development, is relatively young; and this has a possible strategic significance. It has been estimated that, if present trends continue, another twenty or twenty-five years will see a decrease of nearly 5,000,000 in the man-power of military age in Europe west of U.S.S.R., and, an increase of more than 13,000,000 in Russia's military man-power. There is a shift in the balance of man-power from west to east.

The static, perhaps soon declining, populations of western Europe are ageing populations, and their working populations are ageing and declining. This means that for youngsters it is easier to start work, but harder to advance, since there are fewer opportunities at the top. The difficulty of individual advancement encourages solidarity among workers, accompanied by growing pressure in favour of early retirement—blindly regardless of the fact that the retired have to be maintained from the product of the reduced labour force. The increasing social burden substitutes group responsibility for individual or family responsibility, and the enterprising initiative of an expanding economy is replaced by a longing for the security of an ordered economy. Thus there is created the 'problem of old age'.

In the United Kingdom the present percentage of old people in the population is double what it was in 1901, and treble what it was in 1881—just a life-time ago. It will go on increasing until, in the life-time of many now living, old people will equal or outnumber the children, and the total proportion of dependants (children and old people) to workers will increase from the present 54 per cent to 62 per cent. Only technological progress and increasing productivity will be able to keep pace with this growing social burden.

If the prospect for Britain, and Europe, appears gloomy—with our dwindling man-power and the growing predominance of other cultures—we have to remember that it was Western civilization which, in its vigorous youth, showed the world how to overcome poverty, famine and disease, and so how to release the brake upon population growth. It has yet to be proved that there is any compulsory connexion between social and animal biology, or that an ageing population means a senile body politic.

Mr. A. T. Welford described the tentative results of some experiments, in the Psychological Laboratory at Cambridge, in measuring the achievement of different age-groups at realistic and fairly complex tasks involving motor and mental skill. The first task—throwing chains at a target, first direct, then over a bar, and then with target screened and seen only in a mirror—revealed little difference in accuracy from the 'teens to the sixties until the target was screened, when accuracy fell steadily with age (and the over-thirties tended to look for the chains to throw while the youngsters kept their eyes on the mirror). In the second task the subjects were required to move a pointer on a piece of graph-paper until it corresponded with a small stationary ball on another piece alongside; if successful, the ball had to be started moving and then to be stopped in a new position, and the cycle began again. At this task there was a slightly better total achievement by the under-thirties; but the older subjects' much slower, more deliberate, and also more accurate performance might in a sense be judged more efficient.

In mental skills two experiments were described which required the comprehension and organisation of data. First, in drawing conclusions from a set of logically connected statements, older people tended to treat the statements as real, and to talk about them rather than deduce from them. In the second 'mental' experiment the subjects were required to deduce, by meter-readings, the correspondence between a circuit-diagram and a box with terminals connected underneath by resistances. Here the older age-groups needed to take more readings, some more than once, which indicates their greater difficulty in organising the data and perhaps the beginnings of a loss of short-term memory. In conclusion, Mr. Welford stressed the tentativeness of all these interpretations, but suggested that an important locus of change with age lay in the manner of organising data or comprehending a display.

Mrs. Barbara Lewis dealt with one aspect of the economic consequences of an ageing population, namely, the employment of older workers. Since such employment may become an economic necessity, it needs to be examined from both the old people's and the employers' points of view. Are old people willing to work, and is their work economic? Like all recent investigators, Mrs. Lewis was able to confirm, from her Birmingham survey of the over-seventies, the therapeutic value of continued occupation: that women live longer than men is undoubtedly influenced by men's tendency to retire with a jolt at a fixed age, while women suffer no such sharp break. Though some men look forward to freedom to pursue hobbies and interests, there is a difference between the social and occupational groups: clerks and managers usually relish the prospect of retirement but are deterred by the certainty of a much lower standard of living, whereas manual workers frequently complain of boredom in the retirement into which they have been tempted by the smaller gap between earnings and pension.

The old people available and able for employment fall into three groups: those preferring and intending to work as long as possible; those failing or tired, who look forward to ceasing work as soon as they are financially able to retire; and those less definite about retirement, who could be swayed by a pension scheme offering greater inducements (than does the National Insurance Act, 1946) to postpone retirement or by special conditions of work if they continue.

From the employers' point of view, it is generally only when loss of efficiency and the need for transference to lighter work arises that there is formal consideration of an employee's age and capacity. (On the staff side it is different, and strictly enforced retiring-ages are common, to preserve reasonable prospects of promotion.) There is no difficulty about retaining skilled craftsmen, even when pace and output fall off; but the unskilled or semi-skilled factory worker, who may, especially in heavy trades, lose efficiency with increasing years, is not so easy to retain, since alternative lighter work may be difficult or impossible to arrange. Even where old men could successfully undertake work normally done by women or boys, the trade unions' insistence on the minimum adult man's rate makes old men too expensive to use. Even if two old men could be paid only half a younger man's rate to reach the younger man's output, the costs of production will still be higher, since the administrative costs per worker have to be taken into account. On the other hand, older workers have many recommendations: they are normally more conscientious and better time-keepers, have greater respect for rules and the employer's property, and generally mind their jobs more carefully, knowing that other work will be hard to find.

As a consequence of an ageing population, industry will have to adjust itself to a labour force with a higher proportion of older workers. This may involve more mechanization and the further elimination of heavy exertion, possibly some special conditions for elderly workers, and certainly a considerable amount of research and job-analysis to reveal the types of work most suited to the employment of older workers. Mrs. Lewis concluded the symposium with the cheerful reflexion that, in encouraging old people to remain as long as possible in employment, the best interests of the nation and the aged coincide.

In the discussion that followed, it was clear that some lay members of the public, at least, are more interested in the causes of ageing and in the search for some partial elixir of life than in the more serious problems raised for society by a rapidly ageing population. W. A. SANDERSON

NEW BUILDING MATERIALS

THE widespread incidence of the shortage of houses justifies even a belated account of a discussion on "Building Materials with Special Reference to New Materials", held in Section B (Chemistry) of the British Association on September 14. The full text of the four main papers read at the discussion has already been published*.

Speaking on "Some Modern Trends in Building Materials", Dr. F. M. Lea, director of building research, Department of Scientific and Industrial Research, described the factors which influence both the development of new materials and new methods and their assimilation into the traditional structure of the building industry—developments which have made it essential to study building scientifically with the object of reshaping its traditions to modern needs. The potential demand for building materials is so large that the industry offers an attractive field for exploitation of newly discovered materials and a prospective outlet for industrial by-products. To be successful, a new material must be suitable in all needful respects for the purpose for which it is intended, and must be capable of being used without major change in existing craft processes. Large manufacturing resources and ample supplies of raw materials are essential if a new product is to become generally used. The industry can readily absorb new materials introduced on a relatively small scale, and these, if they prove to meet a real need, can be commercially successful and lead to the establishment of major industries, as has happened, for example, with asbestos-cement products, concrete roofing-tiles and fibre boards. Increased stress on functional requirements—thermal insulation, sound insulation and so on—leads to consideration of how the technical needs can be met by materials singly or in combination with others. This stimulates the development of new materials or new ways of using them. Changes must of necessity be slow because new materials and new techniques have to be grafted on to an established body of practice by a widely scattered labour force.

Dealing with "The Use of Aluminium Alloys in Building", Mr. E. I. Brimelow, of the Chief Scientific Adviser's Division, Ministry of Works, described the rapid growth of the aluminium industry which has brought aluminium and its alloys to the status of engineering materials in little more than a century. The strength of aluminium alloys compares favourably with that of mild steel; the lower modulus of elasticity can be allowed for by appropriate increase in the dimensions of structural members without undue increase in weight. The relatively low melting point need cause no anxiety about the fire-resistance of loaded members; it is necessary only to provide a thicker covering for insulation and fire protection to obtain a performance comparable with that of steel. The low density of aluminium and its versatility of form fit it for use as a decorative material, as window-frames and rain-water goods, and, with due discrimination, for plumbing. It is used for spray coatings and as scaffolding. The low emissivity of clean, bright aluminium foil allows it to be used in cavity types of construction as an insulating material. Though generally resistant to corrosion, some precautions are necessary in the use and maintenance of aluminium and its alloys. Anodizing affords useful protection and gives a good surface for painting, which is recommended for rain-water goods in industrial and coastal districts. The good appearance of aluminium window-frames can be maintained by regular washing with water or by polishing with wax. In plumbing applications, electrolytic corrosion can be avoided by appropriate choice of the associated materials and by use of insulating washers. Use of aluminium for hot- and cold-water supply installations will not be advisable until the cause of a pitting type of corrosion which occurs in some districts has been further studied. The aluminium bungalow, using aluminium in combination with foamed-concrete insulation, has made a substantial contribution to the temporary-housing programme. With some improvements, the method of construction is being extended to provide permanent houses, schools and factories. Shortage of building materials has given opportunity for trial of those new uses for aluminium which could be technically justified, and the experience so gained will be a valuable guide for the future. The advent of cheaper methods of production would increase its potentialities.

Dr. T. W. Parker, of the Building Research Station, dealt with "Light-weight Building Materials", development of which has been fostered by present demands for thermal efficiency arising from the desire to achieve economy in fuel consumption and to provide increased comfort for the occupants. Low-density blocks can be used as load-bearing materials; sheet materials form linings or cladding; fibrous or granular materials are used as 'loose fill' or as blankets or 'bats'. Light-weight blocks, besides having a substantial insulating value, have the merit of high thermal capacity, the importance of which is often overlooked. Its influence in smoothing out variations in temperature is particularly valuable where intermittent methods of heating are installed. The greatest advance among low-density materials has been in the development of cellular concrete, which can be made in a number of different ways with a density of 20 lb. per cu. ft. upwards. Except in the aluminium bungalow, this material has not yet been used to any great extent in Great Britain, but experience in Sweden has demonstrated its potentialities. Light-weight sheets used as wall linings provide thermal insulation and offer a surface that can be quickly warmed to a comfortable temperature. Such materials must be robust enough to withstand accidental damage. They must not introduce an additional fire hazard. When circumstances preclude the use of low-density boards, the desired thermal resistance can be attained by using stronger boards fixed with an air space behind them. 'Loose fills', blankets and 'bats' form a convenient form of insulation for hollow walls and for roofs and ceilings. They must be chemically and physically stable, and should not give off noxious or combustible gases in the event of fire. They are mostly made from glass-wool, slag-wool or mineral-wool. Production of vermiculite in South Africa has stimulated interest in expanded vermiculite for use as 'loose fill', as concrete aggregate, and as a constituent of insulating plaster applied by spraying. Its cost is at present higher than that of other forms of insulation.

* *The Builder*, 175, 335, 365, 393, 454 (1948).

Speaking on "The Use of Plastics in Building", Mr. R. J. Schaffer, of the Building Research Station, stressed the importance of selecting the building (and all other) applications of plastics with due regard to their suitability for the purpose intended. The idea of using plastics, other than resin-bonded wood, as load-bearing members is no longer of practical interest. Thermoplastics are obviously unsuitable for such use; the low modulus of elasticity, lack of ductility and high cost make it impracticable to use thermo-setting plastics. The advent of synthetic, waterproof glues has increased the potentialities of plywood and of glued construction in timber, and has led to the development of new kinds of building-board made from wood-waste or other by-products. Plastics enter into the composition of a variety of flooring materials. Polyethylene, already used for piping beer, etc., promises to be useful for domestic cold-water supply and sanitary installations. Foamed or 'expanded' plastics may be used for thermal insulation. There is a wide scope for the use of moulded plastics as building fittings; adoption of the British Standards Institution certification mark will ensure that high standards of design and workmanship are maintained. R. J. SCHAFFER

THE NUFFIELD FOUNDATION

THE third report of the trustees of the Nuffield Foundation*, which includes a list of 'fellows' appointed during the year, the balance sheet and a schedule of grants, records an allocation of grants during the year ended March 31, 1948, amounting to £495,350, the largest of any year up to date. The grants allocated since 1943 now total £2,135,980; this includes £605,850 to medical sciences; £242,000 to natural sciences; £142,000 to social sciences; £509,900 (including £225,000 over fifteen years to the Dominion Students' Hall Trust for the development of London House) for fellowships and scholarships; and £589,700 (of which £500,000 is to the National Corporation for the Care of Old People) for the care and comfort of the aged poor. During 1947, the resources of the Trust have been enriched by a gift of £450,000 from Capt. Oliver Bird. This benefaction, to be known as the Oliver Bird Fund, is to be held on trust for promoting research into the prevention and cure of rheumatism or, failing that, for the advancement of health and relief of other sickness. The trustees are now turning their attention to the planning of the programme for the next quinquennium, and they point out that the welcome increase of State support for learning and research does not lessen the need for voluntary enterprise or decrease the importance of alternative sources of support if the principle—fundamental to a free and democratic society—is to be upheld that "there should be room for more than one opinion and for more than one means of putting that opinion to the test".

A new grant in the medical sciences of £50,000, payable as required over ten years, goes towards the capital and maintenance costs of a hæmatological research unit to be set up by the Medical School of the University of Oxford, in conjunction with the Nuffield Department of Clinical Medicine under Prof. L. J. Witts, and the Radcliffe Infirmary Department of Pathology under Dr. A. H. Robb-Smith. A second new grant of £4,000 has been made towards the expenses of a new inquiry into the relation of infant mortality and morbidity to environment for the whole of Great Britain. This inquiry is to be undertaken by the joint committee of the Royal College of Obstetricians and Gynæcologists and the Population Investigation Committee, with help from the Institute of Child Health of the University of London. Like the inquiry into the maternity services, begun in 1945, it will also require the help of the medical officers of health and health visitors. Progress has also been made during the year in building up a comprehensive rheumatism service under the Medical School, University of Manchester; in addition to clinical work in Manchester and Preston, an experimental clinic is being established at Walkden for the diagnosis and treatment of rheumatism in coal-miners, and an investigation commenced into the role of the oral septic focus in chronic rheumatism. The five-year study of student health at the Institute of Social Medicine, Oxford, commenced in January 1947, and as a result of a conference on student health at the Institute in July 1947, student-health services which are starting at other universities will be co-ordinated with the Oxford service to achieve comparable records and statistics. The first year's work under Prof. J. Z. Young in the Department of Anatomy, University College, London, on the mechanism of learning in various animals has confirmed the hope that study of the structure of the brain and the learning powers of cephalopods (and especially the octopus) will throw light on the nature of the learning process.

New grants in the natural sciences during the year have been for a scientific study of the principles that should guide agricultural policy in Britain, and £18,000 over five years to the University of Bristol for research under Dr. C. R. Burch on the improvement of the reflecting microscope and for an attempt to solve the problems involved in the manufacture of the microscope by machinery. The agricultural study is being conducted by Mr. T. E. Eastwood, under the guidance of a committee of which Sir William Goodenough is chairman. At the University of Birmingham progress is reported in work under Prof. M. L. Oliphant upon the design and creation of new equipment for further fundamental studies in nuclear physics. An additional research fellow has been appointed to the staff working under Prof. P. I. Dee at Glasgow, and in addition to successful work with the million-volt generator and thirty-million-volt synchotron, results of fundamental interest have been obtained in the development of 'detection' techniques for use with these machines. In the biomolecular research laboratory at Birkbeck College, London, under Prof. J. D. Bernal, the X-ray analysis group is studying crystalline proteins and viruses, as well as simpler and related organic compounds which might provide clues to the structure of the proteins themselves. Dr. S. Levine's extensive theoretical work has shown that long-range forces between colloidal particles can originate in the electrical double layers at the surfaces of the particles. Results obtained in cosmic-ray research under Prof. P. M. S. Blackett at the University of Manchester have already been described in *Nature* (**160**, 855; 1947), and a cloud chamber is now operating at the Jungfraujoch Laboratory, Switzerland, for further study of these new particles. Measurements of extensive showers with a very elaborate hodoscope are being started, and fundamental work on temperature and meteorological effects of cosmic rays is continuing.

---

* Nuffield Foundation. Report of the Trustees for the Year ending 31 March, 1948. Pp. 92. (12–13 Mecklenburgh Square, London, W.C.1.)

Six research fellows are now working at the Clarendon Laboratory, Oxford, under Lord Cherwell, and the low-temperature department of the Laboratory has now been built up again; while in the small chemical laboratory of the Laboratory the use of chemical methods as an aid to exact methods in nuclear physics is being developed. At the Cavendish Laboratory, Cambridge, Dr. E. Orowan's group of research workers has developed a theory of low-temperature creep in metals and a photo-elastic method of recording the distribution of roll-pressure over the area of contact, and have investigated a new mechanism of recrystallization in cold-worked metals. In the investigation at the University of Cambridge into the mechanical properties of soil, the study of soil dynamics has centred largely on the improvement of the oscillograph apparatus for the simultaneous recording of the component soil forces on the tillage implement. A theory of the relation between the permeability of a structured material such as soil and its pore-size distribution has been checked by observation on the permeability over a wide range of moisture contents.

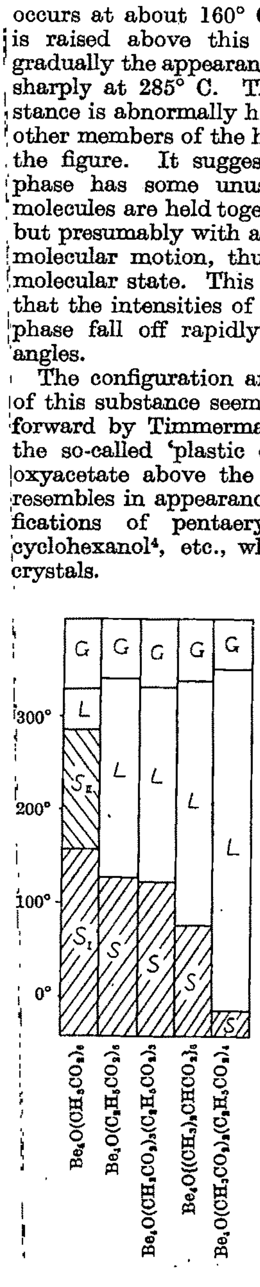
New grants in the social sciences have been made to the Department of Social Science, University of Liverpool (£7,000 over five years), for a study of group relations and an investigation into social factors of town planning; to the Social Research Division of the London School of Economics and Political Science (£20,000 over five years) towards a comprehensive study of social selection and differentiation with particular reference to the middle class; and to the Institute of Psychiatry, University of London (£20,000 over ten years), for a long-term investigation of the traditional methods of selecting students in comparison with a procedure using various psychological tests, and relation of the assessment with the subsequent careers of the individuals tested. A further grant of £1,000 to the National Institute of Economic and Social Research is to be used in support of the project, "Lessons of the British War Economy". Substantial starts are reported by the recipients of grants approved last year; the Administrative Staff College has commenced its activities, and the Population Investigation Committee has launched a large-scale field study of the trend of intelligence.

Steady progress is reported towards the realization of the Foundation's fellowship policy of a two-way traffic between the various parts of the Commonwealth and Empire of students of varying seniority and fields of interest. The Dominion medical travelling fellowships scheme has proved so successful that it is being continued, with slight modifications, for a further seven years; and the small scheme to enable practical farmers of England and Wales to study modern farming methods abroad has been extended to Scottish farmers. For medical men in the outlying parts of the African Colonies, the Foundation has made a grant of £30,000 to finance for six years periodic visits by a panel of medical consultants from Britain. Reference has already been made to the grant of £500,000 to the new National Corporation for the Care of Old People. The Foundation's own policy is to continue financial support to this Corporation, but, in conformity with its own interests in the problems of health, it will consider projects of research into causes of ageing. The report pays a tribute to Dr. J. H. Sheldon's report on "The Social Medicine of Old Age", although the publication falls just outside the year under review. Among the miscellaneous grants of the year is £1,000 a year for five years towards the maintenance and extension of the activities of the Universities Bureau of the British Empire (now the Association of Universities of the British Commonwealth).

POLYMORPHISM OF BERYLLIUM OXYACETATE

WE have found a transition of beryllium oxyacetate hitherto unrecorded. The transition occurs at about 160° C., and when the temperature is raised above this point the substance assumes gradually the appearance of soft wax, though it melts sharply at 285° C. The melting point of this substance is abnormally high as compared with those of other members of the homologous series, as is seen in the figure. It suggests that the high-temperature phase has some unusual structure in which the molecules are held together, forming a crystal lattice, but presumably with a higher order of freedom in its molecular motion, thus resembling the melt in its molecular state. This view is supported by the fact that the intensities of X-ray spectra taken with this phase fall off rapidly with increase of diffraction angles.

The configuration and symmetry of the molecule of this substance seem to fulfil the requirements put forward by Timmermans[1] for substances which give the so-called 'plastic crystals'. In fact, beryllium oxyacetate above the transition temperature much resembles in appearance the high-temperature modifications of pentaerythritol[2], tetranitromethane[3], cyclohexanol[4], etc., which are examples of plastic crystals.



The X-ray powder photographs taken with this substance slightly above the transition temperature and somewhat below the melting point are similar, but the relative intensities are not the same. Most of the lines observed can be accounted for as the lattice has a rhombohedral unit with dimensions $a_r = 9{\cdot}72$ kX., $\alpha = 54°\ 20'$, containing one molecule in it (copper $K\alpha$ radiation was used). The arrangement of molecules may be such that the centres of molecules occupy the rhombohedral lattice points; but the existence of a few lines which cannot be accounted for with this unit shows that the translation of the structure is not exactly rhombohedral but one having a lower symmetry.

It has been reported by Preston and Trotter[5] and by Beevers[6] that the symmetry of the Laue photographs of the cubic oxyacetate changes from $T_h - m3$ to $O_h - m3m$ in the interval 30–50° C. Jaffray[7] made a thermal analysis and found that at 40·5 ± 0·5° C. there is a change in the heat capacity curve typical of the λ-type. According to Beevers, this change is due to a change in the parameter values of the carboxyl oxygen atom from (−0·17, −0·06, −0·04) to (−0·17, −0·05, −0·05), as the temperature passes the transition range, thus bringing all the oxygen atoms exactly to the (110) planes. We have re-examined the substance by the Laue photographic method and found that the holohedral symmetry is first attained at 60° C. Moreover, we have found on the photographs taken with the X-ray beam perpendicular to the (111) planes a number of diffuse spots, the intensities of which are enhanced considerably on passing the transition temperature.

A tentative theory is put forward. The symmetry of the molecule in the low-temperature form is $T - 23$, and the higher symmetry of the crystal $T_h - m3$ can be described as containing two kinds of molecules the mirror images of which are arranged regularly in accordance with the symmetry of the space group. If the packing of the molecules be kept as before but the two forms of the molecules be found at random, the symmetry of the crystal would attain the higher one $O_h - m3m$ in a statistical sense. This may be explained in another way as follows. The potential change associated with the rotation of the carboxyl group around the carbon-to-carbon bond parallel to the crystallographic axis would have a maximum when the oxygen atoms pass the (110) plane, and if the height of this barrier be low compared to the thermal energy, the oxygen atoms would pass over this barrier and arrive at another position of minimum energy which lies symmetrically to the (110) plane. This may transform the configuration of the molecule to its mirror image form if the change should occur simultaneously in six carboxyl groups within a molecule. Such may be the mechanism of the above-mentioned transformation.

Another modification of beryllium oxyacetate can be obtained by sublimation[8]. It is reported that this modification is birefringent and unstable at room temperature, transforming gradually when left by itself, or rapidly by grinding, into the cubic modification. The Laue rotating crystal and the moving-film goniometer photographs show that the crystal has a monoclinic unit with $a = 13·75$ kX., $b = 9·24$ kX., $c = 16·21$ kX., $\alpha = 98° 55'$, $Z = 4$ (copper-Kα radiation was used throughout), and the corresponding space group is one of $C_s^1 - Pm$, $C_2^1 - P2$ or $C_{2h}^1 - P2/m$.

Detailed analyses of the structures of different modifications are now going on, and the results will be published later.

WE have carried out differential thermal analyses of beryllium oxyacetate in order to find accurate transition and melting points and also to examine the heat effect associated with these (Fig. 1). The observed transition and melting points are 148° C. and 286·7° C., respectively. If the sample is heated up to about 250° C. and then cooled to the room temperature, there is observed no transition phenomena in the cooling curve; this behaviour persists, for no transition phenomena is shown by the heating curve obtained on the next day (see curve II). But, when the sample is not heated beyond about 210° C., the transition in the heating curve made on the next day is always observed. The velocity of transition is accelerated by grinding the supercooled sample in an agate mortar. But this effect is somewhat complex. Details of the observation will be reported elsewhere. Comparison of the two peaks in the curves of the thermal analysis reveals that the heat of transition is nearly equal to the heat of fusion.

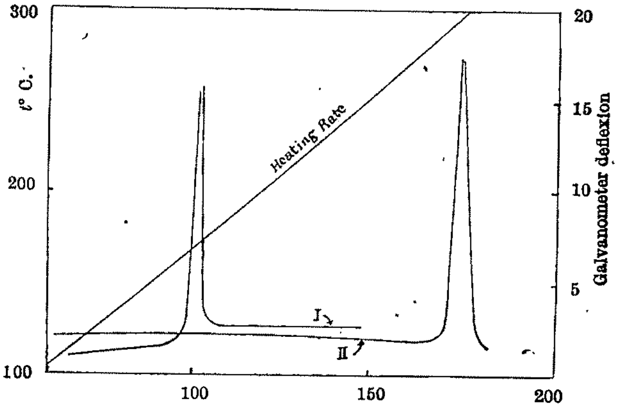

Fig. 1

We have also made a dilatometric investigation. The results are shown in Fig. 2. It is found that the thermal expansion coefficient changes at four different temperatures, namely, 32° C., 42° C., 77° C and 124° C. At all these temperatures except the

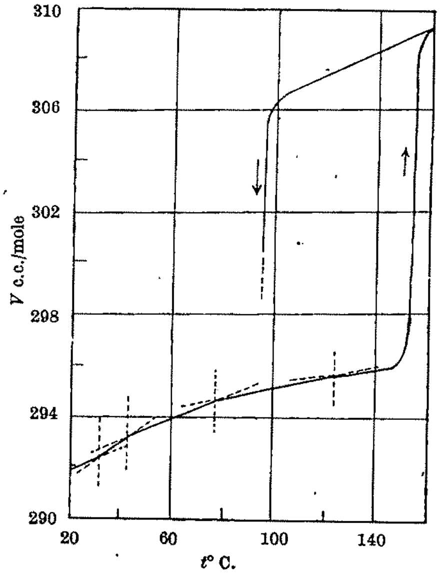

Fig. 2

e expansion coefficient decreases on the high- ature side. The second one corresponds to the ture observed by Jaffray in his calorimetric ment and reported as 40·5 ± 0·5° C. The f such changes is the largest, and the last is llest. The volume change at 148° C. is nearly cent of the volume at 25° C. Numerical data e changes and the volume change at the point not described here will be given else-

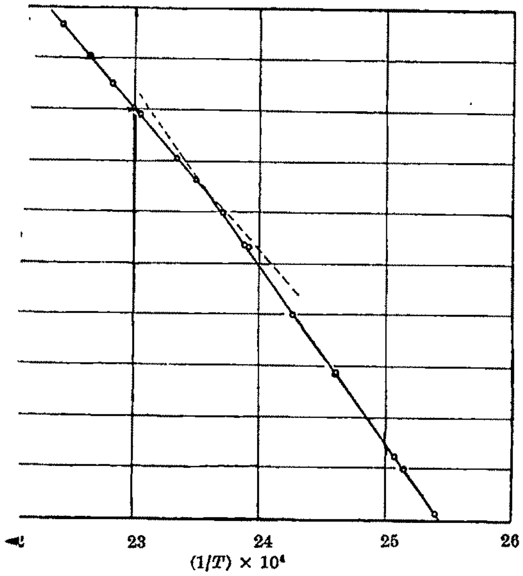

Fig. 3

have also measured the sublimation pressure of bstance below and above the transition points by usion method. The vapour pressure equation ed below the transition point is log $P =$ $4{\cdot}8/T + 15{\cdot}0299$, and above is log $P =$ $2{\cdot}8/T + 12{\cdot}6266$ (Fig. 3). From these equa- the heat of sublimation and of transition as s the entropy changes are calculated (see . The entropy change at the melting point is ated by comparing the areas of the two peaks curve of the thermal analysis with the heat of tion obtained from the vapour-pressure measure- These entropy data seem to explain why this nce has a very narrow range of liquid state in st to other members of the homologous series.

SEED STORAGE OF INDIAN FOREST PLANTS

Mr. T. V. Dent, of the Indian Forest Service, has published some valuable information on the theoretical and practical aspects of seed storage, together with a discussion of the near-related principles of the duration of seed viability, dormancy, germination and the testing of seeds (*Indian Forest Records* (*New Series*) *: Sylviculture*, vol. 7, No. 1 (Manager of Publications, Delhi)). In addition, an attempt is made to screen and correlate all available information on the duration of vitality and on the storage of seed of Indian forest plants.

Mr. Dent writes that it is suggested that the time is now ripe for the initiation of a carefully prepared programme of research into storage of seed and near-related problems, in particular pre-sowing treatments for seeds which are difficult to germinate. Action should be initiated by the central sylviculturist, and an all-India plan of action should be devised, with the co-operation of provincial forest research officers. The shortcomings of our past methods, and the lacunæ in our knowledge of seed storage matters, are revealed by the information tabulated in this record. Here we have our starting point for planning the investigations of the future.

The monograph is divided into two parts, of which Part 1 deals with general principles relating to seed storage and is divided into nine sections covering the following: the practical importance of tree seed storage in forestry, the germination of seeds, dormancy, the duration of seed viability, the collection and extraction of tree seed, methods of seed storage, the protection of stored seed from pests, the transportation of seed and the testing of tree seed. Part 2 deals with available seed storage data for Indian forest plants and includes two tables presenting in summarized form all the principal information which is at present available on the storage and longevity of the seed of Indian forest plants.

In Great Britain it is understood how important is a knowledge of how to store seed of forest trees. It is not surprising, therefore, that India has had to consider this matter carefully, since a very much larger number of tree seeds, both indigenous and exotic, are made use of in the sub-continent of India; at the present time, at least 20,000 acres of land are artificially afforested a year, and under new proposals this area may be very considerably enlarged.

FORTHCOMING EVENTS

(*Meetings marked with an asterisk * are open to the public*)

Monday, February 7

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Discussion on "Electrical Engineering taught to other than Electrical Engineers" (to be opened by Prof. A. A. Hall and Mr. H. C. Mann).

Manchester Geographical Society (at the Geographical Hall, St. Mary's Parsonage, Manchester), at 6.30 p.m.—Miss Dorothy M. Scott: "Southern Rhodesia and the Cape".

Textile Institute (joint meeting with the Society of Dyers and Colourists and the Society of Chemical Industry, at 16 St. Mary's Parsonage, Manchester), at 7.15 p.m.—Dr. E. S. Paice: "Detergents".

Chemical Society, Oxford Section (in the Physical Chemistry Laboratory, Oxford), at 8.15 p.m.—Prof. C. A. Coulson: "Localized and Non-Localized Bonds" (Alembic Club Lecture).

Royal Geographical Society (at Kensington Gore, London, S.W.7), at 8.15 p.m.—Mr. A. B. Crawford: "The Life of the Tristan Islanders".

Tuesday, February 8

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Dr. Kenneth P. Oakley: "The Origins of Tool-Making".

Zoological Society of London (at the Zoological Gardens, Regent's Park, London, N.W.8), at 5 p.m.—Scientific Papers.

University of London (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Dr. Pierre Lépine (Institut Pasteur, Paris): "Virus Research and the Virus Problem".*

Institution of Electrical Engineers, Measurements Section (joint meeting with the Utilization Section, at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. G. T. Winch: "The Measurement of Light and Colour". (To be repeated on Wednesday, March 2, at the City Council Chambers, Clarence Parade, Portsmouth, at 6.30 p.m.)

Institution of Electrical Engineers, East Midland Centre (at the Y.W.C.A., Nottingham), at 6.30 p.m.—Mr. F. J. Erroll and the Lord Forrester: "Some Projects favourable to Direct-Current Transmission, and the Role of the British Electrical Industry in relation Thereto". (To be repeated on Tuesday, April 5, at the Yorkshire Electricity Board Offices, 1 Whitehall Road, Leeds, at 6.30 p.m.; on Wednesday, April 6, at the Cleveland Scientific and Technical Institute, Middlesbrough, at 6.30 p.m.; and on Monday, April 25, at the South Wales Institute of Engineers, Park Place, Cardiff, at 5 p.m.)

British Esperantist Scientific Association (in the Psychology Department, University College, Gower Street, London, W.C.1), at 7 p.m.—Second Annual General Meeting.

Royal Photographic Society (at 16 Princes Gate, London, S.W.7), at 7 p.m.—"Integral Photography" (a paper on the Land Process).

Chemical Society, Edinburgh Section (joint meeting with the Royal Institute of Chemistry, the Society of Chemical Industry, and the Edinburgh University Chemical Society, in the Biochemistry Lecture Theatre, The University, Edinburgh), at 7.30 p.m.—Prof. R. D. Haworth, F.R.S.: "Some Recent Advances in the Chemistry of Natural Products".

Wednesday, February 9

Linnean Society of London (in conjunction with the Systematics Association, at Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Dr. John Smart: "Post-Darwinian Development of Taxonomy (Zoology)".

Chemical Society, Northern Ireland Section (joint meeting with the Royal Institute of Chemistry and the Society of Chemical Industry, in the Chemistry Department Lecture Theatre, Queen's University, Belfast), at 7.30 p.m.—Prof. A. R. Ubbelohde: "Some Problems of the Sensitiveness of Explosives".

Society of Dyers and Colourists, Northern Ireland Section (in the Queen's Hotel, Belfast), at 7.30 p.m.—Dr. T. Vickerstaff: "A Study of the Factors Controlling Dyeing Behaviour".

Society of Instrument Technology, North-West Section (at the College of Technology, Manchester), at 7.30 p.m.—Mr. C. A. Whitmarsh: "Introduction to the Measurement of Radioactivity in a Factory".

Thursday, February 10

Institution of Electrical Engineers, South-Western Sub-Centre (at the Electric Hall, Torquay), at 3 p.m.—Mr. C. A. Cameron Brown and Mr. E. W. Golding: "The Application of Electricity to Horticulture". (To be repeated on Monday, March 14, at the Imperial Hotel, Birmingham, at 6 p.m.)

Chemical Society, Liverpool Section (joint meeting with the Royal Institute of Chemistry, the Society of Chemical Industry and the British Association of Chemists, at the University, Liverpool), at 4.30 p.m.—Dr. G. Gee: "Recent Advances in the Physical Chemistry of High Polymers".

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Discussion on "The Song of Birds" (to be opened by Mr. James Fisher).

Chemical Society, St. Andrews and Dundee Branch (joint meeting with the Royal Institute of Chemistry, the Society of Chemical Industry and in conjunction with the British Association (Dundee) Trust, in the Chemistry Department, University College, Dundee), at 5.30 p.m.—Dr. W. G. Ogg: "Soil Fertility".

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—M. Brocard and M. Hussenot: "French Practical Aerodynamic Methods" (Second Louis Bleriot Lecture).

Royal Meteorological Society (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 6 p.m.—Sir Nelson Johnson, K.C.B.: "Some International Aspects of Meteorology".*

Society of Dyers and Colourists, Midlands Section (at the Midland Hotel, Derby), at 7 p.m.—Dr. L. P. Moore: "Some New American Fibres".

Women's Engineering Society (at 35 Grosvenor Place, London, S.W.1), at 7 p.m.—Mr. E. J. Steadman: "X-Rays in Medicine and Industry".

Friday, February 11

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Anniversary Meeting.

Chemical Society, Newcastle and Durham Section (in the Chemistry Department, King's College, Newcastle-upon-Tyne), at 5 p.m.—Dr. A. J. B. Martin: "Partition Chromatography" (Bedson Club Lecture).

North-East Coast Institution of Engineers and Ship
(in the Mining Institute, Newcastle-upon-Tyne), at 6.15
W. L. Hughes: "Vibration of Propeller Blades"; Prof. L.
"Underwater Propeller Tests".

Royal Institution (at 21 Albemarle Street, London, W.
—Mr. Peter Scott: "The Preservation of Wildfowl—T
Problem".

Saturday, February 12

Biochemical Society (at the Westminster Hospital Me
17 Horseferry Road, London, S.W.1), at 11 a.m.—Scienti

British Psychological Society (joint meeting with t
Group of the Physical Society, in the Hastings Hall,
House, Tavistock Square, London, W.C.1), at 2.30 p.m.—
on "The Techniques and Methods of Interpretation of Expe
Colour as carried out by Physicists, Physiologists and Psy

British Psychological Society, Social Psycholog
(in the Physiology Theatre, University College, Gower Stre
W.C.1), at 8 p.m.—Dr. J. C. Flugel: "Some Neglected
World Integration".

APPOINTMENTS VACAN

Applications are invited for the following appointme
before the dates mentioned:

Head of the Department of Pure and Applied Sci
Chemical Engineering—The Registrar, Loughborough
Loughborough (February 12).

Biochemist for the investigation of diseases of farm
The Director, Agricultural Research Council Field Station,
Newbury, Berks (February 14).

Scientific Officers or Experimental Officers with goo
degree in a biological science or in chemistry, with research e
in biochemistry, physiology, pathology, pharmacology or
chemistry, in Ministry of Supply research and development e
ments in Wilts and Hants—The Ministry of Labour and
Service, Technical and Scientific Register (K), York House, K
London, W.C.2, quoting G.550/48 (February 19).

Metallurgists (unestablished, Senior Scientific Officer,
Officer, Experimental Officer and Assistant Experimenta
grades) in Ministry of Supply research and development e
ments in London and South England—The Ministry of La
National Service, Technical and Scientific Register (K), Yor
Kingsway, London, W.C.2, quoting F.1190/48A (February

Physicists and Mathematicians (Experimental Offic
unestablished) in Ministry of Supply research and developme
lishments in Southern England and South Midlands—The
of Labour and National Service, Technical and Scientific Regi
York House, Kingsway, London, W.C.2, quoting A.398/48A
ary 19).

Senior Scientific Officers or Scientific Officers: (a)
(research experience on gaseous combustion at high press
detonation of solid explosives is desirable), (b) Physicist fo
on velocity of detonation of gases at high pressures and mea
of explosion pressures, (c) Chemist for analysis, stability and s
tests on new explosives for industrial use; Experimental
or Assistant Experimental Officers: (a) to assist in new
of physical testing and in the assessment and investigati
plosion and fire risks, (b) for the analysis of explosives samp
in the field, etc., (c) for gas analysis of mixtures of hyd
and other reactants or for physico-chemical work conne
acetylene; in a Ministry of Supply research and developme
lishment in London—The Ministry of Labour and Nationa
Technical and Scientific Register (K), York House, Kingsway,
W.C.2, quoting F.1189/48A (February 19).

Lecturer in Experimental Physiology—The Registr
University, Manchester 13 (February 25).

Statistician in the Department of Social and Ind
Medicine—The Registrar, The University, Sheffield (February

Chemist or Chemical Engineer for fundamental, theoret
experimental work including work on corrosion, a Chemical E
for development of chemical processes subsequent to the la
stage and design of plant from pilot plant to larger scale, a P
for design, development, manufacture and operation of specia
ments, including automatic controls, for chemical plant,
Mechanical Engineer for experimental work on problems
measurement and high-pressure technique and for the d
machines and plant for chemical engineering projects, in the
engineering section of a Ministry of Supply research and deve
establishment in Essex—The Ministry of Labour and National
Technical and Scientific Register (K), York House, Kingsway,
W.C.2, quoting F.1188/48A (February 19).

Professor of Organic Chemistry, and a Professor of T
ical Physics, at the University of Cape Town—The S
Association of Universities of the British Commonwealth, 32
Square, London, W.C.2 (March 31).

Director—The Registrar, Indian Institute of Science, Ban
India (April 11).

Scientist (Grade III, with honours degree in physics and
ably, experience in electronics) in the Scientific Branch,
Western Division of the National Coal Board—The Divisiona
lishment Officer, National Coal Board, 47 Peter Street, Manc

Lecturer in Physics—The Principal, Derby Technical
Normanton Road, Derby.

Health Physics and Safety Assistant Manager at the M
of Supply Division of Atomic Energy, Springfield Factory, Sa
The Staff Section, Ministry of Supply, Division of Atomic
(Production), Risley, Warrington.

Senior Lecturer in Production Engineering, Machine
and Jig and Tool Practice in the Department of Aircraft Eco
and Production—The Registrar, College of Aeronautics, Cr
Bletchley, Bucks.

Continuously in Service, Day and Night

Noon over Nanking. Dawn over the Atlantic. Blackness over the Andes. In all parts of the world, at all times of the day and night, Marconi built stations are in operation, broadcasting or sending telegraph messages and giving unrivalled service. Wherever ships and aircraft are plying, you will find Marconi apparatus guiding them, every hour of the day, every day of the week. Pioneers in Wireless Communication fifty years ago, Marconi's still maintain their leadership. Behind every new development there will be Marconi's accumulated experience. Behind every new piece of Marconi equipment there will be the honoured name as an assurance of maximum efficiency.

Marconi

the greatest name in wireless

MARCONI'S WIRELESS TELEGRAPH COMPANY LTD.,
MARCONI HOUSE, CHELMSFORD, ESSEX.

Available only to applicants excepted from the Control of Engagement Order, 1947, No. 2021, unless the situation is also excepted.

CIVIL SERVICE COMMISSION

Applications are invited from male candidates for the following permanent posts under the War Office.

(1) Senior Grade Engineer.
(2) Main Grade Engineer—Machinery.
(3) Main Grade Engineer—Waterproofing.
(4) Main Grade Engineer—Engineer equipment and refrigeration.
(5) Recruitment Grade Engineer—Internal workshop organization and procedure.
(6) Recruitment Grade Engineer—Workshop planning and layout.

All candidates must be fully qualified engineers, possessing either corporate membership of one of the Institutions of Civil, Mechanical or Electrical Engineers or qualifications entitling them to exemption from parts A and B of one of these institutions' examinations for associate membership: candidates under the latter alternatives must obtain corporate membership of the appropriate institution within two years of entry.

In addition, candidates for the different posts will be expected to have particular qualifications as follows:

For Post (1), must have had considerable experience in man management, preferably as a works manager in mechanical and/or electrical engineering industries; and should be fully acquainted with the piece work system of payment as applied to the engineering industries.

For Post (2), must possess intimate knowledge of workshop practice and layout; be conversant with the operation and characteristics of machine tools and able to compile specifications for same; have a knowledge of the Factories Act; knowledge of rubber and plaster technology desirable.

For Post (3), must possess a knowledge of the practice and theory of water-proofing army equipment and a good knowledge of the design of motor transport and army equipment; knowledge of workshop organization and equipment desirable.

For Post (4), must possess theoretical and practical knowledge of all types of engineer equipment utilized in road-making machinery, dozers, compressors, etc. A good knowledge of the theory and practice of refrigeration equipment is necessary.

For Post (5), must be experienced in workshop organization and administration, general planning and progress methods, time costing, stores accounting and contracts.

For Post (6), must be experienced in workshop planning and layout and the preparation and layout of specialized line system. Must be able to design a workshop to fulfil a particular task.

London inclusive salary scales:

Senior Grade, £1,050–£1,270 (the present vacancy is at Ashford on the scale £997–£1,192).

Main Grade, £750–£1,000.

Recruitment Grade, £475–£750.

Candidates appointed to Senior or Main Grades enter at appropriate minimum. Recruitment Grade commencing salary according to age. Provincial rates somewhat lower.

Age limits:

For Posts (1) to (4), candidates must have attained the age of 30 on January 1, 1949.

For Posts (5) and (6), candidates must be at least 25 and under 35 years of age on January 1, 1949, with extension for regular service in H.M. Forces, and, up to two years, for voluntary service in H.M. Forces otherwise than on a regular engagement or for compulsory national service under the National Service Acts.

Further particulars and application forms from the Secretary, Civil Service Commission, Scientific Branch, 27, Grosvenor Square, London, W.1, quoting No. 2382. Completed application forms must be returned by February 22, 1949.

NEWCASTLE-UPON-TYNE EDUCATION COMMITTEE

RUTHERFORD COLLEGE OF TECHNOLOGY

Principal: H. A. SCARBOROUGH, M.A., D.Sc.

Wanted, for September, 1949, Head of the Mathematics and Physics Department. Ability to prepare candidates for the B.Sc. special degree in mathematics a strong recommendation. Burnham Technical Scale for Grade II Department (£800 × £25–£950, plus training and graduate increments)

Further particulars and application form may be obtained (send stamped addressed foolscap envelope) from the undersigned, to whom completed forms should be returned as soon as possible.

THOS. WALLING,
Director of Education.

City Education Office,
Northumberland Road,
Newcastle-upon-Tyne, 1.

CIVIL SERVICE COMMISSION

The Civil Service Commissioners invite applications for the following posts in the Mechanical Engineering Research Organization of the Department of Scientific and Industrial Research:

(a) One Principal Scientific Officer or Senior Scientific Officer (according to experience and qualifications of the selected candidate) for research on problems of heat exchange. Experience of research and practice in design or operation in this or allied fields is required.

(b) Two Senior Scientific Officers for research on (i) fluid mechanics and (ii) kinematics and mechanisms. For (i) experience of research in modern fluid dynamics, with mathematical ability, is required. For (ii) experience of research on gears or of noise measurement and control would be an advantage.

(c) One Senior Experimental Officer or Experimental Officer (according to experience and qualifications of the selected candidate) to prepare detailed designs of plant, equipment and apparatus for a new hydraulic machinery research laboratory, and later to participate in experimental work therewith. Good design experience essential.

(d) One Senior Experimental Officer (Engineer) for general duties connected with the development of new laboratories, including an engineering workshop. Experience in a responsible engineering position and practical knowledge of modern machine tools would be strong recommendation.

The appointments will be for duty ultimately at East Kilbride, near Glasgow, but in the first instance service in or near London is likely to be required. Candidates must have been born not later than August 1, 1918, for posts (a) and (b) and not later than August 1, 1921, for posts (c) and (d). Candidates for posts (a) and (b) must possess a first- or second-class honours degree or equivalent qualification; for posts (c) and (d) the minimum qualification required is the higher schools certificate or the higher national certificate in engineering or their equivalent, plus experience as indicated.

Inclusive London salary scales are: Principal Scientific Officer posts, £950–£1,250; Senior Scientific Officer posts, £700–£900; Senior Experimental Officer posts, £735–£935; Experimental Officer posts, £525–£675, subject to standard abatements for service outside London, ranging from £30 on a salary of £525 to £73 on a salary of £1,250. Rates for women are somewhat lower. The appointments carry superannuation provision.

Further particulars and application forms from the Secretary, Civil Service Commission, Scientific Branch, 27, Grosvenor Square, London, W.1, quoting No. 2388; completed applications must be returned by February 22, 1949.

MILITARY COLLEGE OF SCIENCE

Shrivenham, Near Swindon, Wilts.

Applications are invited from men only for the post of Lecturer in Mathematics at the Military College of Science under the War Office. Applicants must have the following qualifications:

(1) A university degree in mathematics with first- or second-class honours.

(2) A bias towards applied mathematics is desirable; alternatively, a knowledge of statistics would be a recommendation.

The inclusive London salary scale is £400 × £25–£650, with participation in F.S.S.U.; this scale will be slightly lower in respect of employment outside the London postal area. The post is at present on a temporary basis, but may become permanent later.

Single quarters are available at the College. If, owing to the housing shortage, family accommodation in the neighbourhood cannot be obtained, it may be possible to allot War Department quarters at a fair rent until other accommodation becomes available.

Write, quoting A335/48/A, to Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, for application form, which must be returned completed by February 26, 1949.

ROYAL VETERINARY COLLEGE AND HOSPITAL

Applications are invited for the post of Demonstrator in the Department of Animal Husbandry. Candidates must be members of the Royal College of Veterinary Surgeons or graduates in agricultural science. Salary scale £400 × £25–£500 per annum. Commencing salary will be fixed within this scale according to experience and qualifications.

Applications, stating all appropriate information and giving the names of three persons to whom reference may be made, should be forwarded at once to the Secretary, Royal Veterinary College and Hospital, Royal College Street, London, N.W.1.

IMPERIAL COL

OLLEGE OF SCIENCE

Near Swindon, Wilts.

ed from men only for the
of Demonstrators at the
Science, Shrivenham, Near
nder the War Office. Details
ogether with qualifications
s, are as follows:

Mathematics. The Demon-
ired to take charge of a small
ratory and to assist in the more
tional work. A university degree
ould be a recommendation.

Ballistics. The Demonstrator
o assist in the maintenance and
instruments, mainly electrical,
measurements; he may also be
supervise their use by students.
uld possess a good working know-
icity and magnetism and of the
electronics.

3) Physics. The Demonstrator will
assist in the maintenance, develop-
vement of a wide variety of scientific
nay also be called upon to supervise
dents. Candidates should have a
nowledge of physics and preferably
egree; some experience of instruc-
ould be an added recommendation.

(4) Chemistry. The Demonstrator's
assist in laboratory instruction and
ork at the standard of a university
A university degree in chemistry,
specialization in physical chemistry,
ommendation.

(5) Metallurgy. The Demonstrator
red to assist in instructional and
work in the metallurgy laboratory.
hould possess a university degree in
an equivalent qualification, together
actical experience.

s should have not been more than
d on August 1, 1948. The inclusive
ry range is £230–£490; the range will
lower for employment outside the
stal area. The initial salary will be
ordance with qualifications and experi-
will be opportunities for private study
h, and Demonstrators will be encour-
ssisted to work for higher degrees or

WEST OF SCOTLAND AGRICULTURAL COLLEGE

The Governors invite applications for the following posts:

(1) Head of the Horticulture Department. Candidates must hold a degree in horticulture or a degree in science with a diploma in horticulture and have sound practical experience in the subject. Experience of teaching is essential and evidence of aptitude for research and investigational work is required.

Salary scale, Grade I (c), £960, rising to £1,240.

(2) Advisory Officer in Grassland Husbandry. Candidates should have a degree (preferably honours) with experience in advisory, research and experimental work in grassland husbandry.

Salary scale, Grade II (c), £760, rising to £960.

(3) Assistant Lecturer in Zoology. Candidates should have special qualifications in entomology or helminthology.

Salary scale, Grade III (Int.), men, £485 to £780; women, £415–£660.

The posts are superannuable.

Conditions of appointment and application forms are obtainable from the undersigned, with whom applications should be lodged by February 11, 1949.

N. B. BAIN,
Secretary.

6, Blythswood Square,
Glasgow, C.2.

COLLEGE OF AERONAUTICS

A Course of Lectures on "The Aerodynamics of the Helicopter" will be given at the College from Monday, March 7, to Friday, March 18, 1949.

The first week will be devoted mainly to problems of performance and the second week to dynamics, stability and control.

Fees for the course are: tuition fee: for one week. 8 guineas; for the whole course, 15 guineas. Residence charge (including full board), 15s. per day.

Copies of the syllabus and forms of registration can be obtained from the Registrar, The College of Aeronautics, Cranfield, Bletchley, Bucks.

A General Course on "Aerodynamics and Fluid Mechanics" will be given at the College from Monday, May 2, to Friday, May 6, 1949.

Fees for the course are, tuition fee: 7½ guineas. Residence charge (including full board), 15s. per day.

Copies of the syllabus and forms of registration can be obtained from the Registrar, The College of Aeronautics, Cranfield, Bletchley, Bucks.

BEIT MEMORIAL FELLOWSHIPS FOR MEDICAL RESEARCH

Notice is hereby given that an Election of Junior Fellows to begin work on October 1 will take place in July, 1949.

Junior Fellowships are normally of the annual value of £600 for three years; but candidates younger than those usually elected, or whose promise for medical research must be judged mainly on work outside that field, may be awarded a lower rate of £500 for the first two years. Candidates are asked to state whether they would be unable to accept this lower initial rate.

Candidates must have taken a degree in a faculty of a university in the British Empire or a medical diploma registrable in the United Kingdom.

Elections to Junior Fellowships are rarely made above the age of thirty-five years.

The Trustees are desirous of furthering research in mental diseases, and in the general allotment of fellowships will give some preference to a candidate proposing research on approved lines in that subject.

Applications from candidates must be received by May 14.

It is necessary for candidates to submit evidence that they can be given accommodation in the departments where they propose to work, which must be either in Great Britain or Ireland.

Forms of application and all information may be obtained by letter only, addressed to Dr. A. N Drury, C.B.E., F.R.S., Secretary, Beit Memorial Fellowships for Medical Research, Lister Institute, Chelsea Bridge Road, London, S.W.1.

For overseas candidates, forms of application may be obtained from:

The Secretary, South African Medical Council, P.O. Box 205, Pretoria, South Africa.

The Secretary, Universities Commission, Box 4061, G.P.O., Sydney, Australia.

The Department of Health, Wellington, New Zealand.

The Canadian Medical Association, 184, College Street, Toronto, Canada.

LONDON SCHOOL OF HYGIENE AND TROPICAL MEDICINE

POSTGRADUATE ACADEMIC DIPLOMA IN BACTERIOLOGY

The course for the Postgraduate Diploma in Bacteriology for the Session 1949–50 will commence in October, 1949. This is a full-time day course extending over one academic year.

The course may be taken by:

(a) Graduates in medicine or veterinary science desiring to study bacteriology as applied to medicine and hygiene.

(b) Graduates in science with a first- or second-class honours degree in chemistry, or its equivalent. For such students, the course covers the fields of general bacteriology, chemical microbiology and industrial microbiology.

Applications for admission to the diploma course must be received not later than March 1, 1949.

Further information and application forms can be obtained from the Assistant Dean, London School of Hygiene and Tropical Medicine, Keppel Street, W.C.1.

COUNTY BOROUGH OF SOUTHEND-ON-SEA

WORKSHOP STEWARD

Applications are invited for the post of Workshop Steward at the Municipal College upon work principally in connection with the chemical, physical and biological laboratories in the science section.

The person appointed will be responsible for the making, under supervision, of simple apparatus as may be required and for general maintenance. Experience of glass-blowing will be an added qualification.

Salary, Misc. Div. I, i.e., £315×£15–£360. The post is subject to the provisions of the Local Government Superannuation Act. Medical examination.

Applications, stating age, educational qualifications, experience and accompanied by copies of not more than three testimonials, to be forwarded to the Chief Education Officer, Warrior Square, Southend-on-Sea.

ARCHIBALD GLEN,
Town Clerk.

Municipal Buildings,
Southend-on-Sea.

CIVIL SERVICE COMMISSION

Applications are invited for the permanent post of Librarian in the Department of the Scientific Adviser to the Army Council at the War Office. Candidates must have been born on or before August 1, 1917, and must have the following qualifications:

(1) A good scientific background is essential and a university degree in natural science preferable.

(2) Experience of a departmental scientific reference library, including the classification of scientific literature and the preparation of abstracts is desirable.

Inclusive salary scale £525–£675. Rates for women are somewhat lower.

Further particulars and application form from the Secretary, Civil Service Commission, Scientific Branch, 27, Grosvenor Square, London, W.1, quoting No. 2396. Completed application forms must be received by February 24, 1949.

LISTER INSTITUTE

(A) BIOCHEMIST. (B) JUNIOR GRADUATE

Biochemist with research experience required for research and development work of physico-chemical nature in relation to human plasma products at the Institute's Elstree, Herts, laboratories. Salary range £500–£700, according to age and experience.

Also Junior Graduate required for work of an immuno-chemical nature at the Elstree laboratories. Commencing salary £375 or higher, according to qualifications.

Applications for either position, giving experience and qualifications, to the Secretary, Lister Institute, Chelsea Bridge Road, London, S.W.1.

COLLEGE OF AERONAUTICS

A General Course on "Certain Problems of Aircraft Structures" will be given at the College from Monday, April 25, to Friday, April 29, 1949.

The Course will include both theoretical and practical work.

Fees for the Course are: Tuition fee, 8 guineas; Residence charge (including full board), 15s. per day.

Copies of the Syllabus and forms of registration can be obtained from the Registrar, The College of Aeronautics, Cranfield, Bletchley, Bucks.

ALLEN & HANBURYS, LTD., WARE, Herts., require a young Chemist of hons. degree standard for organic chemical research. Apply, in the first instance, to the Personnel Manager.

UNIVERSITY OF DURHAM

Applications are invited for the Chair of Physiology tenable at King's College, Newcastle-upon-Tyne. The salary at present attached to the post is £1,750 with superannuation (F.S.S.U.) and family allowance. Appointment from October 1, 1949.

Further particulars may be obtained from the undersigned, with whom applications (twelve copies) should be lodged by March 31, 1949. Applicants outside the British Isles may submit one copy only.

W. S. ANGUS,
Registrar.

University Office,
46, North Bailey, Durham.

UNIVERSITY OF READING

Applications are invited for the following temporary posts in the Department of Agriculture:

(1) Research Assistant in Poultry Husbandry. Salary, about £400 p.a., according to age and experience.

(2) Analyst whose chief duties will be in connection with poultry nutrition. Salary, about £350 p.a., according to age and experience.

Applications should be addressed to the Registrar, The University, Reading, within one week of the appearance of this advertisement.

UNIVERSITY OF MANCHESTER
I.C.I. FELLOWSHIPS

Applications are invited for the above Research Fellowships, founded by Imperial Chemical Industries, Ltd., tenable in the University and available for research in chemistry, physics and allied subjects. The value of the Fellowships will be within the range £500–£850 per annum, according to qualifications and experience.

Regulations governing the award of the Fellowships may be obtained from the Registrar, the University, Manchester, 13, to whom all applications should be sent not later than April 30, 1949.

UNIVERSITY OF MANCHESTER
TURNER AND NEWALL RESEARCH FELLOWSHIPS

Applications are invited for Research Fellowships, normally of the value of £600 per annum, founded by Turner and Newall, Ltd., tenable in the University and available for research in engineering, inorganic chemistry, physics and allied subjects.

Regulations governing the award of the Fellowships may be obtained from the Registrar, the University, Manchester, 13, to whom all applications should be sent not later than April 30, 1949.

CHELSEA POLYTECHNIC
S.W.3
DEPARTMENT OF CHEMISTRY

A series of six post-graduate Lectures on "The Use of Isotopes in Biochemistry" will be given by A. Neuberger, M.D., Ph.D. (National Institute for Medical Research, Hampstead), on Tuesday evenings (7.15–8.30) from February 15 to March 22, 1949. Fee 10 shillings.

Particulars obtainable from the Principal of the Polytechnic, Manresa Road, S.W.3.

UNIVERSITY OF OTAGO
Dunedin, New Zealand.
CHAIR OF GEOLOGY

Applications are invited for the Chair of Geology. Salary is £1,225 per annum (New Zealand currency).

Further particulars and information as to the method of application may be obtained from the Secretary, Association of Universities of the British Commonwealth, 32, Woburn Square, London, W.C.1. The closing date for the receipt of applications is April 16, 1949.

MINISTRY OF SUPPLY INVITES APPLICATIONS from Mathematicians, Physicists and Aeronautical Engineers for unestablished posts in grades specified below, at the Royal Aircraft Establishment, Farnborough, and other establishments in S. England. Senior Scientific Officer, salary range £670–£860; Scientific Officer, £380–£620. Rates for women are somewhat lower. Candidates should possess good honours degree or equivalent. The posts call for experience or special interest in one of the following fields: aircraft design and structural theory, fluid mechanics and high-speed gas dynamics, statistics, ballistics, theory of servomechanisms, digital computing mechanisms. The appointments carry F.S.S.U. benefits. Opportunities to compete for established posts may occur later.

Write, quoting A.438/48/A, to Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, for application form, which must be returned completed by February 12, 1949.

THE CIVIL SERVICE COMMISSIONERS invite applications for male candidates for the permanent posts of Principal Scientific Officer and Experimental Officer in the Medical Statistical Department of the Directorate of Hygiene in the War Office. The qualifications and experience required of candidates are: Post 1. Principal Scientific Officer. (1) A first- or second-class honours degree in statistics or in a science subject combined with statistics. (2) A knowledge of biology or social medicine, or wide experience in dealing with the specific problems associated with medical statistics. (3) A knowledge of Army documentation and procedure would be of special advantage. Post 2. Experimental Officer. (1) Higher school certificate, or equivalent qualification with mathematics or a science subject as the principal subject; with subsequent experience or training in statistics. (2) A knowledge of biology or social medicine, or wide experience in dealing with specific problems associated with medical statistics. (3) A knowledge of Army documentation and procedure would be of special advantage. Candidates for Post 1 must have been born on or before August 1, 1918, and for Post 2 on or before August 1, 1920. Inclusive salary scales: Principal Scientific Officer, £950–£1,250; Experimental Officer, £525–£675. Superannuation provision will be made under the Federated Superannuation Scheme for Universities (Post 1) and the Superannuation Acts (Post 2).

Further particulars and application forms from the Secretary, Civil Service Commission, Scientific Branch, 27, Grosvenor Square, W.1, quoting No. 2390. Completed application forms must be returned by February 22, 1949.

A FIRM OF MANUFACTURERS OF photographic sensitized materials has the following vacancies in its extended laboratories, situated in the London area: (a) Research Chemist with university qualifications and some research experience in sensitive photographic materials. Applicants should have a knowledge of photographic emulsions and the various additions to photographic emulsions, and should be capable of organizing and co-ordinating research. Age, preferably between 27 and 35 years. Commencing salary according to age, qualifications and experience. Reference, R.C.2. (b) Research Chemist with university qualifications, and preferably with some experience in photographic emulsions. Applicants would be required to carry out research in photographic emulsions. Age preferably under 32 years. Salary according to age, qualifications and experience. Reference, R.C.3. (c) Laboratory Assistants to assist either in research on photographic emulsions or to assist the works chemist in factory control. Applicants should be of at least matriculation standard, and should have had laboratory experience in industry. These posts are suitable for ex-Service men with some laboratory experience. Salary according to qualifications and experience. Reference, L.A.4.

Please apply to Box 436, T. G. Scott & Son, Ltd., 9, Arundel Street, London, W.C.2, quoting reference number.

MINISTRY OF SUPPLY INVITES APPLICATIONS for unestablished Veterinary Research Posts at a research and development establishment in Wilts. Candidates must possess recognized qualifications in veterinary science with research experience in bacteriology. Selected candidates will be appointed in either of the following grades, which carry F.S.S.U. benefits: Principal Scientific Officer, £910–£1,177; Senior Scientific Officer, £670–£860. Rates for women are somewhat lower. Starting salary within these ranges will be assessed on age, qualifications and experience.

Write, quoting G.8/49A, to Ministry of Labour and National Service, Technical and Scientific Register (K Section), York House, Kingsway, London, W.C.2, for application forms, which should be returned within 21 days of the appearance of this advertisement.

GOODLASS WALL & LEAD INDUSTRIES Limited invite applications for the following positions in the Librex Works of the Associated Lead Manufacturers Limited, situated at Bootle, Liverpool. Assistant Manager. University graduate with industrial experience, preferably chemist with technical experience in control of chemical operations. Salary £800 to £1,000 per annum. Research Chemist. University graduate with research experience in inorganic or physical chemistry. A superannuation and personal insurance scheme is in operation. Applicants are requested to write, stating age, academic and other qualifications, to the Manager, Librex Works, Associated Lead Manufacturers Limited, Hawthorne Road, Bootle, Liverpool, 20.

FUNCTIONAL APPROACH TO WESTERN UNION

THE announcement on January 29 that the Brussels Treaty Powers had agreed to the formation of a Council of Europe has been described as an event which will go down in history as a milestone of our times. As such it must receive the earnest consideration of all thinking men.

In any such association of nations, the part which scientific workers have to play in the maintenance of peace has frequently been discussed. In November last the Committee on Science and its Social Relations made a report to the International Council of Scientific Unions on an inquiry into this matter, which it had carried out among representative scientific men. The replies showed general agreement that the greatest contribution which men of science can make is to stand firmly for full freedom of thought and expression and movement. This affirmation of the necessity of full intellectual freedom is linked up, moreover, with the recognition of the part which the international scientific unions have to play, as well as the United Nations Educational, Scientific and Cultural Organisation, in pursuit of international understanding and co-operation; and it should be noted that the chairman of the United States delegation to the Beirut Conference of the latter Organisation recorded the emphatic conviction of his delegation that the Organisation could only succeed on the basis of intellectual freedom. The direct contribution of science to the maintenance of peace, it seems, is to be essentially technical, though its indirect influence in other fields may not be negligible. There was little support for the idea that men of science as such could, or should, attempt to court any direct political influence.

Certain aspects of the formation and functioning of Western Union are ably discussed by Miss Barbara Ward in her recent book, "The West at Bay"*. She refers to the Middle East Supply Centre as an example of international planning during the Second World War, remarking that in some of its functions it had to deal with problems closely resembling those facing the association of the nations of Western Europe. Its success in dealing with various technical problems of supply and production then engendered the hope, expressed in these columns (152, 671; 1943; 153, 691; 1944), that it might develop into a very valuable instrument of international co-operation in the Middle East. That hope was frustrated, however, by the withdrawal of the United States at the end of the War.

Yet another instance of successful co-operation in a technical field is cited by Miss Ward to illustrate the feasibility of a Western association. During 1945–47, when it was doing its main work, the United Nations Relief and Rehabilitation Administration included in its formal constitution all the Allies, and its achievements provide convincing evidence of the possibility of running even a system of allocations and priorities on an international basis, provided the political goodwill of the participating nations is secured. Administrators whose ability and independence of mind are beyond question are also essential for success; but the possibility of forging an instrument for international planning cannot now be seriously questioned.

---

* The West at Bay. By Barbara Ward. Pp. 234. (London: Allen and Unwin, 1948.) 12*s*. 6*d*. net.

What is at issue is, of course, the way in which it should be used and the extent to which it should attempt to plan. On this Miss Ward points out that national and international experience alike suggest that planned control should be confined strictly to the essentials. Even this measure of world government will demand the sense of a great and overriding purpose and of high moral and spiritual qualities.

When, in conclusion, Miss Ward lays such stress upon those ideas of man's unique greatness but equal fallibility, of his fundamental rights and of the necessary limitations they impose on government, of the existence of an order of right and wrong, and good and evil, from which these rights are derived an which transcend man and society, she comes close indeed to the ideas disclosed and emphasized by the Committee on Science and its Social Relations. The conception of freedom which she elucidates is that which has illuminated all the debates of the past three years on the freedom of scientific work and thought in face of the military demands for secrecy. Her analysis, brief as it is, demonstrates convincingly that, however aloof men of science may keep themselves, as such, from political action, they cannot evade the responsibility for sharing in the challenging and formidable task of discovering the spiritual basis of a Western association.

Without such a basis, the prospects of a Western association of nations are slender. That much has been recognized from the start. Whatever the political means which are chosen to rally the forces of Western Europe, the terms in which Mr. Churchill at The Hague last May defined the conditions for which it is necessary to contend cannot be challenged and should commend themselves to all men of science who recognize what is at stake:

"The movement for European unity . . . must be a positive force, deriving its strength from our common sense of spiritual values. It is a dynamic expression of democratic faith based upon moral conceptions and inspired by a sense of mission. In the centre of our movement stands a charter of human rights, guarded by freedom and sustained by law. . . . After all, Europe has only to arise and stand in her own majesty, faithfulness and virtue, to confront all forms of tyranny, ancient or modern, Nazi or Communist, with forces which are unconquerable; and which, if asserted in good time, might never be challenged again."

To reach agreement on the technical questions of a Western association—such matters as defence, customs, transport, heavy industry and the like—will not be easy: to reach agreement on a political union will be a task of years. The prosaic and functional approach based on the Brussels Pact would seem to be the most practical line of development. It will call for all the help which public and private bodies in every country can give, and the recognition that the movement for Western Union requires such co-operation is an outstanding feature of the Labour Party's recent pamphlet "Feet on the Ground—a Study of Western Union". It is not often that a political party recognizes a mistake and makes amends so handsomely, and that gesture alone should encourage the co-operation from many spheres of life that will be required both to shape the functional instruments and to formulate more clearly in terms of modern life the Western tradition. The Lysenko controversy has brought to the world of science a fresh realization of the danger to the intellectual and spiritual independence which is both an essential element in a creative civilization and a vital part of that Western tradition. Freedom of thought has ever been the secret of all creative epochs and not of scientific advance alone. Scientific workers have their responsibility to rally in support of the maintenance of high standards of truth and taste, now threatened by mass hysteria, both national and class; but they can only fully discharge that responsibility in association with others.

Some of those other contributions were indicated by a meeting held in the Royal Albert Hall last April to demonstrate the support of the Christian community for the idea of Western Union; and on the Anglican side, the report of the Lambeth Conference contained some indications of an attempt to think out afresh the moral and spiritual foundations of Western Europe. The joint congress of the Classical Association and the Hellenic and Roman Societies at Oxford in August also showed that the classics have a place in Western Union and a distinct contribution to make in the formulation of a clearer understanding of the foundations of our Western civilization, with its Greek and Roman as well as Christian elements. That conference, indeed, gave a clue to a way in which the problem of specialization might be solved, and the contribution of the specialists integrated with the need for unity and a common inspiration; it gave an encouraging example of the way in which the professional man, individually and collectively, could help in the renaissance of Western Europe.

That a Charter of Human Rights has now been adopted by the United Nations has no doubt contributed to the achievement of Western Union. It gives concrete expression to one of the affirmations of the preamble to the Brussels Pact, and it should give fresh encouragement to individuals and professional associations to think out and formulate the further measures required both to secure the ultimate objective, and also the widespread understanding of the principles and ideals upon which the effective functioning of a Western association in any form depends. Upon the functioning and co-operation of such groups the preservation of individual freedom and of human rights in general will depend. The contribution of men of science will not be made solely in the technical field. Science itself is one of those cultural activities which has helped to shape the Western tradition. Scientific men in Britain might render valuable service to the cause of a Western association of nations by developing their international contacts in Europe and America. In this way they can help their American colleagues, with whom they share so much of the tradition and ideals of Western Europe, to understand something of the difficulties which make the early federation of Western Europe impracticable, as against a gradual approach to an integration preserving the diversity on which European civilization partly depends.

The war-time experience which led to the creation of such instruments as the Middle East Supply Centre, the Combined Raw Materials Board, the Combined Production and Resources Board, the Anglo-American Caribbean Commission and the Supreme Headquarters, Allied Expeditionary Force (Shaef) has shown the lines on which a form of functional union might be achieved. To secure the forging of such instruments of European union in time of peace requires more than the threat imposed by a 'cold war'. It requires the sense of common purpose, ideals and traditions of which the Brussels Pact is the embryonic expression. In his book "From the League to U.N.", Prof. Gilbert Murray gave last year an account of the work of the Committee of Intellectual Co-operation which shows how important is the task of creating a strong international culture in the defence of peace and feeedom. The task of intellectual co-operation has now passed to the United Nations Educational, Scientific and Cultural Organisation; and the main hope of Western Union and the preservation of the rich heritage of Western civilization may lie not so much in the success of functional co-operation—the crystallization of some sense of common economic and material interests—as in the extent to which that new Organisation, loyally supported and wisely used, is able to make plain, in Gilbert Murray's words, "some sense of values, of obligations, of things of beauty, which are somehow beyond question and which, at whatever cost of endurance, humanity must not betray".

CHEMOTHERAPY AS A SCIENCE

The Basis of Chemotherapy

By Dr. Thomas S. Work and Dr. Elizabeth Work. Pp. xix+436. (Edinburgh and London: Oliver and Boyd, Ltd., 1948.) 26*s.* net.

CHEMOTHERAPY was a term used by Ehrlich to denote the treatment with substances of known chemical composition of an infected host, in such a way as to destroy the invading organisms or to neutralize the toxic action of their products. A chemotherapeutic agent must therefore be a substance which has no action against the host, but specifically attacks the infecting organism and either kills it or renders it susceptible to the defence mechanisms of the host. Until recently, new chemotherapeutic agents have been discovered by accident and then subjected to chemical modification in an attempt to improve their effectiveness. The discovery of such drugs has been followed, often after an interval of many years, by elucidation of the nature of their action. There must, however, come a time when it will be possible to design drugs to inhibit processes peculiar to parasitic organisms and so produce chemotherapeutic agents on a rational basis.

It is doubtful whether there is yet sufficient knowledge of anabolic biochemistry or of the differences between host and parasite to provide such a basis, but Drs. T. S. and E. Work in "The Basis of Chemotherapy" have made a promising attempt to indicate the fundamental lines upon which such a development might be expected to take place. The book begins with a historical account of the development of chemotherapy, and the first half of the book then gives an excellent account of the present knowledge of cellular metabolism. In this section the authors summarize what is known of enzymes and their inhibition, essential metabolites and their relation to growth factors and prosthetic groups, metabolism of carbohydrate, fat and protein, together with outlines of the various oxidation and fermentation cycles involved. Here we have the known metabolism of the bacterial cell; but it should be pointed out, in a book on this subject, that much of this metabolism is common to both host and parasite, and it is very doubtful whether any effective chemotherapeutic agent can interfere in these systems. At present it seems probable that studies on the action of chemotherapeutic drugs will reveal the nature of the underlying essential metabolism rather than *vice versa*.

The discovery of the antagonism between *p*-aminobenzoic acid and sulphanilamide provided the first real indication of a possible mode of chemotherapeutic action, and this subject is examined in detail, together with its extension into the general field of drug antagonism. The authors deal with antagonism of arsenical and heavy-metal drugs and present a critical survey of the possibilities and limitations of the use of metabolite analogues. It is hoped that future editions will include some discussion of the recent reports of antagonism of penicillin and acridines by nucleoprotein and of streptomycin by lipositol, although at the moment such findings merely emphasize the gaps in our knowledge of the underlying metabolism. A point of minor criticism is that the authors several times refer to penicillin as bacteriostatic, whereas much of the later work on this antibiotic indicates that its action is lethal and irreversible.

One of the most interesting aspects of drug action on bacteria concerns acquirement of resistance, and the chapter on this subject forms the most useful and informative in the book. Resistance to penicillin and the sulphonamides is the result of selective growth of resistant mutants; these may arise by production of metabolic pathways alternative to those blocked by the drug, by increased production of the competitive analogue, by production of an enzyme destroying the drug, etc. The authors give an excellent exposition of these aspects and also deal with the possibilities of drug resistance arising other than by mutation as suggested by the work of Hinshelwood and co-workers. Finally, there is an authoritative chapter on the relation between chemical structure and activity. Subjects dealt with here include the variation of activity with structure of surface-active substances, basic dyes and sulphonamides; much otherwise scattered but relevant material on ionization and resonance effects are usefully collected here.

So far as we know at present, chemotherapeutic action can affect the cell in three ways: by alteration of its surface properties, by direct inhibition of an essential enzyme, or by competitive inhibition of an essential metabolism. The authors' avowed object is to "focus attention on the modes of action of drugs rather than upon the synthesis of ever more variants on their chemical structure", and they may be congratulated upon achieving this object. There are no data in the book on either clinical applications or the experimental side of chemotherapy, and both the medical man and the bacteriologist would probably prefer that the title should be modified to "The Biochemical Basis of Chemotherapy". E. F. G.

THEORETICAL ACOUSTICS

Vibration and Sound

By Philip M. Morse. (International Series in Pure and Applied Science.) Second edition. Pp. xix+468. (New York and London: McGraw-Hill Book Co., Inc., 1948.) 33*s*.

DR. P. M. MORSE, who has made a number of contributions to theoretical atomic physics, shows in the present book that the new mathematical techniques which have been developed for the working out of quantum mechanics can be used to analyse such problems as the behaviour of sound in rooms. A course given by him at the Massachusetts Institute of Technology led to the writing of the book. According to the preface to the first edition, which appeared in 1936, it is intended primarily as a text-book for students of physics and of communications engineering.

The first aim is to give the student a general introduction to the theory of vibration and sound, and the second to give him a series of examples of the method of theoretical physics so that he may gain an insight into the way in which a theoretical physicist attacks a problem. Presumably the student of physics whom the author has in mind is one who has approached physics via mathematics, rather than one whose bias is towards experiment. Physics students at universities in Great Britain are not usually expected to devote much time to acoustics, and the intensive mathematical treatment would scarcely be the most effective way of giving them an introduction to the physical principles of recent work in acoustics. Students of mathematical physics will find, however, that they are provided with a systematic exposition of a powerful method of handling many acoustical problems. Research workers in acoustics will be particularly interested in the last chapters, where the theoretical work of Morse and collaborators on absorption and the acoustics of rooms is summarized.

Emphasis is laid on the usefulness of determining the characteristic functions for the normal modes of vibration, the behaviour of a flexible string being examined at some length as the simplest case of a system with an infinite number of allowed frequencies. Vibrations of bars, membranes and plates are then investigated in a similar manner. Analysis of sound waves in air commences with propagation in tubes, in connexion with which the concept of acoustic impedance is first used, followed by a chapter on radiation and scattering, which includes sections on absorption at a surface and transmission through ducts.

The present edition is more than a hundred pages longer than the first one. Some parts have been rewritten; but the main change is the insertion of new material, especially sections dealing with transient phenomena by the technique of the operational calculus. The physical principles underlying the mathematics are well brought out, but there is little attempt to compare the theoretical conclusions with experimental results. Very few references are given, and the reader has to find out for himself in what respects the present treatment differs from that of the classical treatises. For the particular fields which it covers, however, Dr. Morse's book will continue to be of great value.

WORLD FOOD PRODUCTION

Feeding the Human Family

Science Plans for the World Larder. By F. Le Gros Clark. (Sigma Introduction to Science, 11.) Pp. ix+125+8 plates. (London: Sigma Books, Ltd., 1947.) 7*s*. 6*d*. net.

IT would be a thousand pities if the misleadingly modest title of this little book, and its inclusion in a series where it is a manifest misfit, were to prevent its having the widest possible circulation. It might perhaps more aptly have been called "Cold Water on Hot Springs". It is one of those rare books that combines science with humanity, that marries a passion for justice and human rights with a hard logic that faces facts. It is as much, if not more, a book for the expert as for the non-scientific inquirer.

Mr. Le Gros Clark's burning conviction that every man, woman and child in the world, without malefit of race, creed or colour, should have access to a diet that can give optimum nutrition is known to all specialists in relevant branches of science in Great Britain, and to many overseas; this conviction is even more intense than that of many of those who attended the Hot Springs Conference and founded the Food and Agriculture Organisation of the United Nations. But his appreciation of the difficulties confronting any attempt to translate into practice the ideals of the former, or even to achieve the much more limited objectives of the latter, is also greater than that of many other enthusiasts for the full larder as a condition precedent for the full life.

The argument of this short essay is already so concise that it would be folly to attempt further condensation. It covers the ground from consideration of individual, regional and national dietary patterns to world markets; it is concerned as much with the raising of crops and stock as with the transport of processed food from factory to consumer; it recognizes in agriculture an essential industry even more than a way of life. The author, in tackling the contradiction between food surpluses and simultaneous hunger, or indeed famine, has surely made it again abundantly clear that no sincere nutritionist can 'keep out of politics' and yet face the economic issues involved.

Not the least among this book's many virtues is the simple and, generally, attractive and accurate way in which it is written, and not the least among its author's claims to distinction is that the extreme seriousness of his subject never causes him to lose his sense of proportion—or indeed of humour. But perhaps Mr. Le Gros Clark's greatest merit of all is that not only does he see the wood as well as the trees, but that he has also with scrupulous fairness and great technical knowledge examined many of the trees against which some of the world's experts in food and agriculture have been barking their individual and collective shins. He has, moreover, on many occasions shown those experts the way—and generally the only way—in which those trees can be cut down, to make a path through the jungle of anarchic production and inequitable distribution to that world of plenty now so often promised by the United Nations. A. L. BACHARACH

ANALYSIS OF OSCILLATIONS

Frequency Analysis, Modulation and Noise

By Dr. Stanford Goldman. (Radio Communication Series.) Pp. xiv+434. (New York and London: McGraw-Hill Book Co., Inc., 1948.) 36*s*.

THE manner in which this book has been written enables any one of the subjects mentioned in the title to be studied alone; but there are sufficient cross-references to indicate the relationships between them. Much of the material contained in the first section, dealing with Fourier analysis, can be found elsewhere; but it is presented here in a form particularly useful to radio engineers. The author maintains that mathematics should not be regarded merely as a convenient tool or a shorthand language to facilitate the solution of engineering problems, but as a subject exhibiting natural phenomena of its own. In support of this argument he mentions the many scientific discoveries which were made as a result of a mathematical investigation rather than by planned experiment. Certainly the mathematical treatments are presented in such a way that their practical importance is constantly in mind.

The comparatively short section which deals with the basic theory of modulation again contains material which can be found scattered among various text-books; but more than usual attention has been paid to the fundamental similarities and differences between the various types of modulation.

The chapters on noise occupy half the book and are based largely on papers which have been published during the last few years. The importance of a statistical approach to the subject has been given an emphasis which will be particularly valuable to those readers with no previous knowledge of noise phenomena. Random noise, of the type caused by shot-effect in valves and thermal agitation in impedances, has been treated at length; but atmospheric and man-made noise are worthy of more than the brief mention given to them. Space might have been found also for the important subject of crystal noise, and a treatment of the interaction of non-random noise with a signal would have been useful to those concerned with jamming techniques.

The author's teaching experience has enabled him to produce a book suitable for students, in that many queries on interesting side-issues have been anticipated. A useful selection of exercises has been introduced at appropriate points in the text. At the same time, the clear lay-out of the text and diagrams, the full list of contents, and the index make the book equally useful for reference purposes.

In cutting down the mathematics to the essentials, the author has not forgotten those who wish to study the subjects more deeply, and an adequate supply of references to original papers is provided. As is often the case in American publications, however, a number of valuable papers published in British journals find no mention. F. HORNER

SYMPOSIUM ON HORMONES

Recent Progress in Hormone Research

The Proceedings of the Laurentian Hormone Conference. Vol. 2. Edited by Gregory Pincus. Pp. v+427. (New York: Academic Press, Inc.; London: H. K. Lewis and Co., Ltd., 1948.) 8 dollars.

VOLUME 2 of the "Recent Progress in Hormone Research" is in effect the *Proceedings of the Laurentian Hormone Conference* for 1946. This meeting has become a very successful affair and is widely attended by workers connected with this field. The volume at present under consideration is largely concerned with the metabolism of hormones. It is divided into five parts, and each paper is followed by a summary of the discussion, with the names of those taking part and their comments given in considerable detail. As a rule, discussion reported long afterwards makes poor scientific reading; but it must be stated that in this volume the editors have obviously gone to great trouble to cut out the monosyllabic inanities that so frequently disfigure this type of discussion.

Section 1 is entitled "Physical Methods in Hormone Research" and consists of two papers. The first, by R. N. Jones on the characterization of steroid hormones by ultra-violet and infra-red spectroscopy, is an extremely valuable account of this very modern development in North America. It serves as an excellent introduction to the important and complicated work being performed by Dobriner and his colleagues. It is very difficult for the British reader to appreciate the importance of infra-red spectroscopy, as hitherto we have not had the apparatus. These beautiful self-recording infra-red spectroscopes are commonplace instruments in America, and they greatly speed up the investigation of steroid excretion products. The discussion on this paper is particularly interesting and is opened by Dobriner. The second paper, by Friedgood and Garst, is on the identification and determination of œstrogens by ultra-violet spectroscopy. Here again the European reader can see the enormous importance of these automatic and self-recording instruments. This paper indicates that the excretion of œstrogens, which has hitherto been very unsuccessfully investigated, will now yield results to this type of method, and a new field has therefore been opened.

It is not possible to consider the remaining four sections in the same detail, but they follow the same method of presentation. They are concerned with the control of the pituitary, the metabolism of certain steroid hormones, the hormonal regulation of metabolism, and a final section on clinical endocrinology. This last is particularly interesting and contains three papers. The first, by E. P. McCullagh, is on sex-hormone deficiencies; the discussion following this paper is particularly interesting and can be read with great profit. The second paper is on adrenal cortical tumours and Cushing's syndrome, and is by E. J. Kepler, R. G. Sprague, H. L. Mason and M. H. Power. This again is interesting in that it deals with the excretion products, and it is certainly a very valuable contribution to this subject.

In conclusion, the volume is very definitely an essential one for workers interested in endocrinology. Each section has an adequate series of modern references, and the reader may be certain that if he is familiar with this work he will at least be as up to date as the book itself. E. C. DODDS

Organic Analytical Reagents

By Prof. Frank J. Welcher. Vol. 3. Pp. xi+593. Vol. 4. Pp. xiii+624. (New York: D. Van Nostrand Co., Inc.; London: Macmillan and Co., Ltd., 1947.) 44*s.* net each.

IT would appear that these two volumes complete the author's survey of organic substances used in analysis. Volume 3 deals with heterocyclic nitrogen compounds, oximes and acidic imino compounds, and volume 4 with a number of groups of compounds, including alkaloids, other natural substances and various classes of dyes. Among the more important sections in volume 3 are extensive reviews of the uses of dimethylglyoxime (60 pages), cupferron (41 pages), and dithizone (83 pages), with detailed discussions of the conditions for their use and the factors determining the stability of the complexes formed with metals. The bibliographies in these three sections alone contain some 670 references to the literature.

The usefulness of these volumes as a work of reference would be much increased by the addition of combined indexes covering all four volumes. The analyst who uses them to find what reagents are suitable for the detection or determination of a given metal will otherwise have to search four indexes in every case. The general arrangement of the organic substances is also in some respects arbitrary; for example, the reagent 8-hydroxyquinoline is found in volume 1 under phenols and not in volume 3 under heterocyclic nitrogen compounds, so that in the absence of a combined index the search for a given organic reagent will also often involve the perusal of more than one list. However, this is a minor point, and there can be no doubt that these volumes are the key to an enormous amount of detailed information and will be of great value to the practical worker. G. M. B.

The Birds of Tropical West Africa

With Special Reference to those of the Gambia, Sierra Leone, the Gold Coast and Nigeria. By Dr. David Armitage Bannerman. Vol. 6. Pp. xxxix+364+14 plates. (London: Crown Agents for the Colonies, 1948.) 35*s.*

AFTER a gap of eight years due to the War and its after-effects, publication of this important work is resumed with the appearance of the sixth volume; and one is glad to note that the remaining two volumes are ready for press. The present volume covers seven families of the Passeriformes; the seventh will deal with the weaver-birds; and the eighth will contain additional information that has meanwhile come to hand on the subjects of the first five volumes. This last will certainly be an essential part of the work, as the first volume appeared so long ago as 1930, and something of the kind would have been necessary even if the period of issue had not been prolonged by the War.

The whole work gives a systematic account of all the species of birds known to occur in the Gambia, Sierra Leone, the Gold Coast and Nigeria. For each species there is given a description, with notes on field identification, and an account of what is known of its range and local distribution and of its habits. Such comprehensive documentation for the avifauna of tropical territories is quite unusual, and the Governments of the four Colonies have done well to sponsor the undertaking. The work will provide an invaluable base-line and guide for all further ornithological studies in the area, about the birds of which there is naturally still a great deal to be discovered. In congratulating the author on the approaching completion of his task, one is also glad to note that the standard of production has been well maintained in this post-war volume.

The Petrography and Petrology of South African Clays

By V. L. Bosazza. Pp. xv+313+18 plates. (Johannesburg: The Author, 39 Barkly Road, Parktown; London: Percy Lund, Humphries and Co., Ltd., n.d.) 42*s.*

THIS volume serves a useful purpose by bringing together a variety of chemical, physical and petrological data which have been obtained by the author and others over a period of years. It deserves to be referred to frequently, and one must regret, therefore, that the arrangement of the text makes reference difficult. The numerous analyses are quoted mainly as illustrations in the development of a general thesis on the nature of clay, and consequently data on the same or neighbouring clay deposits are often widely scattered. The index is not sufficiently complete to repair this fault.

The term 'clay' is interpreted in a wide sense, and analytical data are given on soils, siliceous deposits, iron–alumina hydrates and tillite, as well as on such materials as fireclays and kaolins. There is an almost complete absence of data obtained by modern physical techniques (X-ray diffraction, electron microscopy, differential thermal analysis), and the author's reference to the X-ray method (p. 167) suggests that he does not appreciate its present possibilities.

The book is very legibly reproduced from typescript by the 'Replika' process, but readability is impaired by numerous errors in the original typescript. The voluminous list of general references indicates a thorough acquaintance with the literature of clay mineralogy, and most readers should find in it something new to them. DOUGLAS M. C. MACEWAN

Mereside Chronicle

With a Short Interlude of Lochs and Lochans. By C. F. Tunnicliffe. Pp. 200. (London: Country Life, Ltd.; New York: Charles Scribner's Sons, 1948.) 42*s.* net.

MR. Tunnicliffe's "Mereside Chronicle" is an account of peaceful waters in lovely country settings, where birds of many kinds disport themselves undisturbed.

As a bird artist Mr. Tunnicliffe is not only well known to the ornithological world but also to a wider public. He is skilled in depicting feathered life, having that delicacy of touch which is necessary for the successful portrayal of birds.

The illustrations to this handsome volume are many; that used on the jacket, of Canada geese and goslings, being particularly satisfying, for one reason because the black, white and grey subject is especially suitable for reproduction in monochrome.

It is a pity that some of the lovely subjects could not be reproduced in full colour, for the artist we know is as much master of the brush as he is of pencil and pen.

By the way, Mr. Tunnicliffe does not confine himself to English subjects, and his sketches of divers in the Highlands are full of life, as also are other pictures of Scottish birds. F. P.

CHROMATOGRAPHY AND ION-EXCHANGE

RECENT years have seen the development of many new techniques of importance to the chemist; of these, chromatography and ion-exchange have received special attention of late. A well-attended discussion of these methods, arranged by the Chemical Society, was held on November 25, in the Chemistry Department of the Imperial College of Science and Technology, an afternoon session being devoted to chromatography (including partition chromatography), while ion-exchange was dealt with in the evening.

In opening the afternoon meeting, the president, Sir Ian Heilbron, remarked that this was a new departure for the Society or, more correctly, a return to earlier practice. He paid tribute to Dr. R. P. Linstead, who had been largely responsible for arranging the discussion, and called on him to introduce the speakers and the subject.

Dr. Linstead indicated that although the title of the discussion was wide, it would be limited to chromatography and ion-exchange. These resemble each other in being usually operated in columns in which there occurs the distribution of substance between a solid and a liquid phase in a continuous and moving system. There are similarities also to fractional distillation and solvent extraction. Dr. Linstead said that, in addition to the applications of these techniques, speakers would also deal with the principles underlying them, for many of the failures of earlier workers had been due to a lack of knowledge of fundamentals; in introducing the speakers he gave a particularly warm welcome to Dr. Stig Claesson, of Uppsala, Sweden.

The afternoon discussion was opened by Dr. E. Glueckauf with a paper on "Factors Influencing the Efficiency of Chromatographic Separations". He pointed out that there are three fundamental factors to consider, namely, non-equilibrium, diffusion, and theoretical plate effect, and equations were derived summing the influence of these on the form of the boundary between two solutes. The relation of these factors to such experimental variables as grain size, flow-rate, column diameter, temperature and uniformity of packing was considered, and it was shown that for ion-exchange the non-equilibrium factor is the most important one. From this it can be deduced that there are advantages in having a small grain diameter, a low effluent velocity and a high temperature. In organic chromatography, where equilibrium is rapidly achieved, the predominant factor is the plate effect; with a low separation factor it is desirable to have a small grain-diameter and long narrow columns. Examples were given illustrating these points.

Dr. Claesson, who was warmly received, then spoke on "The Adsorption Analysis of High Molecular Substances", and described some of his recent work on the chromatography of high polymers. For this work some changes have been made in the experimental procedure, for it has been found that the insertion of several smaller column-filters after the first one increases the sharpness of the front boundaries; changes in the concentration of the solution leaving the chromatographic column are followed by changes in the refractive index. The advantages of activated carbon as an adsorbent were referred to, and results obtained with such substances as polymethyl methacrylate, polyvinyl acetate, nitrocellulose, glue, etc., were described. Contrary to the behaviour of substances with low molecular weight, the adsorption of these macromolecular materials decreases with increasing molecular weight, the change of behaviour occurring in the region between 5,000 and 10,000. Frontal analysis has been mainly used; but displacement development and elution analysis have also been employed. The best results are obtained with very dilute solutions, and, by extrapolating to zero concentration, a good approximation of the weight distribution function is obtained. The results also agree with those arrived at by fractional precipitation followed by ultracentrifuging. In the field of high polymers, adsorption analysis is useful in determining the degree of polymerization, in determining the purity of a material, or in obtaining information as to branching or end-groups in a polymer chain.

Dr. A. J. P. Martin, one of the pioneers of partition chromatography, then spoke on "Partition Chromatography in Relation to Other Methods of Purification". The enrichment factor of two substances relative to one another in different phases depends on the difference in the energies required to move them from one phase to the other. The energy can comprise Van der Waals forces, hydrogen bonds, or ionic forces. The influence on the partition coefficient of hydrogen bonding with the solvent was discussed, and it was pointed out that whereas the partition coefficients of serine and alanine are the same, that of tyrosine is much more favourable in collidine than the partition of phenylalanine. With ionic substances on buffered columns it is possible to follow changes in the eluate by determinations of conductivity. An automatic apparatus for collecting fractions and determining conductivity was described, and some of the chromatograms obtained with crude penicillins and other materials were shown.

"The Separation of Inorganic Substances on Cellulose" was then dealt with by Dr. R. P. Linstead. Hitherto, partition chromatography has been applied only to organic substances, but work at the Chemical Research Laboratory at Teddington has revealed that many inorganic separations can be achieved by this technique, whether carried out on paper strips or on columns of cellulose. The method consists in bringing together into contact the inorganic substances to be separated, cellulose and a suitable organic solvent which usually contains acid or some other reagent. The system also contains water, which is present either as a normal constituent of the cellulose or through deliberate addition to the solvent. Activation of the cellulose by nitric acid is advantageous in many cases. It was shown that several factors may play a part in these separations, such as sorption on the cellulose, partition between the solvent and water, and complex formation. The technique can be employed for analytical and preparative purposes, and examples of both were given. Actual separations were demonstrated during the lecture.

The final speaker at the afternoon session was Dr. C. E. Dent, who described the separation of amino-acids and polypeptides by partition chromatography. Three methods were dealt with, the silica-gel column, the potato-starch column, and the filter-paper technique in one- and two-dimensional forms. The merits and disadvantages of these methods were discussed. For the study of biological fluids the paper chromatograph has provided the most useful procedure for the separation of complicated mixtures of peptides and amino-acids. Only microgram quantities of material are required, while the resolving power is high. The various spots on a chromatogram can be identified by comparing their position with those of known substances on a standard chromatographic map. Such a map was shown containing more than sixty amino-acids and related substances.

A general discussion followed in which a considerable number of questions were put to the various speakers.

The evening session, under the chairmanship of Dr. R. P. Linstead, was opened with an introductory paper by Prof. C. W. Davies. Prof. Davies pointed out that, in separations of acids on a basic exchanger, the optimum *p*H may be lower than the calculated value, owing to the existence of a zeta potential. He also emphasized that, in organic separations, the simple ionic mechanism may be modified by specific adsorption effects. The non-ionic adsorption of acids on acidic resins may be as high as 1 m.equiv./gm., a value which is of the same order as the total ionic capacity.

The second paper, "The Properties of Ion Exchange Polymers in Relation to their Structure", by N. E. Topp and K. W. Pepper, was read by Dr. Pepper. The influence of macromolecular structure, for example, degree of cross-linking and nature of chemical bonds, on such properties as swelling, solubility and chemical stability was outlined. Curves relating the capacity of an exchanger of known preparation to the equilibrium *p*H were presented. Monofunctional cation exchangers, containing only one type of acidic group, namely, sulphonate alone, carboxyl alone and phenolic hydroxyl alone, were first described. With sulphonated cross-linked polystyrene, the capacity is independent of *p*H over a wide range, and agrees closely with the value calculated from the sulphur content. The capacity of the carboxylic and phenolic exchangers varies with *p*H, and indeed it is not possible to obtain a limiting capacity of the latter material. The capacity-*p*H curves of polyfunctional exchangers, containing, for example, sulphonate and hydroxyl, carboxyl and hydroxyl, consist of segments characteristic of the ionizable groups present. The results emphasize the advantages of monofunctional exchangers in separation work, in that only one set of fundamental data, for example, distribution coefficients, exchange-rates and swelling, is required.

Dr. J. F. Duncan read the paper "Chromatographic Studies of the Sodium–Hydrogen Ion Exchange Equilibrium", by J. F. Duncan and B. A. J. Lister. Elution curves have been obtained for the sodium–hydrogen ion exchange system, and the mass action constant K_a determined by three methods: (*a*) by application of the Glueckauf equation; (*b*) by measurements of the elution volume necessary for solutions of different hydrogen–sodium ion ratios; (*c*) by the batch equilibrium method. The concentrations of sodium ions in each case are measured by use of the 14·8-hour half-life sodium-24 activity. The method is applied to two exchangers, 'Dowex 50', a simple sulphonic acid exchanger, and 'Amberlite I.R. 100H', a mixed sulphonic-phenolic exchanger. The elution curves obtained are independent of the flow-rate in a range of $1 \cdot 75 \times 10^{-3}$ to 10^{-2} cm./sec., showing the system to be in equilibrium. In the case of 'Amberlite I.R. 100H', a further small uptake of sodium ions occurs after the initial break-through due to exchange of the phenolic hydrogen ions. The capacity of 'Amberlite I.R. 100H' at *p*H 7 is 1·63 m.equiv./gm. and at *p*H 11 is 2·52 m.equiv./gm., of which only 1·50 m.equiv./gm. are due to exchange of the hydrogen atoms of sulphonate groups. The capacity for 'Dowex 50' at all *p*H's is 4·3 m.equiv./gm., a somewhat lower value than that given by American workers. With both resins, K_a remains constant for molar fractions of sodium ions in solution which are between 0·2 and 0·8, but rises significantly for molar fractions below 0·1. The values of K_a over the constant range are 1·24 ± 0·015 for 'Amberlite I.R. 100H', and 1·52 ± 0·015 for 'Dowex 50'.

The paper, "Equilibrium Studies with a Cation-Exchange Resin", by J. A. Kitchener and T. R. E. Kressman, was read by Mr. Kressman. He presented a number of interesting generalizations regarding the relative affinities of various cations for a phenol-sulphonate resin. Broadly, the affinities increase with increasing charge, but there is a considerable overlap. Contrary to common assumption, this is not in accordance with a simple Coulomb model. The distance a_0 of closest approach to cation and anion is the determining size-factor for the alkali metals. It may be for divalent ions also, but the effect is largely masked by incomplete dissociation of the salts. In contrast to the simple metal ions, the affinity of large organic cations increases with increasing size up to a limit depending presumably on the pore size of the resin. Incomplete dissociation is an important factor with the thallous and many polyvalent cations, and also with weak acids. The chief effect of concentration is that predicted by the law of mass action for such solid–liquid systems, namely, negligible influence for solutions containing cations of equal valency, and increased adsorption of ions of higher valency with increased dilution. Complex-ion formation may greatly reduce ion exchange, which is also influenced by the nature of the solvent.

This interesting contribution was followed with a paper by Dr. S. M. Partridge, who spoke on "Separation of Amino-acids by Displacement Chromatography on Ion-Exchange Resins". Dr. Partridge described the fractionation of a hydrochloric acid hydrolysis product of commercial egg-albumen on a column of 'Zeo-Karb 215'. Since the amino-acids, tyrosine and phenylalanine, behave irregularly on the column, these are first removed by adsorption on prepared charcoal. The mixture of amino-acid hydrochlorides (containing a small excess of hydrochloric acid) is applied to the column, and the mixed band so obtained is developed by displacement with 0·15*N* ammonia; the effluent solution is collected by means of an automatic arrangement in sixty-four fractions, each of 90 ml. The flowing chromatogram is analysed by paper chromatography, and the results show the presence of seven discrete bands: 1, aspartic acid; 2, glutamic acid, serine and threonine; 3, glycine and alanine; 4, valine and proline; 5, leucine, *iso*leucine, methionine and cystine; 6, histidine and an unidentified substance; 7, lysine. Arginine has a greater affinity for the resin than ammonia, and thus it remains on the column. Modifications in the experimental conditions, which may be used to effect a further separation of the components of the individual bands, were also described.

The last paper, "Ion-exchange Properties of Alginates", by I. L. Mongar and A. Wasserman, was read by Dr. Wasserman. Using a flowing system with highly swollen alginate in fibre form, the ratio k_1/k_2 and the velocity coefficient k_2 have been estimated for the following reaction :

$$\mathrm{Ca}\,Alg + \mathrm{NaCl} \underset{k_2}{\overset{k_1}{\rightleftarrows}} \mathrm{CaNa}\,Alg + \mathrm{CaCl_2}.$$

The calculation of k_2 is based on a knowledge of the diffusion coefficient of calcium chloride in calcium alginate. The value of k_2 obtained is independent of the surface/volume ratio of the gel, and is only moderately influenced by the sodium chloride concentration, pH and temperature.

WIND AND OCEAN CURRENTS

A GEOPHYSICAL Discussion on "Wind and Ocean Currents" was held in the rooms of the Royal Astronomical Society on November 26. The chairman, Dr. A. T. Doodson, emphasized the great complexity of the subject, and gave a brief summary of its various aspects.

The list of problems is headed by the tangential stress between air and water, and this is related to the problems of turbulence in general, and of hydraulic flow. In pipes and channels, the roughness factor remains constant at any one place; but the surface of the sea is hydrodynamically smooth in the early stages of wind action and hydrodynamically rough in the later stages as the waves are developed. It may be expected that there will be considerable variation in the mechanism by which one fluid acts on the other in the varying conditions. The critical velocity of wind for the setting up of waves, as given by Jeffreys (110 cm./sec.), appears to be well established; a second critical value of about 700 cm. per sec., about which there is a rapid change in the stress coefficient, appears to correspond to the change from laminar to turbulent flow. In the earlier stages of development of waves, the surface tension of the water plays a part, but there is still some obscurity with regard to the mode of formation of waves in the initial stages.

After a wave is well established, its growth brings other considerations into prominence. Some investigations by Jeffreys, which showed how the pressure variations on the various parts of the wave influenced its growth, have been supplemented by Sverdrup and Munk, who have added a term depending upon the tractive forces which exist when the waves are well developed.

It is in connexion with well-developed waves that practical interest has lain in recent years. Naval operations off beaches, for example, have stimulated investigations into waves of large amplitudes, in the first place, and thence to associated waves. The laws of decay of wave systems are still somewhat obscure as there are two causes of decay: the air resistance as the wave progresses in calm air, and eddy viscosity. It has been recently stated that the former is the sole factor; but this may be doubted for large waves.

The next stage of the problem is that of the transport of volume. In this the part played by the waves tends to go out of sight, but should not be forgotten. Also the influence of the earth's rotation becomes prominent, though it receives little consideration with regard to the genesis and growth of waves. Ekman's theory of wind-driven currents is well established, but is being developed to allow for the influence of boundaries, at the bottom or near the coasts.

Finally, there is the problem of the gradients of surface set up in restricted seas. In this, further considerations arise, bringing in the variation of depth, the free period of the sea, and the characteristics of the atmospheric disturbances, as well as the decay. The part played by wave action in the absorption of energy in these storm surges may be of some importance. This problem differs from that of waves in deep water in that the bottom friction also is of importance. In this end-problem very striking progress has been made in recent years.

To sum up, the problems range from molecular effects to large-scale effects, and it is their interrelation which needs to be borne in mind when considering the details.

Dr. G. E. R. Deacon pointed out that the energy required to maintain the circulation of water in the oceans can be supplied by the effects of heating, cooling, evaporation and precipitation, and by the stress of the prevailing winds on the surface. Some of the deep-water movements which have velocities of the order of 1 cm. a second may prove to be convection currents, but various lines of investigation show that the surface currents in the oceans, which flow much faster, must derive most of their energy from the wind.

Ekman's theory of wind currents requires that the drift at the surface, in deep water far from land, should be directed 45° to the right of the wind in the northern hemisphere. The average inclination of the surface drift to the wind in different parts of the ocean has been studied by Krummel, Jeffreys, Durst and others, and it proves to be approximately 45°. Jeffreys, interested in the degree of turbulence in wind currents, mentions that this close agreement confirms one of Ekman's basic assumptions, that the eddy viscosity does not change with depth in the water layer affected by the current; but its magnitude, determined by comparing the observed velocities of wind and current, is of the order of 1,000 times as large as the value of eddy viscosity required by Jeffreys's theory of wave generation. This discrepancy is confirmed by recent work, and waves which are known to travel thousands of miles would be damped out in a few hours by viscosities as large as that required to generate wind currents. No explanation has been found for the discrepancy.

Another effect of the wind is the formation of convection cells in the water. Langmuir noticed that weed in the Sargasso Sea became arranged in parallel lines down wind, and showed, by careful measurements in a lake, that such lines mark zones in which the surface water is converging and sinking; midway between them he found that the sub-surface water was rising and diverging. A further study was made in the Gulf of Mexico in winds of force 2–4 by Woodcock. He prepared a hundred special numbered drift bottles, each with the minimum buoyancy to keep it awash at the surface, and rowing a small boat across the wind he threw out one bottle every 2 metres. Within 3–5 minutes, the bottles were always re-formed into new lines parallel to the wind. From Langmuir's work and his own it was known that the water in the convergences moves down wind more rapidly than the water between them, and it was assumed that the leading bottle in each line was dropped nearest a convergence. If the convection cells were symmetrical, the leading bottle in each line should be followed by equal numbers from the left and the right; in all but three of his eighteen experiments, however, there were more from the left, and the average was 60 per cent. He concludes that the right-hand convection cell is most strongly developed.

Attempts have been made to use the effect of the earth's rotation to explain the symmetrical development of the convection cells, but without success. Munk has suggested that the convection cells are combined with a drift of the Ekman type.

Mr. F. Ursell then outlined an investigation of waves as they are affected by the rotation of the earth. It was shown by Stokes that regular trains of water waves are accompanied by a mass transport in the direction of propagation, provided that the effects of non-conservative forces such as the viscous forces and the Coriolis force are negligible so that the waves are free from vorticity. It has been suggested that this transport might set up large-scale ocean currents. However, in geophysical applications, the Coriolis force may not be negligible and vorticity may be generated. This question requires mathematical study. An idealized problem has been considered by Mr. Ursell in which the geopotential gradient (including the centrifugal force) is constant in magnitude and direction; so the wave motion may be thought of as taking place on a plane earth, on which there is a Coriolis field. In the first place, considering regular wave trains which can travel unchanged in such a field, it is necessary to take the non-linear equations of motion, as the mass transport is considerable only for waves of substantial height. But for non-linear equations the principle of superposition does not apply, so that we cannot hope for a complete solution of the equations. (An illustration was given of the difference between linear and non-linear behaviour.) Nevertheless, a good deal can be said about the mass transport. Mr. Ursell began by showing that the plane touching all the crests is normal to the direction of gravity. Then, by an extension of Bernoulli's theorem, it was shown that the mass transport, if any, must be in the direction of propagation. Finally, Bjerknes's theorem on the circulation along a circuit moving with the fluid was used to show that the mass transport at any depth is zero, so that the fluid particles move in closed orbits. The stationary state of waves on a rotating earth must therefore approximate closely to the type studied by Gerstner (1802) rather than to Stokes waves. The foregoing arguments do not apply on the equator.

Bjerknes's theorem may also be applied to the non-stationary state. Consider an area of still water which is being invaded by waves. The motion is initially irrotational, so that the waves formed in this area are initially of Stokes type. As they build up, a mass transport is set up. Bjerknes's theorem then shows that this current changes its direction continuously, the direction turning through four right angles in 12 cosecφ hours, where φ is the latitude. Ocean waves should therefore be accompanied by rotating inertia currents. Such currents have hitherto been explained as set up by a wind drag on the surface which ceases when a current has been established. This requires a large value of the eddy viscosity, which would lead to very rapid damping of the resulting motion. It may be that the wave mechanism described here will serve to explain some known inertia currents satisfactorily, but further measurements of waves are needed before a detailed comparison can be made.

Lastly, Mr. R. H. Corkan gave an account of the derivation of certain constants of the sea, of interest to oceanographers, a by-product of his work on storm surges. These surges are waves of much longer periods than surface waves, and the associated transport of water is of great importance. It might be thought that a single well-developed surge would give information as to the period of the oscillation, and that its rate of decay would give an approximate value of the coefficient of eddy viscosity. It was stated that such a simple method cannot be used for surges experienced in the Thames, since the surge has three main contributions: one from local winds, one from winds over the North Sea, and one from a surge propagated inwards from the north of Scotland and travelling around the North Sea in an anti-clockwise direction. The latter contribution is a passing wave, and its rate of decay cannot be ascertained from observations at a single place, such as are applicable in studying the decay of an oscillation of the sea itself. The removal of such an external effect and the allowance for periodic variations in the winds are necessary before the data can be utilized for the desired constants.

Mathematical formulæ for the oscillation of the sea under the influence of a variable wind were described. These involve the free period of the sea and the eddy viscosity. After the wind dies down, there is a decaying oscillation with the free period, which was quite accurately determined from a large number of surges as 30 hr., and the ratio of the first positive amplitude to the next negative amplitude was shown to be approximately 4, so that the decay is very rapid. Very precise figures could not be given because of the complexity of the phenomenon, but it was shown that the mathematical formulæ were justified only on the assumption of no bottom current; the alternative of finite bottom current would require unduly large current velocities. The decay factor corresponds to a coefficient of eddy viscosity of about 1,300 C.G.S. units.

The relation between wind velocity and elevation, with the damping factor of 4, with certain assumptions as to the effective length of channel over which it operated, gave a stress coefficient of 0·0023 C.G.S. units. This is in good agreement with values obtained by other investigators, and showed that the various results derived from the investigation were in conformity with one another. The need for caution in deducing constants from observations uncorrected for all possible oscillatory causes was fully evident.

There was unfortunately very little opportunity for discussion.

THE KAURI TREE IN NEW ZEALAND

AN article dealing with the controversy over the question of the preservation of the famous kauri tree of New Zealand, with particular reference to the treatment and control of Waipoua Forest, was published in *Nature* of January 10, 1948. The article ended on an optimistic note, as it was felt that it should not be difficult to reach agreement. Unfortunately, that agreement has not been reached, mainly as one side feels unable to accept any compromise and appears convinced that nothing short of constituting the whole 40,000 acres a national park of the type in which nothing may ever be touched would meet requirements.

The latest development is the private publication by Mr. W. R. McGregor of an attractive booklet on the Waipoua Kauri Forest*. In producing this account, Mr. McGregor has done a real service to the wide public in New Zealand and the world over that is interested in the preservation of the best examples of natural vegetation still available for the enjoyment and study of future generations. He has a ready pen, and his descriptions reveal a deep love of the wild forest and an almost fanatic desire to exclude any activity in or near it that may threaten its wildness and solitude. The book is, moreover, profusely and excellently illustrated with fifty-six photographs. No attempt is made to disguise the fact that the author regards the State Forest Service as 'Enemy No. 1'. Indeed, perusal of the book leaves one with the impression that the object of its publication is to try to win popular support for bringing pressure to bear on the Government to withdraw the forest completely from control by the Forest Service and to constitute the whole of it a national park under some other authority on the lines adopted in Canada and the United States. This attitude leads to various charges against the Forest Service which one is reluctant to accept literally, and which, indeed, would be indignantly rebutted by the professional forester the world over.

Like any other Government Department, the Forest Department is the servant of the State, responsible for carrying out the policy of its Government, and Mr. McGregor is clearly on firmer ground when he charges (p. 11) the New Zealand public with "complete failure to develop a forest policy adequate to the needs of this country". It is rightly pointed out that the will of the people should determine the use of public land, and the reasons are marshalled why this particular area should be reserved, not for commercial forestry but as a strict Nature reserve in which no human interference with the natural processes of growth, decay and replacement should be permitted.

The reader is also reminded that ever since the original reservation of Waipoua in 1885 there have been various clear indications that those in responsible positions have viewed the forest as such a reserve. Thus Massey declined to sanction the construction of the public road which now traverses the forest, and, even when in 1926 it was built, the then Prime Minister gave assurances that timber would not be cut, and that the object of the road was only to give access for the public to see the kauri.

We understand that even the much maligned Forest Service has agreed that selected areas of the best kauri-bearing forest, as well as a strip all along the highway and individual trees of outstanding interest, should be excluded from forest management; and the real issue seems to be that of the precise extent of the desired Nature reserve. Mr. McGregor claims that the whole forest (about 40,000 acres, 27,600 being under forest) must be constituted a complete Nature sanctuary to safeguard the kauri, and he will contemplate no compromise. He gives no grounds to substantiate this claim except in the vaguest terms, and intense distrust of the Forest Service seems his strongest argument. Some of these charges are patently biased, while the pen-picture of the managed forest (p. 78) reveals a surprising ignorance of modern forestry objectives and practices.

The constitution of large national parks by Canada and the United States is quoted as a precedent to be followed, and it is urged that New Zealand should constitute such a park to save for future generations the last virgin kauri forest of New Zealand. The former countries have, indeed, many millions of acres of national parks, much of them under forest, in which no fellings are allowed (except for insect-infested or fungus-attacked trees); but they also still have vast extents of productive forests, so that the position is entirely different. The Waipoua proposition, however, clearly needs careful examination, action being stayed in the meantime to leave all possibilities open. The thesis is readily acceptable that though the kauri itself is the outstanding species to be preserved, it is unlikely that this aim can be achieved without equally protecting the native vegetation types with which the kauri is associated, particularly as knowledge of their life-history is still extremely slight. Clearly the areas selected for the preservation of the existing giant kauri should be of such extent as to include adequate samples of the other natural forest communities, some of which may be found to alternate in time with those in which kauri is now present. It can also be accepted that the amount of timber which could be obtained from Waipoua is not of great importance, either as a contribution to the total supply or specifically as special-purpose timber.

It may well be decided that to guarantee the safety of the kauri and preserve the associated vegetation it is not necessary to withdraw 40,000 acres from timber production; but early and full examination of the whole matter by a fully representative committee or commission is urgently needed. If, on the basis of its report, the country, through its elected representatives, decides in favour of the Nature reserve or national park project for a part or the whole of the forest, there should be no further hesitation in declaring that to be the decision, and so end the controversy. It may be instructive to note the action which has been taken by the State of California to preserve the redwoods along the comparatively new Redwood Highway, where relatively small blocks of forest, from a few to a few hundred acres, have been reserved or acquired in one way or another and constituted State parks. The species is adequately preserved in the surrounding forests which are under felling and regeneration by the State or private owners, the special steps being required only for the preservation of outstandingly fine trees or groves easy of access to the public.

There is also an interesting comparison to be made with the proposal now before the public in Great Britain that the State foresters should be empowered to take appropriate action to preserve and ensure the perpetuation of the oldest parts of the New Forest. These remnants are in real danger of disappearance because the requisite powers are at present lacking. In undertaking this task, the Forestry Commission would have no prospect of any financial return but only of additional expenditure.

H. G. Champion

OBITUARIES

Mr. J. H. Coste

JOHN HENRY COSTE died on January 3 at his home at Smallfield, near Horley, Surrey, in his seventy-eighth year. His death further reduces the dwindling number of old Finsbury Technical College students, for it was at this College during 1888–91 that he received, under Meldola, scientific training which served him in such good stead for a long and most useful life. He obtained his first appointment under John Augustus Voelcker, and three years later joined the staff of the Chemical and Gas Testing Department of the London County Council; he remained in this service until his retirement in 1936. His ability was soon recognized, and in 1908 he was appointed chief assistant and in 1912 promoted to the position which is now designated Chemist-in-Chief, Public Health Department. He was always a keen experimenter, and scientific literature, mainly *The Analyst* and the *Journal of the Society of Chemical Industry*, contains no less than fifty papers of which he was either the author or part author. A perusal of these contributions shows him to have been a very versatile worker, for the subjects include petroleum, paint, water, air, milk, coal, sewage, etc., and in addition he was the author of one and part author of two books, on the calorific power of gas, the chemistry of paint pigments and on fuel.

Necessarily the field of his activities was very wide, as covering the scientific aspect of all the work of the premier local government authority in the world. In his later years his chief interests centred in two matters intimately connected with public health, namely, atmospheric pollution and sewage treatment. He was a member of the original research committee of the Meteorological Office on the former subject, that work being transferred later to the Department of Scientific and Industrial Research. After his retirement he was still active in this field right up to the time of his sudden death. Naturally, too, as a successor to the pioneers W. J. Dibdin and Frank Clowes as the senior chemist in the London County Council's service, he was intimately concerned with the sewage disposal problem, and did original work on this subject and its related one of water pollution.

Mr. Coste was a fellow of the Royal Institute of Chemistry and of the Institute of Physics, and served for periods on the council of the former and also on that of the Society of Public Analysts.

His nature was kindly and he was always approachable and willing to help in any problem, official or personal, which was put to him. His sudden passing is a great loss to the many who were privileged to be counted among his friends. C. J. REGAN

Prof. Egon von Schweidler

EGON RITTER VON SCHWEIDLER, formerly professor of physics in the University of Vienna, died on February 12, 1948, in his country home near Salzburg. His death has not hitherto been recorded in *Nature*.

Schweidler's name is familiar to all workers in radioactivity as the co-author of a manual of radioactivity which surpasses the well-known French and English standard works in this field by the range it covers and the completeness of its documentation; the two editions of 1916 and 1927 have been most valuable to generations of physicists and chemists. It was written in collaboration with St. Meyer, with whom Schweidler's name is linked also in numerous experimental papers on radioactivity. Another field in which he worked as an experimental physicist and was an acknowledged authority is atmospheric electricity.

It was, however, a contribution to theoretical physics by which Schweidler exerted the strongest influence on the development of science. At the International Congress on Radiology held in Liège in 1905, he read a paper in which he gave the statistical interpretation of Rutherford and Soddy's law of radioactive disintegration. He showed that the statement that, per unit of time, it is always the same fraction of a radioactive substance which disintegrates, can be true only if the law of large numbers makes its levelling effect felt and obscures the deviations; but these must become obvious as soon as the number of atoms under observation is reduced sufficiently. These 'Schweidler fluctuations' were soon verified by experiment, and thus the chance character of the process of disintegration directly demonstrated.

This erratic behaviour of single atoms seemed in 1905 to be something completely out of step with the rest of physics and confined to radioactive disintegration. However, in 1917 Einstein used an analogous interpretation of the emission of light from an excited atom, and it is well known what a predominant role statistical interpretations now take in quantum mechanics. The credit must go to Schweidler, however, for having recognized the first case in a fundamental paper which, in his history of physics, von Laue calls "a step forward of incalculable importance".

Schweidler was born in Vienna on February 10, 1873; he was a student, a lecturer, and an assistant professor there before he was called to the chair of physics in Innsbruck. This he occupied from 1911 until 1926, when he returned to Vienna as director of one of the physics institutes there. This position he held until his retirement in 1939. He was a member of the Vienna Academy of Sciences and for several years also general secretary and vice-president.

The atomistic school of Vienna, famous for such names as Loschmidt and Boltzmann, has lost in Schweidler another worthy representative.

F. A. PANETH

Mr. G. P. Farran

GEORGE PHILIP FARRAN, who died at his home at Templeogue, Co. Dublin, on January 5 at the age of seventy-two, was connected for nearly fifty years with the Fisheries Branch of the Department of Agriculture there. After a distinguished career at Trinity College, Dublin, he joined the small group of scientific men working, under the late Ernest W. L. Holt, on fishery and marine biological problems in Ireland; and afterwards, in 1900, he entered the service of the Department of Agriculture and Technical Instruction as a naturalist. In 1938 he was promoted to chief inspector of fisheries, a post from which he retired in 1946.

Farran's early papers had ranged over a wide field; but later in life he more or less restricted his activities to the study of planktonic organisms, particularly copepods, and the Irish herrings. As a planktologist he was a recognized authority. For a period of more than twenty-five years he represented Ireland at the annual meetings of the International Council for the Exploration of the Sea. He was elected to membership of the Royal Irish Academy in 1912. A year ago he was elected an honorary member of the Challenger Society for his work in marine biology, and shortly before his death he was preparing to attend one of the joint meetings of the Society in London.

We regret to announce the following deaths:

Mr. W. C. Chesterman, O.B.E., assistant secretary of the University Grants Committee, on January 29, aged fifty-nine.

Dr. F. H. A. Marshall, C.B.E., F.R.S., formerly reader in agricultural physiology in the University of Cambridge, on February 5, aged seventy.

NEWS and VIEWS

Physics at the National Research Council, Canada:

Dr. G. Herzberg

Dr. Gerhard Herzberg has been appointed director, Division of Physics, National Research Council, Canada, in succession to Dr. R. W. Boyle, who retired in October 1948. Dr. Herzberg is a Canadian citizen who has been on the staff of the Division of Physics for some months as a principal research officer, having gone to this post from the Yerkes Observatory, University of Chicago, where he had been professor of spectroscopy for nearly three years. During the preceding ten years, he was research professor of physics at the University of Saskatchewan, Saskatoon, Sask. Before that, he had worked in Germany at Darmstadt and Göttingen, and in the University of Bristol. Dr. Herzberg is a leading authority on spectroscopy and molecular structure, and is the author of three standard text-books and numerous scientific papers. At Saskatoon he established a spectroscopy laboratory for graduate research and thus greatly strengthened the graduate school in physics and chemistry. He and his co-workers made important contributions to interpretation of data on spectral lines of distant stars and of comets. These investigations led up to his work at the Yerkes Observatory, where he built the world's longest multiple optical path (5,000 m. at atmospheric pressure) for the study of planetary atmospheres and to gain information on molecular structure. Using this equipment, he carried out important work on the infra-red absorption spectra of hydrogen, which has made it possible to detect hydrogen in planetary atmospheres. Dr. Herzberg will continue his varied researches in his new post.

Dr. L. E. Howlett, M.B.E.

Dr. Leslie E. Howlett has been promoted to be associate director of the Division of Physics, National Research Council, Canada. Graduating in mathematics and physics in the University of British Columbia in 1927, he went to the University of Toronto as a research fellow, proceeding eventually to McGill University for his doctorate. Since 1931 he has been on the staff of the National Research Council in charge of the optics section. During the War he aided in the development of the optical instrument industry, for which he was awarded the M.B.E. in 1943. He served as chief scientific liaison officer in London and later in Washington. Since July 1948 he has been assistant director of the Division, and his advancement to the post of associate director is a tribute to his success in the organisation and management duties entrusted to him.

Another Big Sunspot

Misty or foggy conditions in Britain on February 4 made it possible to see with the naked eye a big group of sunspots that had grown rapidly after February 1. Another factor which contributed to its 'discovery' by many members of the general public was the favourable position of the spot group near the centre of the disk. At central meridian passage on February 5·4, the group passed within 2° of the centre of the disk, and its area was then greater than 2,000 millionths or 1/500 part of the sun's hemisphere. Although in size the present sunspot was only about half that of the four giant spots seen in 1946–47, it has attracted more general interest, because of the recent atmospheric conditions for its easy visibility, and also because of the earlier big spot group of comparable size a fortnight earlier, with the associated auroral display on January 24–25 (see *Nature*, February 5, p. 203). Observers of the setting sun, seen through the London mist on February 4, could also pick out with the unaided eye two other spots.

Government Expenditure on Universities in England

In a written Parliamentary reply to Mr. Kenneth Lindsay on January 18, Sir Stafford Cripps, the Chancellor of the Exchequer, said that the non-recurrent payments to the Universities in England during the years 1945–49 were as follows: 1945–46, £620,895; 1946–47, £566,996; 1947–48, £1,920,508; 1948–49 (to January 14, 1949), £1,980,686. The principal projects covered by these grants are the purchase of sites and buildings, the erection of new buildings (including new teaching blocks for science and technology and halls of residence) and the provision of new equipment. The amounts paid to individual institutions have varied according to the opportunities for building and the degree of expansion of numbers in an individual centre. Sums in excess of £200,000 are listed as follows: University of London, £1,283,348; University of Durham, £504,011; University of Nottingham, £319,083; University of Birmingham, £292,485; University of Leeds, £270,418; University College of Hull, £240,813; University of Bristol, £230,521; University of Oxford, £217,507; University of Reading, £215,645; University College, Leicester, £213,902.

The Oil Position in 1951

Middle East oil is again prominent in the American Technical Press, this time in a paper entitled "The Place Middle East Oil will occupy in World Markets", read by C. J. Bauer, of the Standard Oil Company, New Jersey, at the annual meeting for 1948 of the American Institute of Mining and Metallurgical Engineers. As is now generally appreciated, the function of Middle East oil, once pipe-lines to the Mediterranean are completed, will be to relieve the strain on western hemisphere petroleum resources, that is to say, the United States and Caribbean region, from which at present most of West European oil is derived. The year 1951 appears to be the crucial factor; by then it is anticipated that the annual world demand will be about 140 thousand million Imperial gallons. This will require new capital investment in the industry of £2,500 million before that year. Consumption is estimated by 1951 in the ratio of 6·3 million barrels per day for the United States as against 4·4 million for the rest of the world; in other words, there should be more petrol available for the so-called Marshall Plan countries which, unhappily, at present constitute the largest petroleum-deficient area in the world. By the same tokens, it is anticipated that the United States will practically cease to export oil and oil products to Europe by 1951, the Caribbean and Middle East regions then being the main sources of supply for Europe. The author stresses the recognition of the four great oil regions of the world, East Mediterranean basin, the Caribbean basin, the Far East basin and the North Polar basin; nowhere else are future oil supplies of magnitude likely to be found. Taking the long view, the bulk of Middle East supplies are destined for Europe; the Caribbean will furnish the major part of oil supplies to the western hemisphere; Asia, Australia and New Zealand will draw mainly on the Far East basin (when rehabilitated); and the North Polar basin, not yet in production, is destined to supply both North America and Russia. This is a far-sighted review of the world's oil situation, and it is presented in a form which, aided by extremely informative diagrams, is readily understandable to the layman. Copies of the paper may be obtained on application to the Anglo-American Oil Company, London.

Science Co-operation Office, Middle East

The Science Co-operation Office, Middle East, of Unesco, in Cairo publishes a list of the scientific papers received at the Office; List No. 2 includes the titles of papers received during March 1–July 31, 1948, in addition to those received from January 1, 1947, and given in the previous list. The titles are again arranged under fourteen headings, the bulk of the entries falling under mathematics (2 pages), chemistry (2), geology and geophysics (2), zoology (2), medical sciences (27), engineering sciences (3), and agricultural science (5). Those under medical sciences are further subdivided and fall chiefly under physiology, biochemistry and pharmacology (3–4 pages), medical microbiology and hygiene, parasitology (4), internal medicine and surgery (5) and dermatology and venereology (2). A list of periodicals and serials normally received, arranged by countries, is also included.

A New Mechano-Electrical Transducer

Recently the U.S. National Bureau of Standards has announced the development by W. A. Wildhack of a new highly sensitive mechano-electrical transducer in which small mechanical displacements are transformed into large changes of resistance, current or voltage. Displacements as small as 10^{-5} in. can be measured directly without the use of auxiliary electrical amplifying devices. A nickel-alloy wire, chosen because of its high resistivity and small change in mechanical properties with temperature, is coiled into a close helical or conical spring such that the initial tension varies along its length. Thus, when the ends of the spring are pulled apart, the turns separate one by one, the electrical resistance varying from that with the spring completely closed (approximately a cylindrical metal tube) to that with the spring entirely open (total uncoiled length of wire). The spring transducer is a very sensitive means of conversion, for any small stretching of the spring results in a correspondingly large change in resistance. Used in combination with other transducers, or in a four-arm bridge of which each arm is a spring-transducer, the new transducer should have many scientific and industrial applications.

Wild Birds and the Land

Increasing interest in wild bird life, both from the economic and natural history points of view, has led to the publication of a bulletin under the above title by the Ministry of Agriculture and Fisheries (H.M. Stationery Office. 2*s.* 6*d.*). The bulletin has been prepared by F. Howard Lancum, advisory ornithologist to the Ministry, who has brought together a large collection of fine photographs by some of Britain's leading bird photographers. Each of the fifty species illustrated is accompanied by a note on its physical characteristics and behaviour patterns, along with a statement on its economic significance where this is known. A concluding chapter on the use and method of constructing nest-boxes and bird-tables adds to the value of a publication which could only be published at its present price on behalf of a Government department.

Fossils at the British Museum (Natural History)

The Department of Geology in the British Museum (Natural History) has now resumed publication of the interesting and informative series of guide-books that were issued at intervals in pre-war years. The exhibition galleries were largely dismantled at the beginning of the War, and the Museum itself was afterwards severely damaged by enemy action. The re-assembling of the exhibits, and the execution of plans for re-arrangement already made in 1938, will require a long time to complete. Meanwhile, as a first step, an exhibit has been set out which is intended to serve as an introduction to the study of fossils. The fossils are stratigraphically arranged, and epitomize the succession of life through geological time. The exhibit also shows how fossils reflect past conditions, and suggests how the various forms of life developed and reacted one on another in diverse environmental associations. The new guide-book, which is primarily intended to be used in conjunction with the exhibit, is entitled "The Succession of Life through Geological Time", the authors being K. P. Oakley and Helen M. Muir-Wood. It is priced at 2*s.* 6*d.*, consists of 92 pages, and includes an adequate number of well-executed black-and-white drawings and four palæogeographical maps. There is also an attractive colour plate, figuring, in natural surroundings, a reconstruction of one of the first birds, *Archæopteryx*, the unique specimen of which, from the Jurassic Limestone of Bavaria, is on exhibit in the Museum. Allowing for the increased costs of production, the price is very modest, and the guide might well prove useful as a supplement to the more orthodox elementary text-books of geology.

Bedfordshire Natural History Society and Field Club

The original Bedfordshire Natural History Society and Field Club was founded in 1875 with fifty-nine members, and its proceedings were published in three volumes covering the years 1875–84. The Society ceased to exist about ten years later, and no record exists to show why a Society that held such promise should have ceased to function after such a short life. In October 1946 a new county Society was formed under the old name. The reports for 1946 and 1947 indicate that the Society has made a good start under Mr. Oliver Pike's presidency and should soon gain its rightful place among similar county societies in Britain. Copies of the Society's journals may be obtained from 11 The Avenue, Flitwick, Bedfordshire.

Breeding of Locusts for Research and Instruction

THE supply of living animals for both teaching and research purposes is a perennial problem for zoological laboratories. The new insecticides are partly responsible for the difficulty which has occurred in recent years in obtaining adequate supplies of cockroaches. For many purposes the locust can take the place of the cockroach, and it has the advantages of being larger, easy to rear in laboratory conditions and, for such a large animal, it has a very rapid life-cycle; the whole life-cycle takes about seven weeks, and only about half that time is required from hatching to the emergence of the adults. Instructions for the breeding and rearing of locusts have now been prepared by the Anti-Locust Research Centre, and copies can be obtained from the Director of the Centre, British Museum (Natural History), London, S.W.7. The Centre is not prepared to sell locusts to anyone, but it will supply them free for certain research projects and, so far as possible, for starting stocks for teaching purposes; adults for class dissection will not be sent.

The Physical Society: Annual Exhibition

THE Physical Society's Annual Exhibition of Scientific Instruments and Apparatus will be held during April 5–8, 1949, in the Physics Department of the Imperial College of Science and Technology, South Kensington. The sessions during which the Exhibition will be open are: April 5, 2–9 p.m.; April 6, 10 a.m.–1 p.m., 2–9 p.m.; April 7 and 8, 10 a.m.–1 p.m., 2–7 p.m. During the Exhibition the following discourses will be delivered: "Some Problems of Wave Diffraction in the Ionosphere", by Mr. J. A. Ratcliffe; "Some Modern Aspects of Scientific Instruments", by Mr. A. J. Philpot; "A Review of the Methods and Instruments used in Energy Measurements of Particles in Atomic Nuclei", by Prof. O. R. Frisch. A film on the liquid idophor or teleidoscope will be shown. The Exhibition will also display entries for the craftsmanship and draughtsmanship competition, which is being revived after a lapse during the war years. This competition is organised to encourage and give recognition to skill and ability in craftsmanship and draughtsmanship among apprentices and learners in the instrument-making industry, and a large number of firms and technical institutions is supporting it. The prize-winning entries will afterwards be shown in the Science Museum at South Kensington.

Management Bulletin

FROM December 1948 the British Institute of Management has been issuing to members and subscribers a *Management Bulletin* concerned with events in the management field as a whole. The first issue includes a list of forthcoming events as well as papers arranged by the Institute for February–May, 1949, with brief notes on the activities of the education department, examinations department and the information and research department, and a list of recent additions to the library. Suggestions and criticisms with regard to the scope and utility of the *Bulletin* are invited.

Seventh Pacific Science Congress

THE Seventh Pacific Science Congress (see *Nature*, September 11, p. 409) is now in session in New Zealand. Thirty countries are participating, and of these the seventy-one United States representatives form a particularly large delegation. These American men of science are representing not only the United States but also the dependent territories, such as the Pacific Islands and Honolulu, and the occupation authorities in Japan. British and American civil air-lines and also the United States Military Air Transport Service have made special arrangements to fly these American delegates from their respective scattered locations to New Zealand. The Royal Society has sent a delegation of six to the Congress (*Nature*, January 1, p. 17).

Announcements

PROF. PIERRE-PAUL GRASSE has been elected a member of the Section of Anatomy and Zoology of the Paris Academy of Sciences, in succession to Dr. Robert Courrier, who has become one of the permanent secretaries of the Academy.

THE Institute of Metals Medal (in platinum) for 1949 of the Institute of Metals has been awarded to Dr. William Hume-Rothery, lecturer in metallurgical chemistry in the University of Oxford, in recognition of his outstanding contributions to the science of non-ferrous metallurgy.

PROF. F. F. NORD, of the Department of Organic Chemistry, Fordham University, New York, has been awarded the 1949 Carl Neuberg Medal of the American Society of European Chemists and Pharmacists.

PROF. K. S. DODDS, head of the Department of Botany and Genetics at the Imperial College of Tropical Agriculture, Trinidad, has been appointed principal scientific officer of the Empire Potato Collection, Commonwealth Bureau of Genetics, Cambridge.

MR. W. K. B. MARSHALL has been appointed assistant director of research of the British Welding Research Association. Mr. Marshall is well known for his work on light alloy and stainless steel welding, and in his new position he will pay particular attention to non-ferrous welding research.

THE officers for 1949 of the Nairobi Scientific and Philosophical Society (see *Nature*, October 23, p. 647) are: *President*, V. A. Beckley; *Vice-Presidents*, Dr. B. A. Keen, Dr. R. M. Dowdeswell and H. E. Watson.

THE Institute of Navigation has arranged a symposium on "Operational Aspects of Marine Radar", to be held at the Royal Geographical Society on February 18, at 2 p.m., under the chairmanship of Sir Robert Watson-Watt. Papers to be presented include two from the U.S. Institute of Navigation. The meeting is open to non-members.

THE W. H. A. Robertson Medal and Premium will be awarded annually by the Institute of Metals to the author or authors of the best paper contributed to the *Journal of the Institute of Metals* on engineering aspects of non-ferrous metallurgy. For the first award, papers published in the Institute's *Journal* from March 1948 to August 1949, inclusive, will be considered.

Influence of Cosmic Radiation on Experimental Tuberculosis

THE results of two series of experiments on the action of cosmic radiation on experimental tuberculosis in mice are reported below. In the first series, eighty mice were injected intravenously in Leyden (sea-level) with 1 mgm. of tubercle bacilli and transported four days later to the Jungfraujoch (3,457 m.).

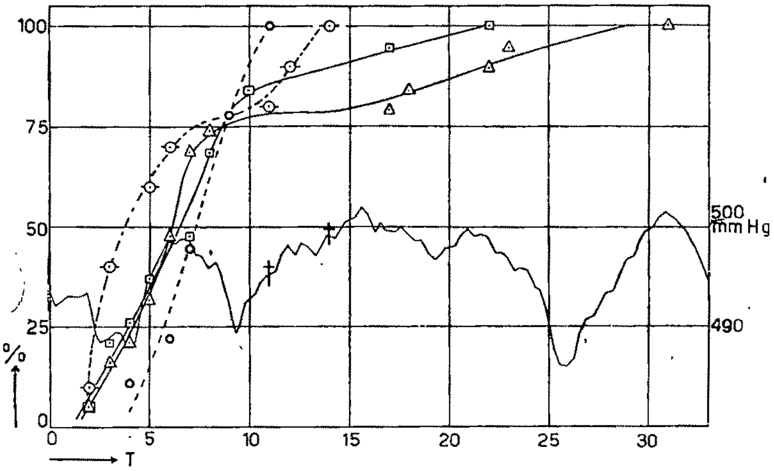

Fig. 1. Mortality curve. *T*, time in days after treatment; △, mice kept in daylight; □, mice screened from cosmic radiation; ○, mice exposed to direct cosmic radiation; —○—, mice exposed to cosmic radiation with 2 cm. of lead

One group was exposed to the direct action of cosmic radiation, a second group was placed under 2 cm. of lead, which gave the maximum intensity of showers, a third group was screened from cosmic radiation, and a fourth group was exposed to daylight and ultraviolet light down to 3,300 A., being thus subjected only to the hard component of the cosmic radiation. The first three groups were placed in a room without daylight, illuminated by a 40-watt electric lamp.

Fig. 1 represents the cumulative mortality curve. The beneficial effect of screening from cosmic radiation can be seen by comparing the curves for mice exposed to cosmic radiation with that for mice screened from cosmic radiation. The beneficial effect of daylight and ultra-violet light can be seen by comparing the curve for mice exposed to daylight with that for mice exposed to cosmic radiation, and that for mice screened from cosmic radiation. By statistical methods, it has been shown that there is no significant difference between the mean times of survival, but there is a significant variation from uniformity of mortality among groups treated alike ($P < 0 \cdot 001$). The different groups of mice are thus not from the same population. The weight of the mice exposed to cosmic radiation with and without absorber is significantly higher than that of the mice screened from cosmic radiation. The last curve has the same form as that of the mice exposed to daylight. Two of the mice exposed to cosmic radiation with 2 cm. of lead developed severe intestinal hæmorrhage; it will be seen from Fig. 1 that these mice died when the barometric pressure was increasing. The mice exposed to direct cosmic radiation showed tremblings during the last weeks, one of them dying with extreme abdominal ascites. It is important to note that three of the mice exposed to cosmic radiation with 2 cm. of lead absorber had only a few tubercles in the lung, whereas all the other mice showed severe lung tuberculosis.

In the second series, sixty mice were injected intravenously with 0·7 mgm. of tubercle bacilli at the Jungfraujoch (3,457 m.). The tubercle bacilli were thus immediately in contact with low oxygen tension in the lung (60 mm. mercury). It has been shown independently by Rich and Follis[1] and Ong, den Dooren de Jong and Schornagel[2] that the histological lesions are markedly inhibited and the mean time of survival is significantly prolonged, when tuberculous mice are kept in an oxygen concentration below 10 vol. per cent. In the early stages of dying, only a few tubercles were found in the lung, but there were tuberculous lesions in the spleen, kidney and liver. In the later stages, we observed severe lung tuberculosis with small or no lesions in the organs, and in these cases there was anoxia and thus the oxygen supply in the body tissues was insufficient. This diminished the lesions in the organs.

There were four groups in the second series: mice kept in artificial light screened from cosmic radiation, mice kept in artificial light exposed to direct action of cosmic radiation, mice kept in artificial light placed under 2 cm. and 10 cm. of lead. As in the first series, we observed hæmorrhages among the mice exposed to cosmic radiation. The hæmorrhages were from the genital organs, mouth, intestines and rupture of the spleen. Three of these mice died during the ascending phase of the barometric pressure and two in the descending phase. As the intensity of the cosmic radiation changes with the barometric pressure, and as none of the mice exposed to the same barometric pressure but screened from cosmic radiation showed any hæmorrhage, we conclude that the hæmorrhage is caused by the variation of intensity of the cosmic radiation.

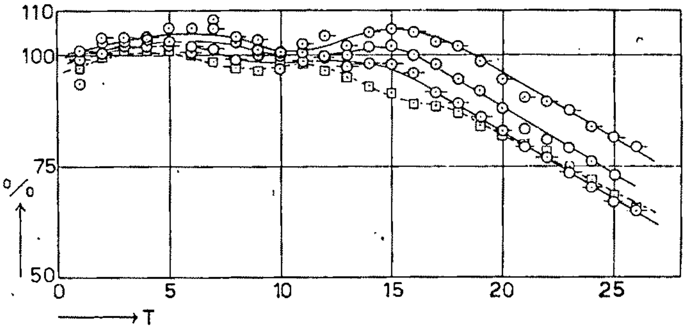

Fig. 2. Weight curve. *T*, time in days after injection. □, Mice screened from cosmic radiation; ⊙, mice exposed to direct cosmic radiation; ⊙—, mice exposed to cosmic radiation with 2 cm. of lead; —⊙—, mice exposed to cosmic radiation with 10 cm. of lead

There is no great difference in the form of the mortality curves of the four groups of mice. Statistical methods show no significant difference between the mean lives, but show significant variation in mortality among groups treated alike. We also conclude that the groups of mice are not from the same population.

As in the first series, the weight of the mice exposed to cosmic radiation is significantly higher than that of the mice screened from cosmic radiation (Fig. 2). Fig. 2 shows that the more the mice were exposed to the soft component and the showers of cosmic radiation, the more the loss of weight is retarded.

I am indebted to Prof. J. Clay for discussions on cosmic radiation; to Prof. D. Chalonge and Mr. F. Egger for determining the transmission spectra for ultra-violet light; to Mr. E. van der Laan for discussing statistical methods; to Dr. W. Mörikofer for the records of barometric pressure at the Jungfraujoch; also to Messrs. U. Camerini, J. A. Gay, D. Ritson and M. A. Roberts for assistance in the cosmic radiation experiments. This research was rendered possible by a grant from the Nederlandsche Organisatie voor Zuiver-Wetenschappelijk Onderzoek.

Cross-section for the Disintegration of the Deuteron by 2·76 MeV. γ-Rays

SINCE our recent communication[1], calibrated sources of radiosodium have become available. In view of the high value for the cross-section for photodisintegration of deuterium with radiothorium γ-rays, we decided to repeat our measurements with a radiosodium source. At the same time, several improvements in the apparatus were made; a spherical electrode instead of a cylinder now defines the sensitive volume of the ionization chamber; this avoids the error due to low field at the corners, and reduces the γ-ray background. This improvement, and a slight reduction in valve noise, enable higher counting-rates to be used, and enable pulses of 150-keV. energy to be counted before γ-ray and noise background becomes troublesome. The shielding due to positive ions does not reduce any pulses below this energy, and the correction for this effect is zero; the wall-effect correction is also reduced (4 per cent for radiothorium source, 6 per cent for radiosodium source).

The deuterium concentration was measured at Metropolitan-Vickers Electrical Co., Ltd., with a mass spectrometer which admitted the gas through a needle valve. This obviated the palladium leak separation factor, and gave a result for the deuterium content of the samples 4 per cent higher than that obtained previously (99·2 ± 0·5 per cent deuterium). This agrees with the expected output of our electrolysis plant.

As a check upon the correct operation of the counter, the pulse-height distribution was plotted with a single-channel kick-sorter. The observed distribution was slightly wider than the theoretical distribution. This can be accounted for by positive ion effects and the change in zero due to γ-ray background. When corrections have been applied for these, the ratio of the electric to magnetic photo-effect can be deduced, for the pulse-height distribution can be related to the angular distribution by the principle of conservation of momentum. The results thus obtained are in agreement with those obtained recently in Copenhagen[2] and with other results[3].

A further check is afforded by the ratio of the pulse-heights for disintegration by radiosodium and radiothorium rays. This agrees with the expected value, 1·32, different determinations giving 1·30, 1·31, 1·32, 1·37. The radiothorium source was calibrated as before, using Ricoux's result[4]. An alternative method using the less accurate results of Shenstone and Schlundt[5] would yield a 3 per cent higher value for the cross-section; so also would a method based on the total ionization from radiothorium γ-rays[6], coupled with a knowledge of the γ-ray energies and relative intensities[7]. An aliquot from the sodium source was calibrated at the Atomic Energy Research Establishment, Harwell, by Mr. Putman and Mr. Willment, using a β-γ-coincidence method[8]. The β-spectrum is single[9] and is followed by a 2·76-MeV. and a 1·38-MeV. γ-ray in cascade for every disintegration. There is not more than 1 per cent of β-rays of 2·76 MeV. or higher energy[10]. An intercomparison between their calibration and results using a small graphite-walled ionization chamber has been made by Gray[6], and they agree to within 2 per cent. Altogether, the radiosodium calibration seems to us less subject to doubt than the radiothorium calibration.

Any γ-rays from forbidden lines (RdTh 3·2 MeV. and Na^{24} 4·14 MeV.) would produce more energetic photoprotons. These have been looked for, and upper limits of one part in one thousand and one part in ten thousand respectively can be assigned to these transitions. The decay period of radiosodium has been redetermined as 14·90 ± 0·02 hr.[11].

The results we now present are the mean of five independent measurements; for each filling, a determination was made for both radiosodium and radiothorium; the radiothorium determinations agree within 1½ per cent, which is better than in the case of the sodium determinations, since it includes only the errors in counting, distance measurement and pressure measurement. As a different sodium source was used for each determination, the calibration errors enter into the consistency of the sodium determinations.

Radiothorium cross-section	14·8 ± 1·0
Radiosodium ,, ,,	15·6 ± 1·0
Ratio	1·05 ± 0·08

The theoretical values for the radiosodium cross-section have been kindly sent to us by Prof. Hulthén. The ratio $\sigma_{Na}/\sigma_{RdTh} = 1{\cdot}21$ for a meson mass 296, and 1·22 for meson mass 197. Thus the observed ratio constitutes a certain discrepancy.

Since these measurements were made, a new value for the binding energy of deuterium has been published[12]. The cross-sections for this value (2·237 MeV.) of the binding energy are lower by about 10 per cent.

Detailed results will be published elsewhere in due course.

We have to thank Mr. K. Wood, of Metropolitan-Vickers Electrical Co., Ltd., for analysing the deuterium ; Messrs. J. L. Putman and R. Willment, of the Atomic Energy Research Establishment, Harwell, for the calibration of the sodium source ; Mr. G. R. Bishop, for his help with the measurements ; and Lord Cherwell, for extending to us the facilities of this Laboratory.

The Primary Soft Component of Cosmic Radiation

In a recent communication, Rossi[1] analysed burst measurements of Hulsizer[2] and concluded that if a primary soft component exists at all, it constitutes not more than a few per cent of the total primary intensity. In our opinion, Rossi's numerical interpretation of Hulsizer's results is erroneous.

Bursts were observed by Hulsizer containing a minimum of eighty ionizing particles passing through the burst chamber. The cross-section of the burst chamber was 50 cm.^{2} ; it was covered by 2·5 cm. of lead. At a height 0·5 cascade units under the top of the atmosphere, 300 bursts per hour exceeding the minimum size were observed. These bursts were interpreted in the following way : (1) it was assumed that the absorption of any primary spectrum through the atmosphere above the chamber was negligible ; (2) it was assumed that electrons of 4,500 MeV. can give rise to bursts of eighty particles ; (3) it was assumed that half the bursts are not caused by cascade showers but by heavily ionizing particles.

Thus an upper limit for the number of electrons with energies exceeding 4,500 MeV. was derived. Comparison with the total number of incident particles led Rossi to conclude that "not more than 1 per cent of the primaries are electrons with energies exceeding 4,500 MeV.". In our opinion, the calculation requires modification.

(1) The absorption law of a power spectrum of electrons is well known ; given an incident spectrum,

$$S(E;\ 0) = \frac{A}{E^{\gamma+1}}, \tag{1}$$

at a depth of ζ cascade units, we have,

$$S(E;\ \zeta) = \{M(\gamma) \exp\left(-a_1(\gamma)\zeta\right) + N(\gamma) \exp\left(-a_2(\gamma)\zeta\right)\} S(E, 0) \tag{2}$$

(see for details, for example, Jánossy, "Cosmic Rays", p. 237).

With $\gamma = 1\cdot 7,\ \zeta = 0\cdot 5,$

we find

$$S(E_1\ \zeta)/S(E_1\ 0) \sim 0\cdot 5.$$

Thus the primary component is reduced to half its intensity under $\zeta = 0\cdot 5$ (a fraction of this reduction is replaced by photons).

(2) An electron of 4,500 MeV. does not give rise to a shower of eighty particles. But, in any case, a large fraction of shower particles in lead have energies of a few MeV. only, and many of those will be lost by scattering. Thus it seems reasonable to assume that a shower which contains a total of, say, 160 particles, will just manage to produce 80 particles passing through the chamber.

Using the formalism of Bhabha and Chakrabarty, we find that a primary energy of about 20,000 MeV. is required to give rise to a burst of eighty particles in the burst chamber. Thus, accepting other details given by Rossi, we are led to conclude that not more than 2 per cent of the primary cosmic rays are electrons with energies exceeding 20,000 MeV.

If the cut-off of the power spectrum is taken to be at 2,000 MeV., the total number of electrons according to (1) must be less than

$$2 \text{ per cent} \left(\frac{20{,}000 \text{ MeV.}}{2{,}000 \text{ MeV.}}\right)^{1\cdot 7} = 100 \text{ per cent.}$$

Thus no significant upper limit for the strength of the primary component can be derived from Hulsizer's measurements.

I would not go so far as to suggest that Hulsizer's measurements *prove* the existence of a soft component, as there are many *ad hoc* ways of accounting for the experiments. I would like to emphasize, however, that there is to my knowledge no valid experimental evidence against the existence of a primary soft component ; while latitude effect and extensive air showers can most easily be accounted for in terms of a primary soft component forming a moderate fraction (say, 30 per cent) of the total primary intensity. General arguments supporting the existence of a primary soft component have been presented and discussed in detail by Ferretti[3].

L. Jánossy

School of Cosmic Physics,
Dublin Institute for Advanced Studies.

[1] Rossi, B., *Rev. Mod. Phys.*, **20**, 537 (1948).
[2] Hulsizer and Rossi, *Phys. Rev.*, **73**, 1402 (1948).
[3] Ferretti, B., *R. Acad. d'Italia*, 13, 1287 (1942).

We are glad that the critical remarks of Jánossy give us an occasion to reconsider the interpretation of our balloon experiments.

We have been aware of the fact that some of the figures quoted in our original paper are inaccurate. Indeed, in a paper presented by one of us at the Cosmic Ray Symposium held in Pasadena last June, a revised estimate of 10 BeV. was given for the minimum energy of an electron capable of producing the observed bursts[1]. We can, however, answer specifically Jánossy's remarks.

(1) Atmospheric absorption. Since our instrument is sensitive to electrons and photons alike, one has to consider the change in the total number of these particles and not that in the number of electrons alone. For vertical incidence and for a power spectrum with $\gamma = 1\cdot 7$, the reduction factor at a depth of 20 gm. cm.$^{-2}$ amounts to 0·7. However, we must consider that the quantity measured by our instrument is closer to the integrated rather than to the vertical intensity. For the integrated intensity the reduction factor is 0·44.

(2) Energy E_0 of an electron which produces a shower of 80 particles through our chamber. The calculations of Richards and Nordheim, which have

just been published[2], show that the proportion of low-energy electrons in a shower from lead is exceedingly large. Thus Jánossy's estimate of 50 per cent for the number of shower electrons which penetrate the chamber wall appears quite reasonable, even though the thickness of this wall is only 0·6 gm.cm.$^{-2}$. However, the production of electrons in the chamber wall by photons from the lead may appreciably reduce the effective absorption. If we do not take this last effect into account, and if we apply the results given by Bhabha and Chakrabarty in their most recent publication[3], we obtain for E_0 a value of 13·5 BeV. This value is arrived at by considering electrons which travel perpendicular to the chamber axis and which traverse on the average 2·8 cm. of lead thickness. Electrons arriving at an oblique angle traverse a greater thickness of lead, and their shower particles travel a longer path in the chamber. Both effects reduce the value of the electron energy corresponding to a given burst size. The correction to E_0 for the effect of oblique incidence is not easy to compute. At any rate, it appears as if Jánossy's estimate of 20 BeV. for E_0 may be excessive, and a value of 10 BeV. such as given at the Pasadena Symposium may represent a more likely estimate.

(3) Low-energy cut-off of the primary spectrum. Balloon experiments of Millikan, Neher and Pickering[4] by means of cosmic ray telescopes failed to reveal any change of the vertical intensity at latitudes greater than 45°. This places the cut-off energy at a value higher than 4 BeV., rather than at 2 BeV., as quoted by Jánossy. (At 45° the limiting energy corresponding to the Størmer cone is 3·8 BeV., that corresponding to Lemaître and Vallarta's main cone, 6 BeV.)

On the basis of the above considerations, one would obtain from our measurements an upper limit of about 11 per cent for the number of electrons in the primary radiation. However, we are very hesitant about this figure, especially because of the great uncertainty of the shower theory for heavy elements.

In conclusion, it is our present opinion that the question concerning the existence of electrons in the primary cosmic radiation is still open and can only be settled by further experiments. One of these experiments, directed at obtaining information as to relative contributions of electron showers and of nuclear interactions to the ionization bursts observed at high altitude under lead, is at present under way.

Theory of Superconductivity

IN two previous notes[1], Prof. Max Born and I have shown that one can obtain a theory of superconductivity by taking account of the fact that the interaction of the electrons with the ionic lattice is appreciable only near the boundaries of Brillouin zones, and particularly strong near the corners of these. This leads to the criterion that the metal should be superconductive if a set of corners of a Brillouin zone is lying very near the Fermi surface, considered as a sphere, which limits the region in the momentum space completely filled with electrons.

It will now be shown that this theory affords an explanation of the fact that the superconductive elements lie exclusively in two columns of the periodic table. In the accompanying table they are marked in rectangular blocks, showing that they lie on either side of the so-called 'transition metals'. These metals are characterized by the fact that in going from one to the next along the periodic table, electrons begin to fill the inner zones which previously remained vacant. Thus the bordering columns must have one of the lower Brillouin zones either completely vacant or just filled ; then the necessary condition of superconductivity that the Fermi surface touches the corners of a Brillouin zone will be satisfied.

Periodic table: two columns of superconducting elements, marked in rectangular blocks

From these considerations we can deduce a rule regarding the superconductive alloys and compounds. An alloy formed of two elements from different sides of the superconductive columns will have a better chance of being superconductive than any other alloy. The reason is that the lower Brillouin zone for one element is nearly filled, while for the other element it is rather more than filled, and the combination of them (obtained by forming the alloy) satisfies the requirement of superconductivity. For example, alloys like $BiAu_2$, CuS, which are formed from two elements from either side of the superconductive columns, will be superconductive themselves, though both elements are not.

Thixotropic Behaviour of Petroleum Jelly

If the term 'thixotropy' be restricted to Freundlich's original definition of reversible sol–gel transformation, a peculiar manifestation of this property is strikingly shown by petroleum jelly at varying rates of shear. The phenomenon can be demonstrated with no more elaborate apparatus than a 100-c.c. glass cylinder and a perforated disk as piston, mounted centrally on a metal rod terminating in a ring, a similar arrangement to the familiar 'malted milk mixer'. The plunger not only serves to shear the contents of the cylinder, but also as a rough consistometer, the time of travel of the disk between any two graduations on the freely suspended cylinder serving as a measure, provided the rigidity component of consistency of the material is less than the hydrostatic load of the suspended cylinder.

A petroleum jelly of medium consistency serves for the observation. This should be melted, poured into the cylinder and allowed to set for 24 hours, when the consistency will be generally such that no movement of the disk relative to the jelly takes place when the apparatus is suspended by the ring.

If now the plunger be worked up and down very slowly between its lowest position and, say, the 25 c.c. mark, the shearing resistance will be felt to diminish until suspension from the ring will result in a steady upward travel of the disk through the jelly in the sheared zone. Timing is recorded between any two graduated points within the zone of shear. Measurement is repeated by *slowly* returning the disk to its lowest position once more and again noting the time of travel. Repeated measurements lead eventually to a low constant value of consistency, increasing very slowly indeed on resting the material.

When this sheared jelly is now re-sheared by pushing the plunger up and down as quickly as possible, a rapid and progressive growth of consistency is observed, a few churnings resulting in such an increase of rigidity that the disk remains fixed in position as it did in the original unsheared jelly. The transformation from high to low consistency may be repeated as often as desired.

The optical picture is not very clear. The unsheared material shows thin needle-shaped crystals under polarized light, but rather less in amount than the known heterogeneity would lead one to expect. This may, of course, be due to the bulk of the crystals being of a dimension below optical resolution. The field under paraboloid condenser illumination is quite void, indicating similarity of refractive indices of the component phases. The slowly sheared jelly under polarized light shows a great increase of crystallinity, the crystals, however, apparently having the form of shorter, thicker double cones on a common base. The quickly sheared material again shows needles, but of a shorter length, and, while the field of the original jelly shows some incomplete rosettes, these are here absent.

These experiments followed on qualitative observations on a sample of petroleum jelly which had been variously treated by the alternative methods of melting and quickly chilling to a low and a normal temperature respectively, passing through a three-roller mill, a cone mill, a milk homogenizer and a Werner–Pfleider mixer, the subjective consistencies being in the descending order named.

Precision measurements of mobilities by a capillary plastometer and of rigidities by a parallel plate plastometer are in progress of determination.

Recrystallization of Metals under Stress

In *Nature* of September 11, 1948, Prof. E. N. da C. Andrade and also Messrs. Sully, Cale and Willoughby discuss the recrystallization of metals under stress. This phenomenon has been under observation[1–3] in the Metallurgical Laboratories of the University of Melbourne for some fourteen years; and we have reached the following conclusions relating to lead and its dilute alloys.

(1) Industrial virgin lead, so long as it contains less than 0·001 per cent silver, will, in the annealed state, recrystallize under stress when it has reached 4–5 per cent elongation at strain-rates of the order of 10^{-4}–10^{-5} per day. (2) In the 'as rolled' condition, the recrystallization frequently occurs with less than this amount of deformation. (3) The recrystallization is always accompanied by an increase in grain size, the linear dimensions of the grains increasing by a factor of ten. (4) There is a marked increase in creep-rate during recrystallization. (5) The recrystallization starts at one or more centres and spreads throughout the mass. It can be observed at different stages by intercepting the test and re-etching. (6) The progress of recrystallization can be followed without interrupting the test by observing the slip-line system on the test piece. At first, slip lines change direction at the boundaries of the original small crystals; after recrystallization in any area the slip lines are seen to continue across many of the areas defined as crystals by the original etch. (7) Annealing lead at 120° C. for 24 hours removes the facility for recrystallization at creep-rates of the above order. (8) The phenomenon is noted in alloys of lead with less than 0·05 per cent copper, zinc, bismuth, silver, antimony, respectively. In general, the strain needed is higher: an alloy containing 0·001 per cent silver recrystallized after 10 per cent extension in 300 days caused by a load corresponding to an initial stress of 500 lb./sq. in. (9) Additions of less than 0·05 per cent of calcium, magnesium or tellurium respectively appear to eliminate the recrystallization under the conditions used. (10) In pure lead, vibration facilitates recrystallization. With a creep-rate of 10^{-4}–10^{-5} a day, the phenomenon occurs with about 2·5 per cent elongation when a 50-cycle vibration is superposed on a steady stress.

The creep-rates employed by us have always been much lower than those reported by Prof. Andrade. In our opinion the rate of strain has a fundamental effect on the mechanism of creep.

I do not agree that the transition from constant creep-rate to accelerating creep-rate in uniform load tests is necessarily due either to the increased stress or to recrystallization at this stage, except in the case of single crystals. Hirst[4] has shown that single crystals of lead do fail in this manner.

It is interesting to note from the work in the Fulmer Research Institute that the compression-creep curves reproduce the same features as the tensile-creep curves even though the stress is decreasing under constant load.

Planetary Aberration

THE phenomenon of aberration is usually explained in text-books by considering the motion of the earth past a train of light waves. The special theory of relativity, however, tells us that only relative motions are apparent, and so aberration should occur when a light source is moving relative to an observer. In particular, stars having a component velocity perpendicular to the line of sight should produce an aberration effect. In most stars, this would not be observed, since it would be constant; but binary systems, in which one component has large velocities in its orbit, should show aberration effects. The angle of aberration is dependent only on the relative velocities, not on the distance, and has the direction of the velocity. Thus I would expects numerous observations of stars rotating about one another with large (apparent) angular separation but short period (that of average spectroscopics).

Is there something wrong in the above reasoning, or is it that the effects have been observed and not recognized as aberration effects, but included in the intrinsic orbits ? Other possible reasons for not observing the effect are : (1) the spectroscopic binaries from which we deduce the large orbital velocities are not truly binaries, and some other explanation of them must be found ; or (2) if none of the previous suggestions contains the answer, it would appear that an ether had been found, in which case only the observer's motion produces an effect.

Incidentally, the same reasoning applies to any star rotating on an axis nearly parallel to the line of sight—any measurement of diameter would be dependent on the linear velocity of its equator.

C. O. HINES

576 Sherbourne Street,
Toronto, Ont.

NEITHER classical physics nor relativity supposes that the rays of light from a moving object are curved as a result of its velocity ; the rays which left it at any given time can therefore be prolonged straight backwards (at any later time) until they intersect at the point which it occupied when they were emitted. If a fixed object is also at that point, any observer anywhere will thus see that at the instant of emission the two bodies coincided. Mr. Hines's difficulty has its origin in a misconception ; light leaves the source in *all* directions, not in some specified direction, and although the direction of the particular ray that reaches the observer may depend on the motion of the source, some ray or other will reach him in every case ; and every ray points straight back to the point where the source was at the time of emission. The argument in respect of that particular point is independent of any changes in the velocity of the source, whether before or after, and it thus applies to every point of the orbit of a binary ; if the true orbit were visible as a fixed luminous wire, the star would always be seen on the wire.

Against this background, we may consider the pre-relativity treatment of aberration. In fact, the pre-relativity position already was that to the first order it is only the *relative* motion of the source and observer which matters, for aberration. The subject is treated in some astronomical text-books (for example, Newcomb, "Spherical Astronomy") under 'planetary aberration'. Relativity has extended this statement to all orders; but there is no astronomical case in which higher orders than the first are observable, so that in practice relativity has made no difference. With double stars, however, there is no advantage in considering systems of axes in which first one component and then the other is stationary ; this merely introduces varying displacements of the entire binary system, and is liable to lead to confusion of the sort that has troubled Mr. Hines.

Tissue Suspensions for Estimations of Radioactivity

THE biologist has frequently to devise an appropriate method for the estimation in a liquid counter of radioactive substances contained in tissues. It is desirable that the technique should be both simple and rapid, and the final fluid medium either a solution of the substance or at least a fine, stable, homogeneous suspension of the total tissue which permits dilution and the removal of representative samples. Coarse suspensions tend to produce erratic counting-rates, due, in part, to drifting of the suspended material into zones of reduced tube efficiency; this can often be verified by shaking such a suspension in the counter after particles have been allowed to settle. In the case of such elements as the halogens, preparation from the tissues of a solution containing the radioactive compound becomes a tedious process if loss is to be avoided, and in these cases a suspension appears satisfactory.

Of the common reagents used for this purpose, solutions of potassium hydroxide are unsuitable, since it is possible to obtain, in a counter of 10 c.c. capacity, counting-rates of more than 400 per minute from the presence of the active potassium (K^{40}) isotope alone. Sodium hydroxide, on the other hand, tends to produce from tissue a troublesome gelatinous mass. Working chiefly with brominated organic compounds, I have obtained satisfactory suspensions by boiling the tissue under reflux in a solution of lithium hydroxide containing 20 per cent of alcohol, afterwards washing out the condensers with a little alcohol. Under these conditions, a suspension is rapidly produced which remains reasonably stable for some hours.

Mepacrine Hydrochloride in the Treatment of Avian Coccidiosis

As the result of research in Great Britain and in the United States, the use of certain sulphonamides, particularly sulphamezathine, has become the standard method of treatment of acute cæcal coccidiosis of chickens caused by *E. tenella*. The successful results obtained have tended to focus the attention of workers almost entirely on this group of drugs. The purpose of this communication is to report the successful treatment of the disease by mepacrine hydrochloride.

This drug was used extensively in human medicine during the War, chiefly in the suppression of malaria and also in infestations by certain intestinal protozoa. Until recently, records of its use in animals have been confined to the Continent[1–4]; its effective use in an outbreak of bovine coccidiosis has now been reported in Great Britain[5]. In view of the successful treatment of other animals, Continental workers suggested that it might be evaluated in cæcal coccidiosis of chickens, but to the best of our knowledge no report on this work has been published.

In a preliminary experiment, forty chicks, 10 days old, were dosed with sporulated oocysts of *E. tenella*, and 24 hours later were given 0·1 gm. of mepacrine hydrochloride in 4 pints of drinking-water. The chicks were placed in a brooder and kept on a solid floor, which was not cleaned so that infection might be built up. Drinking-water containing mepacrine hydrochloride in the above-mentioned amount was given daily. Seven deaths occurred as a result of acute cæcal coccidiosis. In a control pen of forty chicks given untreated drinking water, twenty-six died from the disease.

In a later experiment, forty chicks, 21 days old, were each given a single dose of sporulated oocysts and placed in a brooder with a wire floor to prevent massive re-infestation, and given drinking-water containing mepacrine hydrochloride (0·1 gm. to 4 pints of water). Seven deaths occurred compared with twenty-three deaths in the control pen.

The drug was well tolerated; one group of chicks, 10 days old, received mepacrine hydrochloride solution in the above concentration in place of drinking-water continuously for six weeks. They drank the medicated water readily, ate well throughout the period of observation and showed no symptoms beyond a slight ruffling of the feathers. Their average weight, however, was 3 oz. less than that of a similar group of chicks given mepacrine hydrochloride continuously for three weeks, followed by ordinary drinking-water during the remainder of the experiment. The average weight of the latter group was that of normal chickens of the same age. Three weeks later, however, the weights of both groups were equal. It would appear, therefore, that even prolonged dosing has no lasting adverse effects.

Mepacrine hydrochloride is readily soluble in water, and in the very weak solution used in these experiments it is both effective and cheap. It is probable that even better results would follow a higher concentration in the drinking-water. One gram to each gallon of water is tentatively suggested; treatment to commence as soon as blood is noted in the droppings and to continue for five to seven days.

Experiments along these and other lines are proceeding, and it seems that mepacrine hydrochloride may become a most useful agent in combating avian coccidiosis, a serious disease of chickens, particularly in the event of the development of strains of coccidi resistant to sulphonamides.

Mepacrine hydrochloride in the form of free-flowin granules prepared by May and Baker, Ltd., unde the trade name of 'Mecryl', was used in the experiments described, and the advice of this firm ha been greatly appreciated.

Chromatography of Nucleic Acid Derivatives

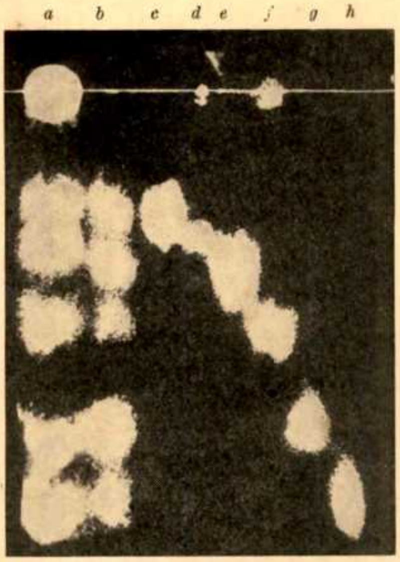
THE nucleic acids and their derivatives ar fundamental constituents of biological systems; bu until recently workers have lacked precise micr methods for their study. Vischer and Chargaff[1], an recently Hotchkiss[2] and also Reichard[3], have show that partition chromatography[4] may be used t separate and characterize certain derivatives. Th methods employed by these workers to detect th spots on the chromatograms were, however, eithe limited in their scope or necessitated the analysis o a large number of fractions selected arbitrarily fro the columns.

We have approached this problem in a differen way. Purine and pyrimidine derivatives are characterized by an intense ultra-violet light absorptio in the region of 2650 A., and they can be detecte in amounts of 10 μgm. or less by a simple photographic technique.

The source of ultra-violet light used in these experiments is a quartz mercury vapour lamp (Hanovi Homesun, 200 V. D.C., 450-watt) fitted with a ventilated shield having an aperture cut opposite th middle of the tube. The light from this is filtere through two quartz filters having a free aperture o 22 mm., one 35 mm. thick, containing dry chlorine and the other 30 mm. thick, containing a salt solutio ($NiSO_4.7H_2O$, 350 gm., $CoSO_4.7H_2O$, 100 gm. pe litre[5]). The light passed by these filters in the ultra violet, mainly the 2537 A. and 2650 A. mercury lines is absorbed by purine and pyrimidine derivatives while the visible light transmitted has no effect o the photographic material used.

Chromatograms run in *n*-butanol in an atmospher containing ammonia on Whatman No. 1 paper ar dried and pinned on to a slightly convex cylindrica surface over a strip of Ilford Reflex Document Pape No. 50. This is then exposed at a distance of 120 cm to the ultra-violet light for 1½ min. and develope in a process developer (Kodak *D*153), fixed, washe and dried. The absorbing substances show up o the black background as light areas (see reproduction) and the corresponding areas of the filter-paper ma be cut out, extracted in water and estimate spectrophotometrically.

While the positions of the various purines, pyrimidines and nucleosides on our chromatograms agre reasonably well with those observed by Hotchkiss



Chromatogram run for 20 hr. in *n*-butanol – water of (*a*) turnip yellow mosaic virus nucleic acid hydrolysed with formic – hydrochloric acid for 4 hr. at 115°. The top spot is due to nucleotides and unhydrolysed nucleic acid ; (*b*) an artificial mixture of the nucleosides and bases known to be in the hydrolysate ; (*c*)–(*h*) the components of the mixture run individually : cytidine, guanine, uridine, cytosine, uracil and adenine

we find that the relative rates of movement of these substances depend greatly on the concentration of ammonia in the vapour phase. For example, the relative positions of uridine and cytidine can be reversed by changing the ammonia vapour pressure. We also find that guanine, if in sufficiently low concentration to dissolve completely in the aqueous phase of the chromatogram, moves at a rate exceeding that of guanosine, and we imagine that it corresponds with the "epiguanine" mentioned by Hotchkiss. We think that the latter used too large an amount of guanine, and as most was undissolved it remained at the zero spot. Hydrolysis of yeast and virus nucleic acids by ammonia according to the method of Levene[6] results in the liberation of part only of the material as nucleosides, and these may be degraded still further. For example, adenosine treated in this way is found to contain four substances : adenosine, adenine and two others, probably inosine and hypoxanthine. The hydrolysis of ribonucleic acid by pyridin–water (Bredereck *et al.*[7]) is far from complete, and the hydrolysate contains at least seven different substances. In fact, we have failed so far to find a method for the quantitative hydrolysis to nucleosides. For hydrolysis of nucleic acid to the bases, the formic–hydrochloric acid mixture of Graff and Maculla[8] has been found most satisfactory for the liberation of adenine, and with prolonged hydrolysis a large part of the pyrimidine bases is liberated. The accompanying reproduction is from a photograph of a chromatogram of turnip yellow mosaic virus nucleic acid hydrolysed in this manner, showing the four bases which are also found in yeast nucleic acid.

It is possible to apply this method to the investigation of the kinetics of reactions such as the hydrolysis of nucleic acids, spots corresponding with the various products appearing and disappearing with time. Other absorbing substances, notably tryptophan, may, of course, be detected by this technique.

A fuller account of this work will appear elsewhere.

We should like to record our appreciation to Dr. Kenneth M. Smith, for his interest and encouragement, and to Dr. J. Davoll and Dr. T. Mann, for the gift of several nucleosides.

Genic Differences and Rate of Growth in Yeasts

A BREWERY diploid strain of yeast kept under constant observation for the past two years showed a seasonal variation in the characteristics of its giant colonies. On the basis of normal[1] and induced reverse mutations[2], it was surmised that different mutants get established during the various seasons of the year, and hence strains having diverse genic constitutions should differ not only in their viability but also in their growth-rate under particular environmental conditions. It was shown in a previous contribution[3] that the growth-curves of the diploid and autotetraploid are widely different. Since strains having different genic constitutions were available in this Laboratory, it was considered that a study of the growth-rates of two strains assumed to be homo- and heterozygous for the *rough* allele would be interesting.

The strain *BY* 4 was isolated from an active wort culture of the control (*BY* 1) kept in a cold room for ninety days[4]. In February 1947 its giant colony had radiate folds as illustrated in Fig. 1 (1). This strain also showed a cyclical change in its characteristics, and in September 1947 the entire surface of its

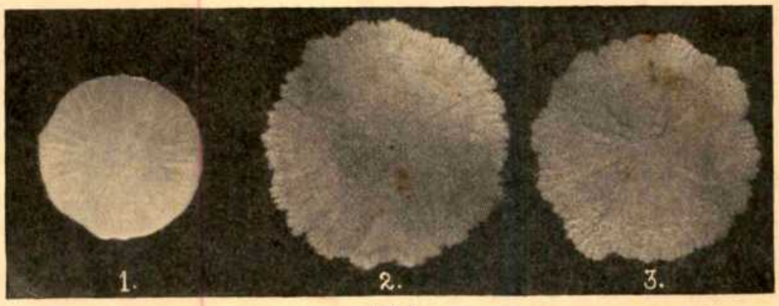

Fig. 1

BY 4. 2·8 cm. 14 days growth (Sept. 30, 1947).

BY 1. 3·1 cm. 16 days growth (Nov. 3, 1947)

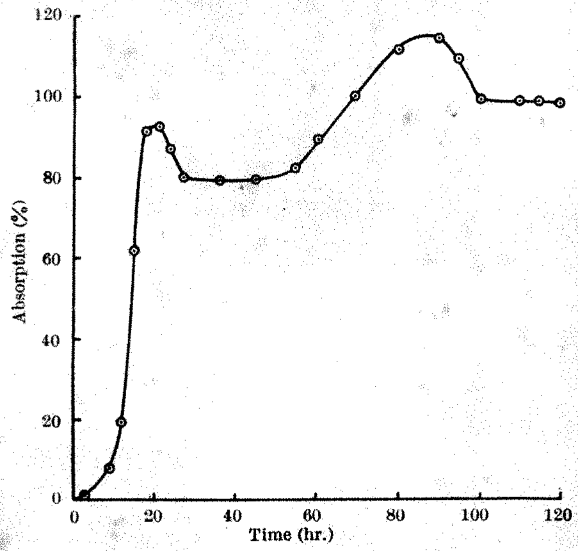

Fig. 2. Growth curve of *BY* 1

colony had a rough sculpturing (Fig. 1 (2)). During the same period the rough sculpturing was limited to the outer half of the colony in the control culture (Fig. 1 (3)). From the later orderly stages of reversion to the smooth type of colony observed in both the strains, it was assumed[4] that while the strain *BY* 4 was homozygous, the control was heterozygous for the *rough* allele.

The investigations on the growth-rates were carried out in the months of August and September 1947. The growth of yeast inoculated into 5 ml. of a standard all-vitamin synthetic medium[6] in 100-ml. conical flasks and incubated at 28° C. was measured at definite intervals using a Lumetron turbidometer. The turbidity obtained at the end of 120 hours was adjusted in each case to read 100 in the turbidometer, and the other readings were taken in terms of this standard.

While the general nature of the two growth-curves are similar (Figs. 2 and 3), the differences between the two strains are shown in the accompanying table.

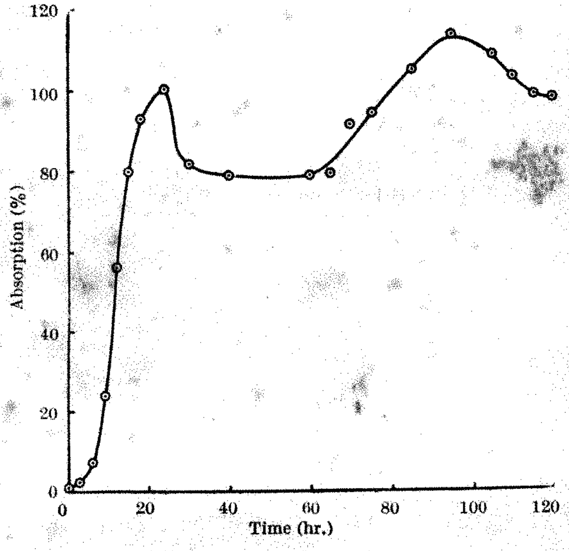

Fig. 3. Growth curve of *BY* 4

	BY 1	*BY* 4
1. End of lag phase reached in	9 hr.	6 hr.
2. End of logarithmic phase reached in	21 hr.	24 hr.
3. Fall in curve	Until 33 hr.	Until 33 hr.
4. Secondary rise commenced at	50 hr.	65 hr.
5. Secondary maximum reached at	85 hr.	95 hr.

Dodge, Dodge and Johnson[7] observe "that there is a definite cycle of fluctuations in the physiology of the cultures". They further state : "Reappearance of very high dry weights (over 90 mgm. under our standard conditions) in approximately six-month periods suggests this as an approximation for the cycle of our stock culture" (pp. 24–25). It would be seen, however, that their explanation that "each culture behaves as liquid tissue of an individual with physiological as well as morphological differentiation of cells" is questionable in view of the explanations now offered.

A perusal of the curves would indicate that the rate of growth of *BY* 4 is slower. Hence it is likely to get gradually eliminated, if by mutation a type heterozygous for the *rough* allele originates in the active culture. Such differential viability and growth-rates of the mutants may explain the establishment of particular types (cf. Braun[8]) when grown at laboratory temperature during the different seasons of the year. It naturally follows that growth of various types of mutants ought to be different during the changing seasons of the year. Wide variations may occur between the relative growth-rates of two strains in two different seasons.

Any investigation of growth-rates of different strains would, therefore, become intelligible only if their genic constitution and variations in the same are known.

Growth and Development of 'Mung' (*Phaseolus radiatus* Linn.)

The effect of different times of sowing throughout the year on the growth and development of two varieties of 'mung' (*Phaseolus radiatus* Linn.)—Sona mung and I.P.28—sown in pots has been described fully in a recent paper[1]. In this note the effect of different times of sowing on the growth and development of mung sown in replicated small plots in the field will be discussed very briefly; details will be published later.

The final observations and measurements at the fruiting stage of the plants are given in the accompanying table, each figure representing the mean of twelve plants selected at random from each of the plots.

	Sona mung				I.P. 28			
Dates of sowing	Height (cm.) (*a*)	No. of nodes (*b*)	*a*/*b* (*c*)	Days for budding (*d*)*	(*a*)	(*b*)	(*c*)	(*d*)*
Aug. 15	47·6	16·6	2·9	64·6	19·2	6·6	2·9	35·0
Sept. 14	25·2	11·3	2·2	46·0	16·5	6·3	2·6	43·3
Sept. 29	13·5	5·6	2·4	35·8	11·6	5·0	2·3	39·1
Oct. 14	14·0	5·0	2·8	29·5	14·0	5·6	2·5	38·3
Oct. 29	10·4	4·5	2·3	28·6	10·3	4·6	2·2	49·6

* Days for budding = mean days required for flower-bud formation as calculated from the date of sowing up to the date when first flower-bud was just visible.

The results show that there is a correlation between the heights and the corresponding numbers of nodes in the case of both varieties, but that between the heights and the corresponding 'days for budding' is found only in the case of Sona mung. There is also a decrease in height in the case of both varieties for September 29 sowing ; but the corresponding decrease in the number of nodes is only observed in the case of I.P.28. Although there is no correlation between the times of sowing and the ratio of the height to the number of nodes, it is of interest to note that the ratio always lies between 2·2 and 2·9, and that it is highest for the August 15 sowing in the case of both varieties. Again, when sowing was delayed until October, both the varieties became almost similar in height and in the number of nodes, and this was only possible due to the rate of decrease in height and in the number of nodes being much more pronounced in Sona mung than in I.P.28.

In situ Development of Carpospores of *Bonnemaisonia asparagoides*

In their researches on *Bonnemaisonia asparagoides* (Woodw.) C. Ag., J. Feldmann and G. Feldmann[1] describe the germination of the carpospores. After showing amœboid movement, the spores become round and surrounded by a wall. The first division is equatorial and at right angles to the substratum. Other walls parallel to the first are formed, and subsequent divisions lead to the formation of a hemispherical cushion of cells from the edge of which radiating filaments ultimately develop. This account agrees with the earlier published descriptions given by Kylin[2,3] and Chemin[4], and also Golenkin[5], who recorded some variation in the position of the first wall.

During an examination of *B. asparagoides* (collected from the Tan Buoy, Millport, Cumbrae, in 1928) germinating spores were observed in three cystocarps. Some of the sporelings were free in the hollow of the cystocarp while others were still attached to the placenta (Fig. 1). The method of germination of these spores is clearly somewhat at variance with the accounts given by the authors cited above (Fig. 2). In the first place, each carpospore has germinated within the sporangium, many of the sporelings being pear-shaped and thus having the same shape as mature spores. They cannot, therefore, have shown any amœboid movement. The most notable features of the sporelings, however, are the conspicuous apical cell (Fig. 2) and the method of germination, which resembles the bipolar type found in the Ceramiales.

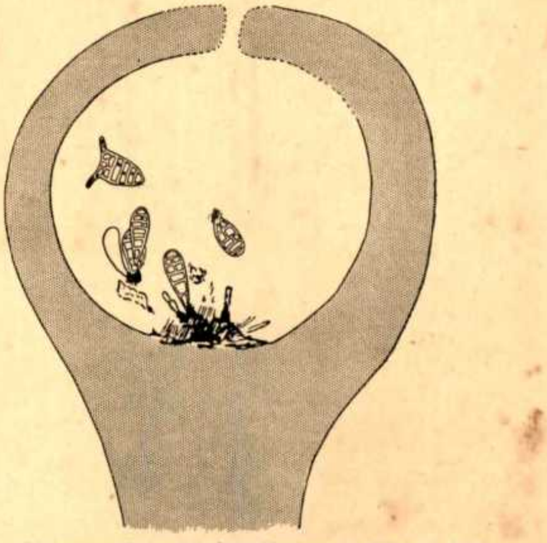

Fig. 1. Diagrammatic tracing from photograph of spores germinating in cystocarp of *Bonnemaisonia asparagoides*. (× 50)

Our knowledge of the life-history in this and related species, as well as of neighbouring genera, is very inadequate and incomplete, particularly with regard to the phase between the liberation of the carpospores and the re-appearance of the gametophyte. Further investigations, the need for which is indicated by these new observations on germinating carpospores, might have as their main objects : (*a*) the elimination of the apparent contradictions in existing accounts of the life-history of *B. asparagoides*, for example, whether under some conditions the gametophyte arises from a special branch of the filamentous growth[3] as well as from the tetraspores[1], and if under other conditions it may arise directly from the carpospore, as is perhaps suggested by the figures published here ; (*b*) to ascertain whether the tetrasporangia, which are said[1,6] to develop on the filamentous growth originating from the carpospores, are homologous with the tetrasporangia of the Ceramiales or simply accessory reproductive spores possibly on occasions reproducing the filamentous growth ; and (*c*) the effect of seasonal factors on morphological development.

In view of the rather ephemeral nature of *B. asparagoides* and its deep-water habitat, it may well be that further investigations of *Batrachospermum* under controlled conditions of culture may be the

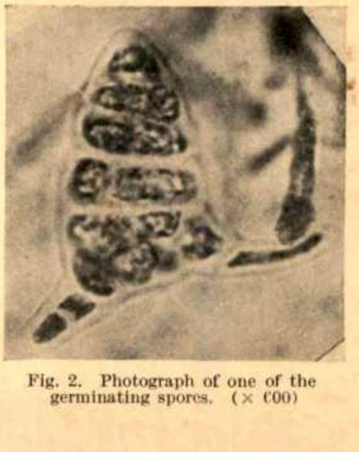

Fig. 2. Photograph of one of the germinating spores. (× 600)

means of elucidating obscure points in the development of those Nemalionales which possess simple filamentous stages.

The Feldmanns[1] have suggested that the microscopic stage of *B. asparagoides* is a tetrasporophyte, and that the life-history might be regarded as occupying an intermediate position between the *Nemalion* and *Polysiphonia* types. While this seems unlikely, both on general grounds and because of the great dissimilarity of the two phases, it is possible that *Bonnemaisonia* may represent an elaboration of the *Nemalion* type along another line of development. The importance of this question indicates how desirable are further investigations.

Posterior Lobe of the Pituitary Gland and the Metabolism of Lipides

THE acetone extract from posterior pituitary lobes of cattle includes a number of substances of special interest. One of these substances decreases the growth-rate of young animals, plant seedlings and transplantable mouse carcinoma[1-3]. Another substance when injected into white mice of practically cancer-free strain causes the appearance of malignant tumours in about 25 per cent of the animals treated[4].

Further investigations have shown that the extract includes a substance which, when injected into rabbit or dog, lowers the amount of cholesterol present in the blood serum[5]. The decrease affected free, as well as esterified, cholesterol.

An acetone extract of posterior pituitary lobes of cattle when successively treated with ethyl ether, ethanol, petroleum ether and methanol yields also another fraction which, after subcutaneous injection into the dog, increases the amount of cholesterol present in the blood serum of the treated animal. Two other fractions were also obtained from the acetone extract, one of which decreases the serum phospholipide content, and the second of which increases the serum lipide content in the dog.

Of the more than a hundred experiments performed we quote some typical protocols. Healthy dogs of about 8 kgm. weight were used in the experiments. Cholesterol was measured by the method of Schoenheimer and Sperry[6], phospholipides by the method of Youngburg and Youngburg[7]. The serum lipide values in mgm. per cent are given prior to, and three hours after, subcutaneous injection of the particular fractions.

I. Dog *AC*, injected with 12 mgm. of fraction *A*

Cholesterol :			
total :	before, 132·0 ;	after, 106·0 ;	decrease, 19·8 per cent
free :	,, 40·0 ;	,, 36·0 ;	,, 10·0 ,,
esters :	,, 92·0 ;	,, 70·0 ;	,, 23·9 ,,
Phospholipides :	,, 17·0 ;	,, 14·8 ;	,, 12·9 ,,

II. Dog *BX*, injected with 1·4 mgm. of fraction *B*

Cholesterol :			
total :	before, 170·0 ;	after, 214·0 ;	increase 25·8 per cent
free :	,, 44·0 ;	,, 64·0 ;	,, 45·5 ,,
esters :	,, 126·0 ;	,, 150·0 ;	,, 19·1 ,,
Phospholipides :	,, 28·5 ;	,, 28·5 ;	no change

III. Dog *M*, injected with 15 mgm. of fraction *C*

Cholesterol :			
total :	before, 150·0 ;	after, 160·0 ;	increase, 6·7 per cent
Phospholipides :	,, 23·68 ;	,, 19·68 ;	decrease 16·9 ,,

IV. Dog *S*, injected with 10 mgm. of fraction *D*

Cholesterol :			
total :	before, 186·0 ;	after, 182·0 ;	decrease, 2·2 per cent
Phospholipides :	,, 13·2 ;	,, 16·7 ;	increase, 26·6 ,,

The chromatographic separation of the cholesterol-depressing fraction *A* yielded even more interesting results. The cholesterol-depressing effect is due to three different substances, one of which lowers only the ester-cholesterol content of the serum, while the second substance lowers free cholesterol, and the third substance lowers esterified and free cholesterol both at the same rate. The action of these substances is especially manifest 24 hours after the subcutaneous injection.

We enclose typical experimental protocols giving the serum lipide values in mgm. per cent prior to, and 24 hours after, the injection of the particular fractions :

V. Dog *BH*, injected with 1·0 mgm. of fraction 33*E*

Cholesterol :			
total :	before, 108·0 ;	after, 72·0 ;	decrease, 33·3 per cent
free :	,, 28·5 ;	,, 28·5 ;	no change
esters :	,, 79·5 ;	,, 43·5 ;	decrease, 75·4 ,,
Phospholipides :	,, 20·68 ;	,, 20·32 ;	,, 1·7 ,,

VI. Dog *BN*, injected with 12 mgm. of fraction 3*EN*2

Cholesterol :			
total :	before, 130·0 ;	after, 114·5 ;	decrease, 11·9 per cent
free :	,, 46·0 ;	,, 31·6 ;	,, 31·4 ,,
esters :	,, 84·0 ;	,, 82·9 ;	,, 1·3 ,,
Phospholipides :	,, 24·5 ;	,, 24·5 ;	no change

VII. Dog *BQ*, injected with 10 mgm. of fraction 3*BE*

Cholesterol :			
total :	before, 167·0 ;	after, 100·0 ;	decrease, 40·0 per cent
free :	,, 52·0 ;	,, 30·0 ;	,, 42·3 ,,
esters :	,, 115·0 ;	,, 70·0 ;	,, 39·2 ,,
Phospholipides :	,, 24·1 ;	,, 23·5 ;	,, 2·5 ,,

Investigations are in progress aiming at the isolation of the active substances in a pure state.

'Lewis' Blood-Group System

WHILE our first communication describing the Ken antigen was in the press[1], R. R. Race informed us of the discovery by Andresen of irregular agglutinins anti-L_1 and anti-L_2 [2,3], the latter giving reactions very similar to our anti-Ken serum. Andresen recognized that the L_1 character was, in fact, the 'Lewis' blood-group described by Mourant[4].

On the other hand, the anti-L_2, as our anti-Ken, gave a higher proportion of positive reactions with *O* bloods. But Andresen pointed out that the defect in positive reactions was found in the A_1 group only, while the A_2 group behaved as the *O* group. He explains the difference by an epistatic action of the property A_1 (or the gene p_1) on the development of the property L_2.

This explanation does not seem probable, in the light of the action of blood-group substances on both anti-Ken and anti-L_2 sera[5]; essentially, the addition of Witebsky's substances to anti-Ken serum and of Morgan's purified A-group substance to anti-L_2 removes the difference in the distribution of positive and negative reactions observed among O- and A-cell groups when unabsorbed serum is used.

It seems, then, more reasonable to postulate a serological explanation of the difference observed when unabsorbed serum is used: anti-Ken and anti-L_2 would contain two antibodies, one of which accounts for the agglutination of 50 per cent of bloods in all A- and O-groups, and the other capable of uniting with the A_1 receptor (as it possesses a definite affinity for the A blood-group substance) without giving any agglutination but being diverted from its specific receptor responsible for the agglutination of 'the surplus' in O- and A_2-groups.

Suitable absorption experiments should solve this problem and verify the value of our hypothesis.

We have studied a few families, and we have found that whenever Ken was absent in both parents, it could not be found in the children. On the contrary, some Ken + parents had in certain cases Ken − and Ken + children. It would appear, therefore, that Ken is dominant over its absence. This point can only be established when the exact number of agglutinins in anti-Ken serum is known.

Finally, we wish to lay stress on the possibility of immunization against the antigens of the 'Lewis' group system.

If Mourant's anti-Lewis and Andresen's anti-L_1 and L_2 sera behave like 'natural' irregular iso-agglutinins, anti-Ken was definitely of immune origin and gave rise to hæmolytic disease of the newborn.

Colour Discrimination in the Dronefly, *Eristalis tenax*

DIFFERENTIAL reactions to various wave-lengths or wave-length bands, independent of intensity, have been claimed for several members of the group of Diptera[1-4]. None of the authors concerned, however, had based his experiments on the training method which, when applied to honey-bees, had yielded more detailed and exhaustive results than any other method[5,6]. It may therefore be of interest that a solitary insect belonging to the group of Diptera has been trained to colours successfully for the first time, in preliminary experiments carried out in this Department.

A number of droneflies, mostly *Eristalis tenax*, caught feeding on yellow flowers, were trained to find their food (sugar-water) on flower models made of coloured papers, offered in a greenhouse. The papers belonged to the Ostwald standard series which consists of twenty-four different hues; each hue, denoted by a figure (1 to 24), is available in different shades of lightness and saturation, indicated by letters following the numbers. *Eristalis* quickly learned to find their food on models cut out of the training colour Ostwald yellow 2 *na*, the letters *na* indicating the most saturated shade.

In order to find out whether the insects recognized the specific wave-length band reflected by the yellow paper, or its special degree of lightness, which need not be the same for the insect's eye as for our own, the following arrangement was offered, without any food, in the first series of test experiments: models not only in the training colour, but also in two other shades of the same yellow hue, were presented, together with models in various steps of grey, ranging from black to white, of the Ostwald grey series. We have to make the assumption that these grey papers appear neutral or near neutral also to the insect's eye, at least when illuminated by full sunlight, which was guaranteed by a large 'Perspex' window let into the south wall of the greenhouse. If the flies had selected the training colour for its particular degree of lightness, they would either have confused it with one of the grey steps, or they would have selected only one of the yellow shades.

The accompanying table, from which the wide variation in lightness value for man (reflectance) among the yellow shades is apparent, shows the results in raw figures; the proportion of coloured models to neutral ones was one in five.

Test experiment 1, 1–3. Ostwald yellow No. 2, in three shades of lightness, among various steps of Ostwald grey

	Shade	Reflectance	Visits on colour	Visits on all grey steps
(1)	Yellow 2 *ia*	0·55	29	3
(2)	Yellow 2 *na*	0·50	49	1
(3)	Yellow 2 *ne*	0·21	27	7

The selection of each of the three different shades of the same yellow hue from among all grey steps excludes the possibility that the insects were trained to one degree of lightness; they must have recognized the training colour, as well as the two other shades of yellow No. 2, by the specific wave-length region reflected. (Any influence of a smell that might be inherent in the yellow papers had been ruled out in control experiments where the whole arrangement had been covered with a 'Perspex' plate.) Accordingly, the results of the first set of tests prove the existence of colour discrimination in the dronefly.

In another set, consisting of two test experiments, models in the training colour were offered side by side with models in other colours also belonging to the saturated Ostwald *na* papers; the total number of visits was 120. The training colour No. 2 was definitely preferred to red, green, blue and violet, that is, coloured papers reflecting wave-length bands fairly different from its own; it was preferred, to a *lesser* extent, to those colours nearer to it in the Ostwald series, namely, No. 24 and No. 1 (greenish-yellow) and No. 3 and No. 4 (orange), which reflect wave-length bands similar, or adjacent, to those reflected by yellow 2, whereas their lightness values vary over a wide range.

In a third set of tests, four shades of lightness of yellow No. 2 (2 *na*, *ne*, *ia* and *ie*) were offered, together with four different shades of lightness of blue 14 (*na*, *ne*, *ia*, *ea*). The yellow shades received a total of 47 visits as compared with a total of only 3 visits on the blue shades. These results make it probable that, in the same way as the discrimination between yellow and grey, the discrimination between yellow and various other colours, particularly between yellow and blue, is also due to differences in wave-length bands reflected, independent of differences in degree of lightness.

A spontaneous feeding response to various colours, with a high peak in yellow, has been shown to exist in the butterfly *Vanessa polychloros*[7]. Without using insects bred from pupæ, it cannot be decided whether the results mentioned thus far could not perhaps have been caused by a similar inborn response to yellow in *Eristalis*. However, this explanation does not hold good for the results obtained after an attempt to train the insects to blue, which unfortunately could not be completed owing to the end of the season. In a last series of tests carried out with *Eristalis* fed on blue 14 *na* for several days, blue shades which had been practically neglected in previous tests received at least as many visits as yellow shades (total number of visits on coloured models, 69). This proves that a certain amount of training must have been involved. Thus there is every reason to hope that *Eristalis* may prove a very suitable object for a systematic study of its colour discrimination which it is intended to carry out in this Department during next spring.

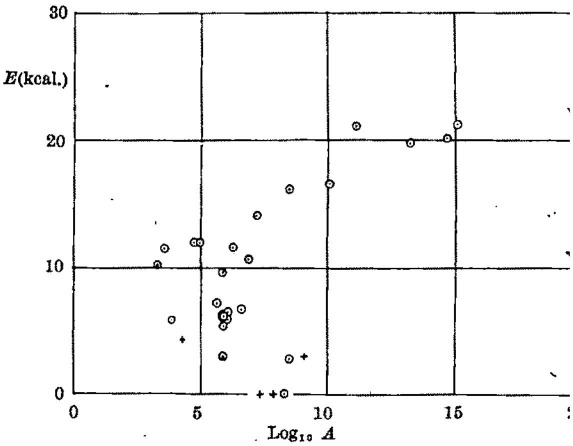
Frequency Factors in Radical Reactions

THE frequency factors and activation energies for reactions in the polymerization of styrene and vinyl acetate have been determined in these Laboratories[1]. By combining the values for chain propagation with the results of Lewis, Mayo, Walling and their collaborators[2], activation energies and frequency factors can be calculated for a number of transfer and propagation reactions of the styryl radical. The accompanying diagram is a plot of E against $\log_{10} A$ for the twenty-nine reactions. It will be seen that the frequency factors are in general low, the mean value of $\log_{10} A$ being 7·4, instead of the normal value *c*. 12. As Gregg and Mayo[2] point out, there is, however, a tendency for reactions with high activation energies to have higher frequency factors.

Attention has often been directed to the fact that frequency factors in polymerization reactions are usually low, but this has been ascribed to steric effects in the reactions of large molecules. However, any size effect should be most marked in the termination reaction in a polymerization, whereas, in the cases quoted, the latter has the highest frequency factor.

The values reported above for the autoxidation of tetralin are also plotted (crosses in the diagram). The mean value of $\log_{10} A$ for the four reactions is



7·1, in good agreement with the mean for the pol merizations. Here no size effect would be anticipate

It seems reasonable to infer that organic radic reactions with activation energies less than abo 20 kcal. in general have frequency factors of the ord of 10^7, and not 10^{12} as is commonly assumed. Steaci has tentatively suggested that this is also true in g reactions.

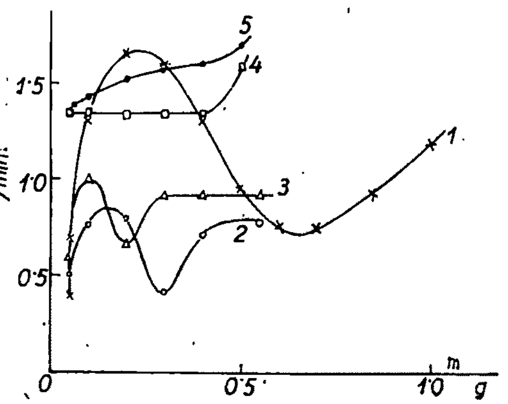
Rate of Hydrogenation in Solutions and the Mass of the Catalyst

IN order to clear up the remarkable relation betwe the rate of hydrogenation and the mass of t catalyst, found by Kailan and Hartel[1], as well as Csürös and co-workers[2], we made a systematic i vestigation on the hydrogenation of crotonic acid a sodium cinnamate in aqueous solutions in conta with hydrogen gas in the presence of palladium pr cipitated on finely dispersed barium sulphate. was found that the product of the hydrogenati (namely, butyric acid in the experiments wi crotonic acid) accelerates the reaction autocatalyti ally.

The initial rate of hydrogenation (v) as a functi of the mass of catalyst (m) has, in pure aqueo solutions, in agreement with the authors above me tioned, a maximum and a minimum (see graph). W found that the value of v and the shape of the cur $v = f(m)$ is greatly influenced by the velocity stirring, the ratio r of the surface to the volume the solution, and the nature of the electrolyt present in the solution. If the velocity of stirring moderate (magnetic stirrer moving in a circle 3 times per minute) and r being small (1–3·4 cm.^{2}/cm.^{3} the curve $v = f(m)$ has a maximum and minimu



Rate of hydrogenation of a 0·13 mol. sodium cinnamate solution (in n cm.^{3} consumed hydrogen per minute). Curve 1, sodium cinnamate alone ($r = 2{\cdot}4$); curve 2, with an addition of 0·033 mol. ammonium chloride ($r = 3{\cdot}4$); curve 3, the same ($r = 2{\cdot}7$); curve 4, the same ($r = 1{\cdot}6$); curve 5, the same ($r = 1{\cdot}0$)

If, on the other hand, the solution is vigorously shaken, the rate of the hydrogenation increases proportionally with the mass of the catalyst.

The shape of the curve $v = f(m)$ is different in the presence of ammonium salts in the solution, showing, in appropriate circumstances, neither maximum nor minimum, even if the stirring is not rapid. The shape of the curve is greatly influenced by r. Varying r, v can be made independent of m; moreover, the maximum can also re-appear (see graph). The ions Na^+, H^+ and Cl^- have no such influence. It should be mentioned that the electrokinetic potential of the catalyst is essentially influenced by ammonium ions, suggesting that the alteration of the $v = f(m)$ curve is—partly at least—caused by this factor. The experimental results suggest the following explanation.

The fraction of the catalyst on the surface of the solution and near it has a greater catalytic action than the fraction in the solution. This behaviour can be correlated with various factors, one of which is the fact that the catalyst near the surface of the solution, which is in almost direct contact with the hydrogen gas, contains more adsorbed hydrogen than that in the solution, the rate of the hydrogenation being, *ceteris paribus*, undoubtedly proportional to the concentration of hydrogen per unit area of the surface of catalyst. Within the solution, the concentration of hydrogen is under stationary conditions lower than in equilibrium, having regard to the point that the reaction is consuming a certain amount of hydrogen, the support of which by diffusion and convection is rather slow.

The increase of mass of the catalyst has various effects on the rate of the reaction. On one hand, the quantity of the catalyst near the surface of the solution will be increased, accelerating the reaction, although the velocity of stirring, the pressure of hydrogen and surface area of solution are kept constant. The increased rate of hydrogenation near the surface diminishes, on the other hand, the diffusion of the hydrogen in the solution, since a greater part of the hydrogen dissolved per second from the gas will be consumed near the surface than in such experiments in which we are applying a smaller amount of catalyst, and only a smaller part of the hydrogen can be transferred into the solution. The concentration of the hydrogen is consequently diminished in the solution, and the adsorbed quantity per unit area of the catalyst diminishes also, all the more so as the whole area of the catalyst is increased.

The effect in the solution is twofold: on one hand, the increase of the whole area of the catalyst is accelerating the reaction; on the other, the decrease of the adsorbed amount of hydrogen per unit area of the catalyst is retarding it. It depends on the experimental conditions which of these two effects is to prevail. The rate of the reaction in the solution can therefore be diminished or increased by increasing the quantity of the catalyst. A more detailed development of this consideration shows that the shape of the theoretical curve $v = f(m)$ is, under adequate conditions, similar to that of the experimental curves. Further investigations on the quantitative agreement are in progress.

Fuller details of the above-mentioned experiments and considerations, carried out in collaboration with J. Szabó, will be published elsewhere.

Sun-bathing by Birds and its Anti-rachitic Value

In the issue of *Nature* of November 27, p. 843, there is a note on the subject of sun-bathing by birds, quoting *British Birds* as saying that the question has been raised "whether irradiation of the skin with its consequent effect of vitamin D production would take place through sun-bathing".

In this connexion I should like to direct attention to the publications by Hou[1,2] in 1930 on this subject. Hou found by feeding tests that the skin and feathers of fowls exposed to the sun in the usual way were anti-rachitic, but that if the birds' preen glands were removed, and vitamin D excluded from their diet, they developed rickets.

From these results we can reasonably assume that one of the functions of preening is to enable the bird to secure and swallow irradiated preen gland oil, which suggests that direct irradiation of the skin is not necessary for birds to keep them free from rickets.

It seems highly probable that, in the case of mammals which have a thick enough coat of hair or fur to prevent direct access of sunlight to the skin, the sebaceous secretion which lubricates the hair contains antecedents which are converted into vitamin D by irradiation. The elaborate toilet of the fur by such animals would therefore be comparable physiologically with preening by birds. According to Hou and Tso[3], human sebum is anti-rachitic, and Hou found that if rabbits' ears were washed with ether, irradiation of the ears by a mercury vapour lamp could not cure rickets induced in the animal, but that it could if the fatty substances were not removed.

DERIVATIVES OF *CENTELLA ASIATICA* USED AGAINST LEPROSY

Chemical Constitution of Asiaticoside

CENTELLA asiatica (Urban) (*Hydrocotyle asiatica* L.) is a plant of the family Umbelliferæ. Infusions of this plant are utilized in India and Madagascar against leprosy; it is also mentioned in the French Pharmacopœia of 1884.

Bontems[1] reported in 1942 the isolation from *Centella asiatica* of a crystalline glycoside which he called asiaticoside. Devanne and Razafimahéry[2] proposed the formula $C_{21}H_{34}O_8$ for this glycoside, and stated that hydrolysis gives one molecule of glucose and an amorphous aglucone $C_{15}H_{24}O_3$.

We have recently begun a study of the chemical constitution of asiaticoside, using crystalline material produced on a pilot-plant scale in Tananarive (Madagascar)[3]. After three recrystallizations from dilute alcohol we obtained colourless prisms, m.p. 230–233° (decomp.), $[\alpha]_D = -14°$ (in alcohol). Elementary analysis and the composition of the products of hydrolysis are in agreement with the formula $C_{54}H_{90}O_{23}$, or $C_{54}H_{88}O_{23}$ for asiaticoside (found: C, 58·18, 58·38; H, 8·32, 8·25; calculated for $C_{54}H_{90}O_{23}$: C, 58·54; H, 8·21 per cent).

Acid or alkaline hydrolysis of asiaticoside proceeds remarkably rapidly and gives an aglycone and two different sugars. These have been identified as glucose and rhamnose, by preparation of crystalline derivatives, and by partition chromatography on paper[4]. A quantitative determination of rhamnose by the method of Nicolet and Shinn[5] indicates the presence of two molecules of rhamnose for one molecule of asiaticoside (found, 28·98 per cent rhamnose; calculated, 29·63 per cent). The optical rotation of the sugar mixture formed by hydrolysis and the reducing power as determined by the method of Bertrand[6] show that asiaticoside contains two molecules of D-glucose and two molecules of L-rhamnose.

The aglycone of asiaticoside is a triterpene acid, $C_{30}H_{48}O_5$ or $C_{30}H_{50}O_5$, which we propose to call 'asiatic acid'. The hydrolysis of asiaticoside thus proceeds as shown by the following equation:

$$C_{54}H_{90}O_{23} + 4\,H_2O = C_{30}H_{50}O_5 + \underset{\text{glucose}}{2\,C_6H_{12}O_6} + \underset{\text{rhamnose.}}{2\,C_6H_{12}O_5}$$

Free asiatic acid is very difficult to crystallize (m.p. 240–244°, after purification through its sodium salt, m.p. 310°), but its methyl ester, obtained by methylation with diazomethane or dimethyl sulphate, crystallizes readily (needles, m.p. 225° (corr.), $[\alpha]_D = +52°$ (in alcohol) and analyses correctly for $C_{31}H_{50}O_5$ or $C_{31}H_{52}O_5$ (found: C, 73·83, 73·99; H, 10·29, 10·30; OCH_3, 6·14 per cent (Weiler, Oxford); C, 73·71; H, 10·13; OCH_3, 6·35 per cent (Manser, Zurich); $C_{31}H_{50}O_5$ requires C, 74·03; H, 10·05; OCH_3, 6·17 per cent; $C_{31}H_{52}O_5$ requires C, 73·74; H, 10·40; OCH_3, 6·14 per cent). The Zeisel determinations confirm beyond doubt the size of the molecule.

Dehydrogenation of asiatic acid with palladium-charcoal or selenium gives a hydrocarbon, the picrate and styphnate of which show no depression of melting point with the corresponding derivatives of sapotalene (1 : 2 : 7-trimethylnaphthalene), the typical dehydrogenation product of the triterpenes[7]. Typical colour reactions of the triterpenes are also positive[8].

Melting points, optical rotations and chemical and physical behaviour of different derivatives of asiatic acid show great similarity with those of other triterpene acids of the β-amyrin group; thus all evidence is in favour of the hypothesis that the carbon skeleton of asiatic acid is the same as that of β-amyrin (cf. Haworth[9], Ruzicka[7]).

Two of the oxygen atoms of asiatic acid are accounted for by the carboxyl group; the three remaining ones form hydroxyl groups. Two of these are in a 1 : 2-glycol group, as oxidation with lead tetra-acetate proceeds readily at room temperature and gives a substance precipitating with 2 : 4-dinitrophenylhydrazine. The presence of such a 1 : 2-glycol group seems to be a new feature for natural triterpene acids (cf. refs. 10, 11). The composition of crystalline acetates obtained from asiatic methyl ester is still under investigation.

The presence of a double bond in asiatic acid is indicated by the formation of a bromo-lactone, similar to that of oleanolic acid or hederagenin; tetranitromethane gives a slight colour with asiatic acid or its methyl ester.

The methyl ester of asiatic acid is very difficult to saponify, like that of similar triterpene acids containing a tertiary carboxyl group. On treating the methyl ester, m.p. 225°, with 15 per cent hydrochloric acid, it is isomerized to a new ester, m.p. 170°.

By chromatography on alumina of the crude methyl ester, m.p. 225°, we have isolated a small quantity of a dimethyl ester, $C_{32}H_{52}O_5$, m.p. 262° (found: C, 73·71; H, 10·23; OCH_3, 12·3. $C_{32}H_{52}O_5$ requires C, 74·35; H, 10·17; OCH_3, 12·28 per cent).

As asiaticoside is a neutral substance, it seems that the sugars are attached to the carboxyl group; the ease of saponification suggests that all four sugar molecules are attached in this way. Lythgoe and Trippett have made analogous observations with centelloside[10].

A comparison of our substance with those prepared in Cambridge from *Centella asiatica* from Ceylon[10,11] has shown that we have certainly different compounds in hand. We are very glad to state that we are keeping in contact with Dr. Lythgoe for the study of these triterpene acids.

Triterpene Acids

Shortly after the announcement in Great Britain[1] that *Centella asiatica* contained a glucose derivative which was active in the treatment of leprosy, we commenced an examination of the plant, with the object of studying the chemical constitution and therapeutic properties of the active material. In this note the results of analyses carried out on dried plant tissue of Ceylonese origin are reported. We are deeply indebted to Dr. J. L. Simonsen, director of the Colonial Products Research Council, for his help in making supplies of this material available to us, and for his interest in these investigations.

No sugar derivative of the type of asiaticoside could be detected, but three triterpene acids were isolated in a pure, though amorphous, condition. It seemed that these were very likely related to the amorphous aglycone of asiaticoside, which was described[2] as giving a red colour with sulphuric acid, a reaction known to be general for triterpene derivatives[3].

The major component of our triterpene mixture, for which we propose the name 'centoic acid', was separated as the sparingly soluble potassium salt (long needles), and purified through the brucine salt, which formed plates from alcohol, $[\alpha]_D = -39°$ (pyridine). The free acid, an amorphous powder, $[\alpha]_D = +44°$ (alcohol), gave analytical data which show it to be a monobasic acid, $C_{30}H_{48}O_6$. It appears to be a normal pentacyclic triterpene acid, closely analogous, apart from its higher hydroxyl content, with oleanolic acid. It gave sapotalene on dehydrogenation with selenium. Although resistant to hydrogenation, it contains a double bond, since with tetranitromethane a yellow colour was obtained with some difficulty[4]. Among its derivatives, the following have been obtained analytically pure, although none of them could be crystallized: a methyl ester, $[\alpha]_D = +36°$ (alcohol), which was stable to hot dilute alkalis and acids; a methyl ester triacetate, $[\alpha]_D = +7°$ (alcohol), which contained one free hydroxyl group (Zerewitinoff); a periodate fission product, $C_{30}H_{46}O_6$, $[\alpha]_D = +92°$ (alcohol), requiring for its formation 1 mole of the oxidant; and a bromolactone. Centoic acid, therefore, contains a tertiary carboxyl and four hydroxyl groups, two of which are present in a cyclic 1 : 2-glycol system.

The other two triterpene acids of dried *Centella* tissue have also been shown to contain a tertiary carboxyl group, an inert double bond, and a 1 : 2-glycol system. That present in the larger quantity, for which the name 'centellic acid' is proposed, was separated by taking advantage of the high solubility of its potassium salt. The brucine salt formed pellet-like needle aggregates, $[\alpha]_D = -44°$ (pyridine), from which the free acid was regenerated as an amorphous powder, $[\alpha]_D = +36°$ (alcohol). Analytical and titration results showed it to be a monobasic acid $C_{30}H_{48}O_6$. As well as the molecular features mentioned above, it probably contains two more hydroxyl groups; but the evidence on this point is not yet clear-cut. The third acid was found present only in minor amounts. Unlike the others, it was precipitated from dilute alcohol by lead acetate. After further purification through the potassium salt (long needles), it was obtained as an amorphous powder, $C_{30}H_{48}O_5$, $[\alpha]_D = +38°$ (alcohol).

It was clearly a question of importance to find whether any of the above acids were identical with the aglycone of asiaticoside, and a short time ago we got into touch with Dr. E. Lederer, who is carrying out an investigation of asiaticoside in Paris. We have compared results on our substances, and Dr. Lederer very kindly provided us with samples of asiaticoside and of the crystalline methyl ester of its aglycone, asiatic acid; we wish to take this opportunity of thanking him for his courtesy. He and his colleagues[5] have shown asiatic acid to be a triterpene acid with properties closely analogous to those of our own acids, and with the molecular formula $C_{30}H_{48}O_5$. A direct comparison has been made with our $C_{30}H_{48}O_5$ acid, and has shown that they are not identical, but isomeric compounds.

We intend to keep in touch with Dr. Lederer, and to extend our investigations on these triterpene acids.

Centelloside

Specimens of *Centella asiatica* grown in Madagascar have been found to contain asiaticoside[1], which is said to have value in the treatment of leprosy[2]. Lederer, Boiteau and their colleagues[3] have shown that asiaticoside is a rhamnose–glucose derivative of a triterpene acid, asiatic acid ($C_{30}H_{48}O_5$). Elsewhere[4] it has been suggested that there may be an 'oxidized form' of asiaticoside present in the fresh plant, which is more readily soluble in water.

Work carried out in this Laboratory[5] has shown that dried *Centella asiatica* tissue from Ceylon contains no asiaticoside or similar compound, but that there are present two triterpene acids $C_{30}H_{48}O_6$, closely related to asiatic acid, and traces of a third isomeric with it. It seemed likely that these sugar-free triterpenes might originate as a result of enzyme action on one or more sugar derivative present in the fresh plant, and evidence is now presented which supports that view.

When alcoholic extracts of fresh Ceylonese plant tissue were analysed, free triterpene acids were found only in amounts too small to permit identification. In one fraction of the extracts, however, combined triterpene was present in considerable quantity. This fraction was purified extensively, until only small traces of free sugar were present (as shown by paper chromatography), but no crystalline material could be obtained from it. We think, nevertheless, that it consists substantially of a single substance, which contains a triterpene acid in combination with a sugar system. Its chemical properties resemble closely those of asiaticoside, and accordingly we suggest for it the name 'centelloside'.

Centelloside forms a pale yellow neutral gum, extremely soluble in water, much less soluble in anhydrous alcohol. It reduces Fehling's solution on warming. Dilute acids liberate from it reducing sugars and a triterpene acid, which was identified as centellic acid[5] by conversion to the crystalline brucine salt. The sugar solution left after removal of centellic acid from the hydrolysate was investigated using a variety of techniques. Glucose was identified by paper chromatography[6], and as the phenylosatriazole derivative[7]. Qualitative and quantitative[8] application of the Seliwanoff reaction showed the presence of a ketose; the optical rotation of the solution identified this as fructose. Rhamnose, which is a component of asiaticoside, was absent. Estimations of total reducing power, and of formaldehyde produced on oxidation with periodate[9], combined with the previous data, gave for centelloside the composition: centellic acid : glucose : fructose = 1 : 10 : 2 (mol.). Since strict proof of the homogeneity of the preparation is lacking, these figures must be regarded as provisional, but they show that centelloside carries a much larger sugar system than asiaticoside, and to this, and to the fructose content, the hydrophilic nature is probably due.

A property of centelloside which calls for special comment is the behaviour with warm dilute alkali, which rapidly sets free the salt of the aglycone, while destruction of the sugar colours the solution yellow. This high lability to alkali makes it unlikely that any part of the sugar is bound glycosidically to triterpene hydroxyl groups, and is sufficient to account for the action on Fehling's solution without assuming a free reducing centre in the sugar system. The aglycone, centellic acid, has no reducing properties.

The neutral nature of centelloside suggests at once that the linkage between sugar and triterpene is of the ester type. It must be borne in mind, however, that the carboxyl of centellic acid is sterically hindered, like that of oleanolic acid, and the behaviour of two synthetic glucose derivatives of the latter has been found to accord with theoretical expectation, and to diverge from that of centelloside. 1-β-Oleanolyl glucose, m.p. 216–218° (decomp.), $[\alpha]_D = + 46{\cdot}5°$ (alcohol), is hydrolysed by acids, but stable to alkalis. 6-(Acetyloleanolyl) glucose, m.p. 235° (decomp.), $[\alpha]_D = + 81°$ (alcohol), although destroyed by alkalis, is stable to acids. The alkali-lability of centelloside remains unexplained, and clarification is being sought, *inter alia*, by the preparation of centellic esters of different sugars.

It is of interest that the Ceylonese variety of *Centella asiatica* apparently produces no asiaticoside but this closely related compound. Whether this reflects a morphological difference, or merely one of habitat or season, we are not competent to decide.

We are indebted to Dr. J. L. Simonsen, director of the Colonial Products Research Council, and to Dr. R. Child, director of the Coconut Research Scheme, Lunuwila, Ceylon, for making the fresh plant material available to us; the plants were identified botanically at the Department of Agriculture, Peredeniya, Ceylon.

ELEMENTARY BODIES OF VARICELLA AND HERPES ZOSTER

By J. L. FARRANT
Division of Industrial Chemistry,
Council for Scientific and Industrial Research, Melbourne
AND
J. L. O'CONNOR
Commonwealth Serum Laboratories,
Commonwealth Department of Health, Melbourne

DESPITE the prevalence of varicella and herpes zoster, little information is available concerning the infective agents themselves, since susceptible experimental animals providing adequate quantities of the viruses have not been found. Optical microscopical observations on the morphology and size of stained varicella virus have been made by Aragão[1], Paschen[2], Amies[3] and, more recently, by van Rooyen and Illingworth[4]. The last-named workers describe the infective agent as having a diameter of 1,250–1,750 A., and as being appreciably smaller than the elementary bodies of vaccinia and variola. Particles of the size stated are at the limit of resolution of the optical microscope, so little information is available concerning the elementary body itself.

Ruska[5] has reported an electron microscopic study of these viruses in a journal not available to us. Ruska's work was published before the 'shadow-casting' technique of Williams and Wyckoff[6] was devised, but we have used this method in a study of these viruses. The electron microscope used was an R.C.A. Model *EMU*.

The material used was fluid withdrawn from early vesicles in cases of chickenpox and shingles and variously diluted with normal saline to one-fifth to one-twentieth of the original concentration. Approximately 0·01 c.c. of the diluted fluid was allowed to evaporate to dryness on a collodion film stretched across a wire-mesh specimen screen, washed with distilled water to remove soluble salts and then 'shadow-cast' with platinum as recommended by Williams and Backus[7]. A thickness of c. 7 A. of platinum was deposited at such an angle that the shadow-lengths were 3·9 times the heights of the corresponding particles.

In fluid direct from the vesicles of four of the five cases of chickenpox examined, a number of bodies of regular size and shape were seen. The identity of these bodies with the causative agent of varicella was established by making two sets of preparations. The first (*a*) consisted of equal volumes of vesicle fluid diluted one-in-five with normal saline and of serum similarly diluted, taken from a patient 24 hours after the onset of an attack of chickenpox. Set (*b*) was similarly prepared except that the serum used was taken from the same patient on the eighth day of the disease. Both mixtures were allowed to stand for one hour at 22° C. before a portion was transferred to specimen screens and dried. Preparation (*a*) showed a uniform dispersion of particles which occurred singly; by contrast, preparation (*b*) showed considerable aggregation of the particles (Fig. 1).

Only two cases of herpes zoster were available for examination, and the vesicle fluid of one of these was found to contain particles indistinguishable in size

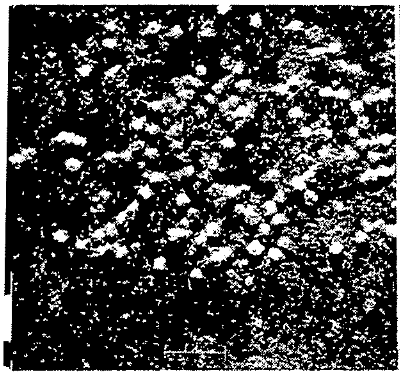

Fig. 1

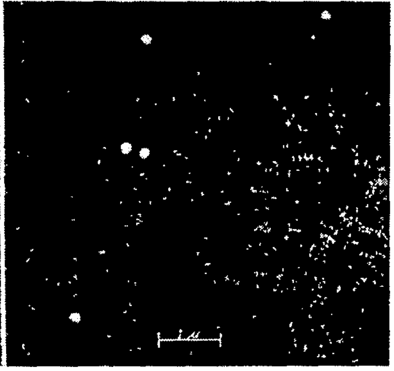

Fig. 2

Fig. 1. Varicella virus agglutinated with convalescent serum. Shadow-cast with platinum. Shadow ratio, 3·9

Fig. 2. Varicella virus fixed with 0·5 per cent osmic acid. Shadow-cast with platinum. Shadow ratio, 3·9

and shape from those observed in varicella. In view of the well-known fact that an attack of either herpes zoster or of varicella affords immunity against the other, attempts to observe agglutination of herpes zoster virus by convalescent serum from a case of varicella were made. Once again the convalescent serum caused much more marked aggregation of the virus than did the onset serum.

The profile of the virus particles shown in the micrographs is roughly circular; but measurements of shadow-lengths (see table) indicate that they are not truly spherical but oblate. In fact, the appearance of the particles is that of caps of ellipsoids, suggesting that the particles have collapsed to various extents on drying at room temperature. Evidence in support of this view was obtained by fixing the particles by the addition of osmic acid or formalin to the virus suspensions in saline. When so fixed, the virus particles approach more closely to the spherical form when dried (Fig. 2). As the micrographs yielded insufficient information for the calculation of the volumes of the unfixed virus particles as caps of ellipsoids, they were treated as caps of spheres and their volumes were found to agree with those of the fixed particles treated as ellipsoids (see table).

	No. of particles measured	Mean diameter (A.)	Mean height (A.)	Mean volume (10^6 A.^{3})
Varicella virus	77	2420±30	730±15	1880±60
Varicella virus and onset serum	30	2420±30	750±30	1950±90
Varicella virus and convalescent serum	45	2450±40	800±20	2150±80
Varicella virus and 5 per cent formalin	14	1860±70	1030±40	1870±160
Varicella virus and 0·5 per cent osmic acid	14	1750±35	1180±50	1890±110
Herpes zoster virus	19	2530±80	790±30	2240±160

Hodge[8], of this Laboratory, has observed a similar effect on fixing influenza virus particles with phosphotungstic acid. Similar observations have been made by Dawson and McFarlane[9] on the brick-shaped particles of vaccinia virus. They found particles dried at room temperature had the same lateral dimensions as freeze-dried particles but were only half the height. Particles fixed with osmic acid had the same volume as the particles dried at room temperature; but all dimensions were 20 per cent less than those of freeze-dried particles. It appears that fixed particles retain their true shape to a greater extent than those dried at room temperature, but freeze-drying is required if the true shape and size are sought.

Statistical treatment shows that the untreated varicella virus particles are significantly smaller than those treated with convalescent serum and are also smaller than herpes zoster virus particles. However, our preparations contained too much extraneous protein material to allow any real significance to be attached to these differences. The mean particle dimensions and their standard errors given in the table depend on magnification calibration obtained by means of interferometrically measured glass fibres as described by Farrant and Hodge[10].

Virus particles treated with phosphotungstic acid and osmic acid show areas of differing densities suggesting internal structure, but no evidence of this could be seen in the unstained particles.

The identity of these bodies with the causative agent of varicella is not conclusively established, as it has not been possible to attempt the reproduction of the disease by purified suspensions of them. It is not, therefore, possible to satisfy Koch's postulates; but the occurrence of the particles in the vesicle fluid of four out of five patients suffering from chickenpox, and the development of serum agglutinins for the bodies observed, during the course of the disease, give a high degree of probability that they are the cause of chickenpox.

Since this work was completed, we have received a paper by Rake and Nagler[11] showing electron micrographs of varicella virus. The particle dimensions in the horizontal plane, given by them, differ from those obtained by us; but it is evident from our own observations that size depends, to a great extent, upon the mode of preparation of the specimen for examination.

We desire to thank Dr. W. Stephenson and Dr. A. Ferris, of the Infectious Diseases Hospital, Fairfield, Melbourne, who kindly supplied the specimens for investigation. We also thank Dr. A. L. G. Rees, of the Division of Industrial Chemistry, for his interest in this work.

MECHANICAL WEAR

SUMMER CONFERENCE AT THE MASSACHUSETTS INSTITUTE OF TECHNOLOGY

A SPECIAL summer conference on mechanical wear was held at the Massachusetts Institute of Technology, Cambridge, Mass., on June 14–16, under the joint sponsorship of the American Society of Mechanical Engineers, the General Motors Corporation and the Chrysler Corporation, together with the Institute itself. The object of the conference was to take stock of the present knowledge and theories on this very important subject so that the most profitable directions of future research might be more clearly indicated. The absence of any general meeting on the subject in either the United States or Europe during recent years made this especially desirable.

The papers presented and accompanying discussion covered laboratory and service experience on wear in internal-combustion engines, steam turbines, brake materials, journal bearings, gears, electric brushes (in the absence of electric currents), surface plates and cutting tools. In addition, results of laboratory tests on laboratory machines simulating some of these service operations and also on specially designed wear-test machines were reported. Specifically excluded from consideration at the conference were the subjects of cavitation erosion by liquids and the wear of current-carrying electric contacts.

It was the general consensus that the wear phenomenon is exceedingly complex and depends on numerous factors. Some of these factors were discussed in considerable detail by one or more of the speakers. They included hardness, fatigue strength, gas adsorption, chemical reaction, and viscosity. These discussions were too long to report here in detail, but the following notes indicate matters which were especially interesting to those present.

F. P. Bowden and D. Tabor (University of Cambridge) summarized the various ways in which rubbing surfaces can operate, depending on the quantity and type of lubricant present (in other words, full-fluid, boundary or dry), and they cited various evidence for presence or absence of metal-to-metal contact in each of the three regions. The evidence showed, on one hand, intermittent contact even under conditions of sliding hydrodynamic lubrication, but on the other hand the transmission through thick oil-films of compressive stresses exceeding the yield point of the metal without direct solid contact. In a separate connexion they showed that fatty acids, which are supposed to attack metal surfaces chemically to form metal soaps which are very effective boundary lubricants, will not attack these same metal surfaces if the latter have not previously been exposed to air and moisture. R. Savage (General Electric Research Laboratory) described his recent findings on the mechanism of the lubrication and wear of graphite. He found that the presence of oxygen or water vapour was necessary for graphite to lubricate in its familiar manner. In the absence of these gases it wears extremely badly, producing a fine dust having strong surface-active properties.

E. S. Starkman and A. G. Cattaneo (Shell Development Company) showed that the corrosive wear of piston rings increased with the amount of sulphur in the fuel, owing to formation of sulphur trioxide; it increased with the amount of tetra-ethyl lead in the fuel owing to the simultaneous presence of the halogen scavenger, and it increased sharply below the dew-point of the water vapour in the combustion gas mixture owing to the formation of carbonic acid. R. Holm (Stackpole Carbon Company) proposed a relation, for the purpose of correlating wear measurements, which involves the hardness of the rubbing surfaces. He also discussed the relation of this contact hardness, as measured by an indenter, to the yield point of the metal. In addition, he showed that the measured contact-hardness depended on the size of the indenter.

H. Blok (Royal Dutch Shell, Delft) showed that the failure of gear teeth under exaggerated impact loading depended much more on the viscosity of the lubricant than on its oiliness or extreme-pressure characteristics. This was attributed to the ability of viscous liquids to withstand suddenly applied compressive loads. J. O. Almen (General Motors Research Laboratories) discussed the wear of gear teeth and especially that type known as scoring or welding wear. He showed a correlation between failure due to this type of wear and the product of the factors of compressive stress, sliding velocity, and the length of time the teeth are in contact. E. Buckingham (Massachusetts Institute of Technology) and G. J. Talbourdet (United Shoe Machinery Corporation) reported data on the failure of gear materials from another type of wear, namely, pitting fatigue.

J. H. Dedrick (University of Cincinnati) and John Wulff (Massachusetts Institute of Technology) described friction and wear measurements on certain ternary-bronze powder-metallurgy brake-materials containing lead, graphite and silica. They found that only a small region on the corresponding ternary diagram gave alloys having suitable characteristics as regards wear-rate and quiet operation. This area is limited to compositions containing both lead and graphite, but silica is not necessary. R. G. Larsen (Shell Development Company) tabulated and discussed all the possible adsorption and chemical reactions that could take place between the rubbing metal surface and its gas or lubricant environment. These were found to be quite numerous and sometimes complex. C. M. Allen (Battelle Memorial Institute) reported qualitative information on the minimum oil-film thickness in a fluid-lubricated journal-bearing just prior to failure. He measured the electric break-down potential of the oil film and showed that this often gave warning of impending failure.

The complete proceedings of the conference will be published shortly by the American Society for Metals, Cleveland, Ohio. J. T. BURWELL, JUN.

ORIGIN OF THE SOLAR SYSTEM

PROF. HAROLD JEFFREYS has published a paper in which he examines a number of theories proposed to explain the origin of the solar system[1]. In the early part of the paper he points out that the resonance theory of the origin of the moon can no longer be maintained; and, in fact, it was shown many years ago to be quite untenable for various reasons, though it is still referred to in popular works as a possible explanation of the existence of our satellite. Dealing with the origin of the planetary system, he refers to his earlier view of a collision between the visiting star and the sun, which appeared to make some successful quantitative predictions, but which Russell showed to be dynamically unsound. Lyttleton's theory that at the time of the encounter with the visiting star the sun was a double star, and that the encounter was with the companion, seemed to offer a way out of the difficulty. On this theory there was the possibility that the visiting star and the companion would escape from the neighbourhood of the sun, and yet leave a considerable fraction of the ejected matter revolving around the sun. Nevertheless, as Jeffreys shows, in all catastrophic theories there is a fundamental difficulty. In Jeans's tidal theory it was assumed that the elongated filament would be gravitationally unstable and would break up into a number of pieces—a view which is difficult to maintain if the matter ejected from the sun (or its companion) had an initial high temperature. Jeffreys investigated a number of cases nearly twenty years ago and showed the difficulties in the view that the gravitation of the mass could maintain equilibrium, though there was the possibility that adiabatic cooling during expansion would lead to the formation of liquid drops at an early stage, and thus the pressure might be relieved before the velocities became uncontrollable. More recently, Spitzer dealt with the same problem and concluded that during the expansion of cylindrical and ribbon-like filaments these would disappear completely.

Another difficulty arises in connexion with the compositions of the planets; it is interesting to note that the greater densities of the inner planets find a natural explanation if they were originally gaseous, because the greater masses of the outer zones would retain lighter materials, which would be lost by the smaller ones. If bodies of different masses were set free suddenly in a vacuum, we should expect that there would be these differences in composition; if gradual evolution took place, the materials would be mixed and the compositions nearly uniform. Hence the present condition of the inner and outer planets favours a catastrophic theory which, as has just been pointed out, is itself open to very serious objections. At this stage Jeffreys discusses some recent results on possible modes of disruption of rotating bodies, and deals with the question of a disrupted planet giving rise to two or more independent planets, thus accounting for the differences of composition among the inner planets. Originally there might have been one or two bodies which acquired too rapid a rotation for stability as they condensed, but before the development of instability the central cores would have had time to form. Lyttleton suggested that all the planets could be brought into this scheme, and secondary disturbances, like a splash, might be associated with the separation. Some pieces might continue with each of the main bodies, giving rise to satellites, while others might become independent of both bodies, forming the terrestrial planets and the moon. In 1941 Lyttleton showed that a planetary system might be formed by fission without any external disturbance. Starting with a triple star with two very close companions, he showed that if these coalesced the angular momentum would be sufficient to produce fission and make them separate indefinitely. The two parts might both escape from the third body (the sun) while leaving part of the splash to be captured by it. The accretion of interstellar matter would cause the coalescence of the two companions, and, as Jeffreys admits, there is no obvious quantitative objection to this theory except that just referred to, namely, the high initial temperatures of the planets.

Although the existence of small bodies presents a difficulty in all theories, owing to their feeble gravitational pull on their material, and Lyttleton's fission theory of the planets offers some hope of explanation as the fission was supposed to have taken place after liquefaction, there is another possible explanation. A liquid or solid, however small, will grow if immersed in a gas, provided that the density of the gas exceeds the saturation vapour density at the actual temperature. A. L. Parson has dealt with this problem[2], and it seems that even with the present small density of interstellar matter, iron, calcium oxide, magnesium oxide and silicon dioxide are capable of condensing; but water, methane and ammonia would be unlikely to condense near Jupiter and Saturn at the probable densities—about 10^{-15} gm. per c.c. Jeffreys admits that Parson's results answer one of his chief objections to the planetesimal theory that the small bodies would collide and volatilize one another before they could produce any notable effect on the planets. If they did, the vapour would condense again and form new dust, the accretion of the planets proceeding. Hoyle has examined the question of accretion by the planets[3] and finds that it would take place at an increasing rate as the planet became larger; and if a condensation reached the mass of the earth, it would grow rapidly to attain a mass of the order of that of one of the major planets.

Other theories on the formation of the planets and satellites are considered; but Jeffreys is not satisfied with any of the existing theories. Thus he says: "But many notable advances have been made in the last twenty years, and the problem is to decide which of them are relevant to the origin of the solar system".

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, February 14

INSTITUTION OF THE RUBBER INDUSTRY, MIDLAND SECTION (joint meeting with the BIRMINGHAM SECTION of the ROYAL INSTITUTE OF CHEMISTRY, at the James Watt Memorial Institute, Great Charles Street, Birmingham), at 7 p.m.—Dr. H. W. Melville, F.R.S.: "The Degradation of High Polymer Substances".

INSTITUTION OF THE RUBBER INDUSTRY, PRESTON SECTION (joint meeting with the ROYAL INSTITUTE OF CHEMISTRY, the SOCIETY OF CHEMICAL INDUSTRY, and the BRITISH ASSOCIATION OF CHEMISTS at the Victoria and Station Hotel, Preston), at 7 p.m.—Dr. W. J. S. Naunton: "Natural and Synthetic Polymers" (with special reference to Rubber and Synthetic Fibres).

Tuesday, February 15

SOCIETY OF PUBLIC ANALYSTS AND OTHER ANALYTICAL CHEMISTS, BIOLOGICAL METHODS GROUP (joint meeting with the AGRICULTURAL GROUP of the SOCIETY OF CHEMICAL INDUSTRY, in the Chemistry Department, Royal College of Science, Imperial Institute Road, London, S.W.7), at 2.30 p.m.—Discussion on "The Evaluation of Selective Weedkillers" (to be introduced by Dr. M. A. H. Tincker).

ROYAL INSTITUTION (at 21 Albemarle Street, London, W.1), at 5.15 p.m.—Sir Edward Salisbury, F.R.S.: "Types of Distribution in the British Flora". (Further Lectures on February 22, March 1 and March 8.)

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.15 p.m.—Dr. A. Schweitzer: "Reflexogenic Areas of the Vascular System".* (Further Lectures on February 22, March 1, March 8 and March 15.)

SOCIETY OF CHEMICAL INDUSTRY, CHEMICAL ENGINEERING GROUP (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Prof. T. R. C. Fox: "Technical Education".

INSTITUTION OF THE RUBBER INDUSTRY (at Caxton Hall, Caxton Street, London, S.W.1), at 7 p.m.—Dr. C. Bondy: "The Colloidal Aspect of Rubber Latices"; Dr. W. H. Bodger: "The Applications of Various Types of Rubber Latex".

SOCIETY FOR VISITING SCIENTISTS (at 5 Old Burlington Street, London, W.1), at 7.30 p.m.—Discussion on "The International Organisation of Science". (Speakers: Prof. M. J. Sirks, Prof. F. J. M. Stratton, F.R.S., Dr. Joseph Needham, F.R.S., and others.)

Wednesday, February 16

Royal Meteorological Society (at 49 Cromwell Road, London, S.W.7), at 5 p.m.—Discussion on "Large-scale Vertical Motion in the Atmosphere".

Royal Microscopical Society (in the Hastings Hall, B.M.A. House, Tavistock Square, London, W.C.1), at 5.30 p.m.—Dr. R. Barer: "Reflecting Microscopes—Past, Present and Future".

Royal Institute of Chemistry, London and S.E. Counties Section (at 30 Russell Square, London, W.C.1), at 6.30 p.m.—Dr. G. M. Bennett, F.R.S.: "The Work of the Government Laboratory".

Oil and Colour Chemists' Association, London Section (at Manson House, 26 Portland Place, London, W.1), at 7 p.m.—Dr. D. V. N. Hardy: "Silicones".

Royal Statistical Society, North-Eastern Group of the Industrial Applications Section (at the Chemical Industries Club, 18 Lovain Place, Newcastle-upon-Tyne), at 6.30 p.m.—Mr. E. D. van Rest: "Probability and the Experimenter". (To be repeated on Thursday, February 17, at the William Newton School, Norton, Stockton-on-Tees, at 7.15 p.m.)

Society of Chemical Industry, Plastics Group (joint meeting with the London Section of the Plastics Institute, at the Waldorf Hotel, Aldwych, London, W.C.2), at 6.30 p.m.—Dr. H. M. Stanley: "Petroleum Hydrocarbons as Raw Materials for the Plastics Industry".

Thursday, February 17

University of London (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Dr. G. Burniston Brown: "The New Philosophy of Science".*

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Institution of Mining and Metallurgy (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Mr. Jack Spalding: "Ground Control—Theory and Practice".

London Mathematical Society (at the Royal Astronomical Society, Burlington House, Piccadilly, London, W.1), at 5 p.m.—Prof. P. Erdös: "An Elementary Proof of the Prime-Number Theorem".

British Glaciological Society (at the Royal Geographical Society, Kensington Gore, London, S.W.7), at 5.15 p.m.—Discussion on "The Origin of Ice Pyramids and Dirt Cones on Glaciers".

Chemical Society, North Wales Section (joint meeting with the University College of North Wales and University of Liverpool Chemical Societies, in the Department of Chemistry, University College of North Wales, Bangor), at 5.30 p.m.—Dr. W. H. J. Vernon: "Corrosion, the Study of Surface Reactions on Metals".

Chemical Society, Sheffield Section (joint meeting with the Sheffield University Chemical Society, in the Chemistry Department Lecture Theatre, The University, Sheffield), at 5.30 p.m.—Prof. W. F. K. Wynne-Jones: "Hydrogen Peroxide as an Ionizing Solvent".

University of London (in the Department of Civil, Mechanical and Chemical Engineering, King's College, Strand, London, W.C.2), at 5.30 p.m.—Mr. D. H. Lee: "Foundations with reference to Soil Mechanics and Mining Subsidence".*

British Institution of Radio Engineers, London Section (at the Royal Empire Society, Craven Street, Strand, London, W.C.2), at 7 p.m.—Discussion on "Electronic Equipment for the Engineer".

Textile Institute (at 16 St. Mary's Parsonage, Manchester), at 7.15 p.m.—Mr. A. W. Bayes: "The Function of Testing in Production".

Textile Institute, Burnley Branch (at the Mechanics' Institute, Manchester Road, Burnley), at 7.15 p.m.—Mr. A. M. Robertson: "Fibreglass and its Uses".

Chemical Society (in the Main Chemistry Lecture Theatre, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 7.30 p.m.—Prof. Dr. V. Prelog (Zurich): "Recent Developments in the Chemistry of Macrocyclic Compounds".

Royal Society of Tropical Medicine and Hygiene (at Manson House, 26 Portland Place, London, W.1), at 7.30 p.m.—Dr. A. F. Mahaffy: "The Epidemiology of Yellow Fever in Central Africa".

Friday, February 18

Biochemical Society (at St. Thomas's Hospital Medical School, London, S.E.1), at 2 p.m.—Scientific Papers.

Institute of Navigation (at the Royal Geographical Society, Kensington Gore, London, S.W.7), at 2 p.m.—Symposium on "Operational Aspects of Marine Radar".

Association of Applied Biologists (in the large Chemistry Theatre, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 2.15 p.m.—Annual General Meeting; Mr. W. C. Moore: "The Significance of Plant Diseases in Great Britain" (Presidential Address).

Eugenics Society (at Manson House, 26 Portland Place, London, W.1), at 5 p.m.—Rt. Rev. the Lord Bishop of Birmingham, F.R.S.: "The Mixing of Races and Social Decay" (Galton Lecture).*

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Discussion on "Rotary, Oscillating and Reciprocating Seals" (to be opened by Mr. T. E. Beacham and Mr. F. H. Towler).

Institute of Physics, Manchester and District Branch (in the New Physics Theatre, The University, Manchester), at 7 p.m.—Dr. F. P. Bowden, F.R.S.: "Friction".

Society of Instrument Technology, Midland Section (at the Arden Hotel, New Street, Birmingham), at 7 p.m.—Mr. N. F. Astbury: "Some Instruments for Iron Testing".

Society of Glass Technology, North-West Section (at the Gas Showrooms, Radiant House, St. Helens), at 7.15 p.m.—Mr. W. J. R. Merren: "The Application of Electronics in Glass Manufacture and Glass Research".

Royal Society of Medicine, Radiology Section (joint meetin with the British Institute of Radiology and the Faculty o Radiologists, at 1 Wimpole Street, London, W.1), at 8.15 p.m.—Discussion on "The Physical, Cytological and Medical Aspects o Protection from Ionizing Radiations with Special Reference to th Use of High Voltage X-Rays and Radio-Isotopes" (to be opened b Sir Ernest Rock Carling, Dr. Katharine Williams and Mr. Marley).

Royal Institution (at 21 Albemarle Street, London, W.1), a 9 p.m.—Prof. Homer A. Thompson: "The Agora of Ancient Athens a Study in Archæological Restoration".

Saturday, February 19

Physical Society (in the Department of Natural Philosophy, The University, Edinburgh), at 10 a.m.—Scientific Papers.

Royal Institute of Chemistry, London and S.E. Countie Section (at the University, Reading), at 3 p.m.—Prof. F. E. Simon F.R.S.: "Experiments on Solid Helium".

APPOINTMENTS VACANT

Applications are invited for the following appointments on o before the dates mentioned:

Lecturer in Biology—The Dean of the Medical College, St Bartholomew's Hospital, West Smithfield, London, E.C.1 (February 21).

Principal Scientific Officer or Senior Scientific Officer for research on problems of heat exchange, Senior Scientific Officers (2) for research on (*a*) fluid mechanics and (*b*) kinematics and mechanisms, a Senior Experimental Officer or Experimental Officer to prepare detailed designs of plant, equipment and apparatus for a new hydraulic machinery research laboratory, and a Senior Experimental Officer (Engineer) for general duties connected with the development of new laboratories including an engineering workshop; in the Mechanical Engineering Research Organisation of the Department of Scientific and Industrial Research—The Secretary, Civi Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2388 (February 22).

Principal Scientific Officers and Experimental Officers in the Medical Statistical Department of the Directorate of Hygiene in the War Office—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2390 (February 22).

Librarian in the Department of the Scientific Adviser to the Army Council at the War Office—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2396 (February 24).

Lecturer in Mathematics at the Military College of Science, Shrivenham, near Swindon—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.335/48A (February 26).

Veterinary Research Posts (Principal Scientific Officer or Senior Scientific Officer grades, unestablished) at a Ministry of Supply research and development establishment in Wilts—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting G.8/49A (February 26).

Chair of Geology—The Secretary, The University, Birmingham 3 (February 28).

Principal Scientific Officers, Senior Scientific Officers and Scientific Officers (unestablished, with good honours degree or equivalent in mathematics, physics, mechanical or aeronautical engineering), at the Royal Aircraft Establishment, Farnborough—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.451/48A (February 28).

Senior or Junior Physical Chemists for the British West Indies Sugar Research Scheme—The Secretary, Imperial College of Tropical Agriculture, 40 Norfolk Street, London, W.C.2 (February 28).

Leverhulme Research Fellowships—The Secretary, Leverhulme Research Fellowships, 7 Bedford Row, London, W.C.1 (March 1).

Scientific Officer (zoologist) to carry out research on fish and fisheries under the personal supervision of the Director—The Secretary, Scottish Marine Biological Association, 185 St. Vincent Street, Glasgow, C.2 (March 1).

Director of the Association, a Deputy Director and Head of the Department of Applied Physics, and a Psychologist, at the Ahmedabad Textile Industries' Association, Ahmedabad—The Office of the High Commissioner for India, Scientific Liaison Officer, India House, Aldwych, London, W.C.2 (March 1).

Lecturer in Educational Psychology—The Registrar, University College, Hull (March 1).

Senior or Junior Physical Chemists at the Imperial College of Tropical Agriculture, Trinidad—The Secretary, Imperial College of Tropical Agriculture, 40 Norfolk Street, London, W.C.2 (March 5).

I.C.I. Research Fellowships in Biochemistry, Chemistry, Engineering, Pharmacology or Physics—The Secretary of University Court, The University, Glasgow (March 15).

Chair of Philosophy, and Lectureships in Mathematics, Botany and Chemistry, at the University College of the Gold Coast—The Secretary, Inter-University Council, 8 Park Street, London, W.1 (March 19).

Director—The Secretary, East Malling Research Station, East Malling, Maidstone, Kent (March 31).

Biochemist with research experience for research and development work of physico-chemical nature in relation to human plasma products, and a Junior grade for work of an immuno-chemical nature; at the Institute's Elstree laboratories—The Secretary, Lister Institute, Chelsea Bridge Road, London, S.W.1.

Physical Chemist—The Secretary, Research Association of British Rubber Manufacturers, 105–7 Lansdowne Road, Croydon, Surrey.

Assistant Chemist at the Courtauld Institute—The Secretary, Middlesex Hospital Medical School, London, W.1.

ORGANISATION AND MANAGEMENT IN NATIONAL INDUSTRIES

THE general lessons to be learned from the experience of the coal industry under national ownership in Britain are clearly of great importance and wide interest in view of the prominent position in the Government's programme for nationalization of industry. A certain amount of material is already available. Sir Charles Reid contributed a series of important articles to *The Times* last November, and now a useful report, "The Organisation of the Coal Board", by Colonel C. G. Lancaster, has been issued by the Conservative Political Centre. The National Coal Board has prepared a statement on what it describes as the "main recommendations" of the committee set up under the chairmanship of Sir Robert Burrows to investigate the organisation of the Board; the reason given for not publishing the complete report is that it "would not be in the best interests of the industry". This ignores the large section of public opinion which is concerned to observe impartially the results of this great experiment in public ownership, with the view of remedying whatever defects of organisation, equipment or other matter that may be revealed, and of seeing that any further experiments in nationalization should be able to avoid the same mistakes. The decision to withhold full publication consorts ill with a Government policy which has established the British Institute of Management and is pressing for higher standards of management in industry.

It is the general lessons to be drawn from the experience of the coal industry that are so important at the present time; nevertheless, the question of public responsibility and accountability which public ownership implies should not be allowed to go by default.

From what has been disclosed of the recommendations of the Burrows' Committee, it seems clear that the original organisation of the National Coal Board was defective; and that some of its difficulties would have been avoided had a more decentralized structure been adopted at the start and one less calculated to destroy the sense of individual responsibility in an industry which, like many others, has depended on personal energy and enterprise. Even with the most perfect organisation, it will not be easy under public ownership to preserve the sense of individual responsibility which is so important a factor in preventing the rise of costs, the elimination of waste of materials or of man-power. The proposals made by Sir Charles Reid in his articles are designed primarily to provide an organisation which insists on personal responsibility at all levels, so that waste in whatever form can be immediately checked and eliminated. Incidentally, they would make the scientific staff merely advisory to the twenty-six operating bodies which would replace the present eight divisions, with the management of research stations as their major work. As Sir Charles observes, character develops with responsibility, and a man will only give of his best when he has complete charge of his job and is trusted to perform it.

The similarities between the internal and the external criticisms of the organisation of the National Coal Board do not conceal a difference in the emphasis laid on the bearing of organisation on the present state of the industry. The transfer of ownership has not given the output that was expected or is essential, and mechanical improvements have not brought productivity above even the pre-war level. Unsatisfactory output and a high level of absenteeism have, moreover, been accompanied by the marketing of very inferior coal, which may to some extent falsify even the output figures, low as they are.

Differences of opinion may exist as to the exact responsibility of organisation for such weaknesses, and as to the most appropriate measures by which to remove them in the coal industry itself. Nevertheless, there is general agreement that there has been confusion in the working of the Board's policy, faulty liaison, lack of clarity in the 'channel of command', and an absence of full understanding and mutual confidence between the different units of authority and between the different departments. The public interest, therefore, demands that there should be full and public discussion of this problem of the organisation of nationalization in industry in time to prevent the repetition of like mistakes elsewhere. Nor can it be said that this is simply a matter of organisation. It is equally a question of management. Fundamentally, it is a question of how to secure the leadership in industry which will simultaneously ensure efficient production, the loyal and full co-operation of all engaged in it at every level, and a high standard of service to the general public which uses the products of industry.

Much is involved in this question of leadership in a free society. It involves industrial psychology as well as the study of administration. The problem of incentives is not one in which we are content just to study people at work and the relations between them and the situation at work: we must study also the people who work as individual human beings, whether they are managers, technicians, craftsmen, skilled or unskilled labourers. We must also study the society as a whole in which they are working; for its conditions can affect incentives just as strongly as those group relations within the factory on which the investigations at the Western Electric Co. have laid such stress.

There, indeed, we are passing into the wider field of social science, and are concerned with moral and spiritual as well as with material factors. This is one reason why the report of the Present Question Conference at Magdalen College, Oxford, last August on "The Problem of Leadership in a Free Society"* is so timely. Here once again is reiterated the need to take full account of the total social and industrial situation in which the workers in any particular firm or organisation find themselves. Incentives and deterrents, for example, can only be judged against the background of social reality, taking account both of the social setting and of individual attitudes. It is scarcely possible to avoid in modern industry some degree of remote control. The real question is the extent of such control, and how to secure, simultaneously, adaptability and flexibility and the spontaneous co-operation which is vital in efficient production.

The major part of the third Present Question Conference was devoted to a discussion of leadership in industry initiated by Mr. W. B. D. Brown, the other major contributions being those of Prof. D. M. Mackinnon on the leader and the idea, and of Dr. J. H. Oldham on leadership and society. All alike put men and women as persons into the centre of the problem, but stress the need for reconciling the needs of the individual with those of the smaller and larger groups of which the individual is a unit and which permit both the expression of individuality and the growth of units and social groups. Much that Mr. Brown has to say about leadership in industry, particularly on joint consultation and the like, is to be found in other words in Mr. F. J. Burns Morton's recent book "Team-work in Industry"; but he brings out even more clearly the way in which with the passing of autocracy there must be a keener and more widely diffused sense of responsibility among all engaged in industry.

That is the condition of industrial democracy; and Prof. Mackinnon, pursuing much the same theme, shows how this question of freedom in industry is linked up with the idea of service. It is implicit in the idea of leadership; and while both industry and society require leadership of all kinds and at all levels, it is leadership of a type, not indeed unknown or even rare in history, but alien from that in which the idea of domination or autocracy prevails. It is the leadership of which Arthur Bryant wrote in "Years of Victory": not a mere matter of transmitting orders but of evoking the will to serve. It is the quality which, as Dr. Oldham insists, inspires men and women, and secures the constant but spontaneous co-operation of others in raising the standards of society and in the pursuit of excellence. It means leaders who are capable of understanding the common or group mind, and who, while taking account of scientific and technical factors in industrial or social problems, are not dominated by them.

Dr. Oldham's words here need to be weighed by those who are inclined to exaggerate the importance of a scientific approach, and to look to the use of the scientific method alone to solve our social and political problems. Dr. Oldham recognizes our great need of more knowledge especially in the field of the social sciences, and that there are important problems capable of technical solutions; but he insists that fundamental problems of human society to-day are not the technical problems. They are problems of equilibrium between competing interests, the distribution of power and the restraint and responsible exercise of power. They require for solution not knowledge or technique but the wisdom which is the mark of the statesman.

The question of moral and spiritual power arises here, and that involves a question of values—that persons are prior to things. The Present Question Conference is a challenge to the materialism and the false scale of values which have been responsible for so much that is wrong and weak in industry to day. Some of these weaknesses are shown in greater detail by Mr. Burns Morton in the book already referred to. They will not be eliminated altogether by new techniques of co-operation or forms of organisation, but only as some moral or spiritual force takes possession of individuals and groups and binds them together in the same sense of fellowship and service to a great cause as we witnessed in Britain under great leadership in the summer of 1940.

---

* Question. Vol. 1, No. 2. Winter, 1948. (Present Question Conference, Ltd.) 2s. 6d.

This is no new conception of leadership. Colonel L. Urwick has brilliantly expounded Mr. Ordway Tead's definition of leadership as winning the will to co-operate from those whose co-operation is needed, and making the purposes of the joint undertaking explicit and continuously attractive to those who share the burden of attaining them. We have still far to before that conception finds adequate expression in industry, whether nationalized or not, and it is a conception that applies to leadership both at the lower levels and at the highest ranks of management. The social scientist and industrial psychologist have undoubtedly still much to contribute in this field and may help us to understand more clearly the causes of past failure and to devise new ways or techniques of overcoming them. But what is needed is not so much new knowledge as the wise and resolute application of much that is already known and even familiar. We need the driving force of a common purpose and a common ideal, and it is in this conviction that Sir Stafford Cripps writes in his foreword to the report of the Present Question Conference: "We can hope for but little from our future unless we are prepared to place behind all our efforts our full spiritual power and force. More and more it is brought home to me in all my work that it is the moral strength of high spiritual standards that must give us the courage and determination to solve our many problems in the social, economic and political fields. Let us not be afraid to proclaim and to act upon the faith that is ours, faith in the power of the spirit of man to control the material resources at his disposal."

LORD RUSSELL'S THEORY OF KNOWLEDGE

Human Knowledge

Its Scope and Limits. By Bertrand Russell. Pp. 538. (London: George Allen and Unwin, Ltd., 1948.) 18*s*. net.

LORD RUSSELL interprets human knowledge narrowly. He deals with scientific knowledge and takes it to be, for the most part, mathematics and physics, along with the cruder common-sense knowledge on which they are based. He admits, indeed emphasizes, that psychology is in some respects a distinct discipline, which has to be taken into account and has a certain primacy. Granted these limitations, which are certainly convenient for exposition, the book is a masterly and comprehensive piece of work. It contains, in the reviewer's opinion, far the best treatment that has yet appeared of the problems of inductive generalization. This is the central theme of the book and one on which Lord Russell has barely touched in previous books. There is a discussion of language (Part 2) intended to clear up ambiguities and dispose of fallacies, not very different from that in his "Inquiry into Meaning and Truth". There is a valuable section on probability (Part 5) which is intended to specify the useful but subordinate part which the mathematical theory of probability plays; subordinate, because mathematical theory cannot be applied unless the basic problem of induction is taken as solved already, and because another non-mathematical notion of 'credibility' is required.

The central problem may be stated as follows. It must be granted that the sciences exist and form a body of knowledge which, though incomplete and largely tentative, is growing and claims to be valid; not in the sense of being infallible, but immeasurably better than any alternative. The claim to validity cannot be treated solely as a question of formal logic, for it is a claim that *this* body of factual knowledge is valid because of what it is; not any knowledge or even any like knowledge. We must therefore consider in outline what the sciences say about the world, how this alleged information has been acquired, and then evaluate it.

In the course of the first two inquiries we find that the most advanced scientific thought has its roots in what Lord Russell calls animal inference, or habit. If the tendency of animals to form habits had not run parallel with some sort of habit in their environment, they would not have survived. The utility of advanced scientific knowledge is a continuation of the process of adaptation through habit. Hume was content to leave the argument at this stage, because, after the eighteenth-century manner, he drew a sharp distinction between reason and animal habit, which the twentieth-century thinker sees no reason (or is not habituated) to draw. Lord Russell goes on to formulate minimum postulates which will validate existing scientific thought; or, to put the matter differently, what is the least assumption we can make about corresponding cosmic habit and mental habit to justify our continuing our habitual behaviour in future. He rejects phenomenalism because the physical process of radiation implies that between two observed events something can happen, which by hypothesis is not observed; in short, there cannot be continuity in the world if only observed events exist. He rejects pure empiricism because there must be some general principles, not just particular facts. To develop his system of postulates he uses the notion of 'structures'. The concept of structure may be logical in its origin, as he says; but it is certainly put to empirical use. A special but crucial example will illustrate what would justify such use. When we look at the full moon, is there literally, not metaphorically, the same kind of circular structure in the immediate datum of experience, in the astronomical object, in the intervening physical processes of radiation between the moon and our bodies, and in the physiological processes inside our bodies? If we can postulate such isomorphism (as Kohler calls it) it is easy to establish a theory of perceptual and scientific knowledge. But if we do, are not such isomorphic structures of the nature of Platonic forms, archetypes which make things what they are and also make them knowable? In recent writings Lord

Russell has fought shy of a realist view of universals, though never committing himself to nominalism. It looks as though he had returned to earlier views (as in "The Problems of Philosophy") or gone further still in realism.

Lord Russell puts forward his postulates as validating scientific knowledge. To anyone who objects that he has never believed them or even thought of them and does not see why he should, what is Lord Russell to reply ? Within the bounds of Hume's philosophy there is no reply except the kind which Hume himself supplied inadvertently. In the very process of dismissing causality as illusory, Hume used the notion of cause. The other reply would be a 'transcendental deduction of categories': Would Lord Russell desert Hume's camp, where he has dwelt so long, for Kant's ; and after all the hard things he has said about Kant ? Or is there another alternative ?

Some few minor complaints can be made about Lord Russell's discussion. He assumes that experience begins with a private ego-centric space, and he does not explain how, from that starting point, we can ever arrive at the public universal space required by physics. There is a chapter on the principle of individuation ; but the problem is shelved rather than solved.

After all allowances for blemishes have been made, this remains a very fine and characteristic piece of work ; written, too, with all the clarity, wit and gusto we have learned to expect.

A. D. Ritchie

AMERICAN USES OF GROWTH REGULATORS

Growth Regulators for Garden, Field and Orchard

By John W. Mitchell and Paul C. Marth. Pp. vii+129. (Chicago : University of Chicago Press ; London : Cambridge University Press, 1947.) 15*s*. net.

THIS book deals with the practical application of plant growth regulators in agriculture and in horticulture ; it has the initial merit that its authors have richly contributed to the studies of such applied science. In a very short section an introduction is effected to the various groups of available chemicals tabulated according to their chemical affinity ; for readers unfamiliar with recent progress this section could with advantage have been enlarged to include some consideration of the mechanism of the responses involved and some analysis of the reactions induced. But proceeding apace, the authors review the value of '2, 4, D' and 2, 4, 5, trichlorophenoxy acetic acid as herbicides, giving long lists of the resistant and susceptible plants, using only their common American names. But the discussion briefly deals with factors that influence the effectiveness of the chemicals ; temperature and soil conditions are not overlooked, nor are precautionary measures neglected. Reports of the use of other such compounds, at lower concentrations, to facilitate the vegetative propagation of plants, form a large section of the entire work, and the lengthy tables show many responsive plants and details of treatment. Botanical names and common names assist the reader here. Perhaps a critical discussion of the after-effects of certain substances, effective in root formation, but tending to delay bud development when used at rather too high concentrations, would have increased the value of this section. The use of esters of naphthalene acetic acid—intentionally—to inhibit the development of buds and 'sprouts' is well described, and here British readers will see that roses are so treated under American conditions of marketing the plants. The storage of potatoes may be prolonged without sprouting ; as there is always a chance that tubers meant for planting may be cooked, it is reassuring to read that no 'off' flavour nor any ill-effects were observed when such were used boiled or as chips ! Although young fruit trees have been retarded to some extent, without injury, it has not yet proved practical to delay the opening of fruit buds to avoid possible damage by frosts.

Paul C. Marth has been a pioneer in the use of growth substances to control the pre-harvest fall of fruit from the trees, and the review of the use of water sprays, of dust carriers, and of other methods of application, including the use of aeroplanes, is a valuable feature of this book, as are also the remarks concerning the importance of correct timing of the treatments. Naturally, the discussion of varietal responses centres around well-known American kinds and does not include much concerning British varieties.

A short chapter is included on the use of ethylene and other substances for accelerating the ripening process of bananas and citrus fruits. Similarly there is mention of the use of di-nitro-*ortho*-cresol and di-nitro-*o*-*cyclo*hexyl-phenol to thin out fruit blossoms, although these chemicals do not fall within the category of active growth substances as generally understood by British workers. The use of β-naphthoxy acetic acid and other compounds to produce seedless fruits is discussed.

The illustrations are good and helpful. There are lists of available American proprietary preparations given at the end of the chapters.

We have for long appreciated the work of the university presses concerned, and another example upholds the standard they set. M. A. H. Tincker

COLOUR

The Color of Life

By Arthur G. Abbott. Pp. xxi + 294 + 7 plates. (New York and London : McGraw-Hill Book Co., Inc., 1947.) 6 dollars.

COLOUR in life is inescapable, though some, being more observant, see more of it, especially the colour of natural things and natural phenomena, than others. Colour always has been and always will be associated with various arts and crafts in which the colouring agency such as dyestuff, as in the colouring of textiles, or the pigment, as in painting, is often man-made as well as man-assembled. Many of the great men of science since the time of Newton and his contemplation of the rainbow have been concerned with colour and have sought to explain just what colour is. Many are the known facts and theories about colour, for indeed the subject can be approached from many aspects. Thus the characterization of colour by mathematical symbols gives satisfaction to some, whereas others believe that the psychological effects of colour are the more worthy of study. Altogether there is to-day a greater and more widespread colour-consciousness, more appreciation of colour in Nature and in the broad activities of everyday life than ever before. It finds practical expression, for example, in the painting of factory walls and machines, in which colour now contributes to safety and eye comfort as well as to cleanliness and decoration in the ordinary sense.

The author, recognizing these things and clearly being fascinated by the subject, has sought to present its enormous sweep in a series of cameos in twenty chapters arranged in six groups under the following headings: 1, foundations of colour—light, matter and sight; 2, colours by Nature and how produced; 3, colours by man and how produced; 4, guides to use of colour—colour terms and names, harmony and discord in colour combinations; 5, colour for everyone—apparel and building; and 6, relation of colour to man's progress—special uses of colour.

In the result the substance of each chapter is a précis, or in some cases a partial abstract, of the reference books listed at the end of each chapter. At this point it is only fair to repeat some of the author's introductory words, namely: "This book is not intended to be a guide for any science, trade or profession, but a source of pleasure and profit for the average man, woman and child ... . to present a variety of facts, theories, experiences and observations about colour that will be interesting and useful. . . ."

There remains the question of accuracy. Are the factual statements which the author has made correct? On this I have to record that the chapter entitled "Paints" shows some confusion of thought, though comparatively little editing would have removed any cause for complaint. After all, it is not reasonable to be able to describe all the pigments, white and coloured, and the principles of paint manufacture, in nine not very closely printed pages. On the other hand, I was intrigued to read among a multitude of 'titbits' about a great variety of subjects that turkey flesh should have no purple tinge, as this marks an old bird—I shall examine my next turkey with added interest.

L. A. Jordan

TREATISE ON ZOOLOGY

Traité de zoologie

Anatomie, systématique, biologie. Publié sous la direction de Prof. Pierre-P. Grassé. Tome 11: Échinodermes, stomocordés, procordés. Par P. Brien, M. Caullery, L. Cuénot, A. Dalcq, C. Dawydoff, P. Drach, H. Harant, G. Waterlot. Pp. viii+1,078. (Paris: Masson et Cie., 1948.) 3,800 francs.

To older zoologists the title "Traité de zoologie" will recall the extensive work published by Prof. Edmond Perrier, the first volume of which appeared in 1893. It held its place on the bookshelf for many years, and even now some parts bear reference; but obviously in fifty years a vast amount of water has flowed under the bridge. The present work has a similar format and 'get up', but has a striking difference in that it has ninety-three collaborators from France, Belgium, Switzerland, Algiers, Egypt and Morocco, united under the direction of Pierre-P. Grassé, professor at the Sorbonne. This new treatise is planned to extend to seventeen volumes, each of which will consist of about 1,000–1,200 pages and will be fully illustrated.

The publication of such a large work has dangers not encountered in issuing a single large volume, or a small number of volumes. It may spread over such a long period that the first volumes are quite out of date before the last ones appear, so that it does not form a usable whole; or it may suffer the fate of Lankester's "Treatise", Délage et Hérouard, or Kükenthal und Krumbach, which were never completed. It is to be hoped that the present commendable work will avoid these dangers, and the fact that a large number of authors are collaborating may help. Four more volumes are scheduled to appear in 1949, and at least three in 1950; and if this rate is maintained the work should be completed in little more than four years, a not unreasonable time. The large number of contributors should also make it possible for each section to be up to date and authoritative, for it is obviously impossible for one or even a small group of authors to cover adequately the vast field of modern zoology.

The volume at present under review, while it is number 11 in the series, is actually the first to appear, and so may be taken as a sample of those to follow. It contains 1,078 pages with 993 figures, 11 of which are in half-tone, 11 reinforced by colour, and the remainder in line block; they are deserving of high praise. The volume deals with the systematics, anatomy and biology of the Echinodermata, Stomochorda (Hemichordata) and Prochorda (Tunicata and Cephalochordata). Each section is provided with its own bibliography, which varies in extent according to the availability of recent bibliographies. The principal contributors are Profs. L. Cuénot (Nancy), C. Dawydoff (Paris), P. Brien (Brussels) and P. Drach (Sorbonne). The group Stomochorda is set up because the pharyngeal diverticulum lies near the mouth, and it is held that this is a structure *sui generis* and is not strictly homologous with the notochord of the true chordate. The structure itself is referred to as a stomochord (stomocord) to emphasize this distinction. The recent researches of O. M. B. Bulman and Kozlowski, taken fully into account, show that the Graptolites are more closely allied to the Pterobranchia than they are to the groups with which they have been associated previously, the Sertularian Hydrozoa or the Bryozoa, and consequently they have been included as a class of the Stomochorda. Cuénot has a discussion (pp. 359–361) of the relationship of the dipleurula of the Echinoderms to the tornaria of the Enteropneusts, and of the basic trimerism of the former phylum as indicated by the development of the cœlom. This, read in conjunction with the fuller discussion by Dawydoff of the Stomochorda and their affinities (pp. 511–532), shows clearly that both authors recognize an ancestral relationship between the Echinodermata and the Stomochorda, and, of course, the latter are clearly related to the Prochordata. Thus the three groups are logically included in the same volume.

On the whole the book is excellently printed and illustrated, and the paper is very good. A detailed index is furnished and a very full table of contents which is placed right at the end of the volume. It is a pity that a number of slips have been allowed to pass uncorrected, for example: p. 297, deutoplosme for deutoplasme; p. 362, Mac Millan for Macmillan; p. 488, McIntosch for McIntosh; p. 452, Bulloc for Bullock; p. 947, fig. 407, *e* in the diagram is *Fe* in the legend; and p. 494, fig. 408, *v s* in the diagram is *vis* in the legend, etc. Apart from these, the authors, editor and publishers are to be congratulated on initiating a series of volumes that should prove most useful to all zoologists, and we wish their venture every success.

C. H. O'Donoghue

Medicine and Science in Postage Stamps

By W. J. Bishop and N. M. Matheson. Pp. 82 (33 plates). (London: Harvey and Blythe, Ltd.; H. K. Lewis and Co., Ltd., 1948.) 7*s*. 6*d*. net.

WHILE the emphasis in this little book is on medical interest, the authors also refer briefly to scientific workers in the widest sense who have been commemorated by special stamps; among whom are Tycho Brahe, Ampère, Descartes, Linnæus, Mendel, Berthelot, Edison, Marconi and the Curies. The book contains a 16-page account of the reasons for the issue of such stamps; there are short sections on portrait stamps, Red Cross stamps, various tuberculosis stamps, illustrations of hospitals and other medical institutions, the use of medical symbols and apparatus, and other stamps of medical interest. There follow thirty-three plates giving black-and-white reproductions of 148 such stamps from the authors' collections. The book ends with 23 pages of biographical notes, arranged alphabetically, relating to the portrait stamps mentioned. There is also a bibliography.

In addition to stamp collectors among the medical and related professions to whom the book is specifically addressed, it may well arouse interest in this instructive hobby among others interested in scientific developments.

Meson Theory of Nuclear Forces

By Wolfgang Pauli. Second edition. Pp. vii+69. (New York and London: Interscience Publishers, Inc., 1948.) 12*s*.

THIS second edition differs from the first (reviewed in *Nature*, **160**, 418; 1947) only in a few short sections, where instead of older experiments some more recent ones are discussed (concerning the angular distribution of proton-neutron scattering, p. 56, and the consequences of strong coupling theory, p. 64). The most interesting feature of the new edition of the little book is its preface, where the author refers to new discoveries incompatible with the present theory, such as the existence of different kinds of mesons and the absence of negative meson capture by the lighter nuclei. He hopes that artificial production of mesons recently achieved in the United States will bring forth a great change of the whole situation in the near future.

Isomerism and Isomerization of Organic Compounds

By Ernst David Bergmann. (Polytechnic Institute of Brooklyn: Lectures on Progress in Chemistry.) Pp. xi+138. (New York and London: Interscience Publishers, Inc., 1948.) 21*s*.

THIS little book presents the material of six lectures delivered by the author during 1945–46, and deals only with those aspects of its subject which have most interested him. This limitation is made clear in the preface, and the would-be reader should not be misled by the wide title of the book into expecting even an outline of the whole field. The book is a very personal approach to the subject, and presents an individual outlook which will probably not commend itself to the majority of qualified readers; thus, it will surprise many to find, in a chapter entitled "Mechanism of Substitution Reactions; Racemization and Walden Inversion", only one reference, and that purely experimental, to the work of Ingold and his school. Some of the theoretical interpretations are also highly individual and will be regarded by many as very questionable; for example, the surprising statement (p. 119) that, in the rearrangement of phenyl allyl ether, "a van der Waals' link is established between the unsaturated γ-carbon atom and the ortho position". Although, as the author hopes in his preface, the book may provide "food for thought" for the critical reader, it is certainly not suitable for students, and from this point of view its high price is to be welcomed.

H. N. RYDON

The Faith of Reason

The Idea of Progress in the French Enlightenment. By Charles Frankel. Pp. x+165. (New York: King's Crown Press; London: Oxford University Press, 1948.) 16*s*. net.

FOR the philosophers of the French *Enlightenment* theirs were grand days. They were grand because the errors of history and of circumstance were at long last understood; reason would put everything right. Thus the enthronement of scientific method; the fields were white to harvest with the fruits of Cartesianism, all ready for the garnering; and this not necessarily against the winter, for such seasons would be mild in future, their edges rounded off by a generous humanity, which quality, by the way, was thought to be identical with reason itself.

The brilliance of these savants is beyond question; what seems odd to us now is their limited imagination, due in the main to a system of metaphysics telling them exactly what they were about to find, and keeping them in fetters while looking for it. Nevertheless, we are assuredly their debtors in the sphere of moral progress.

Much of the temper of the *philosophes* is of concern to society to-day, especially when the uses of science are subject to attack, and there is much talk of 'irresponsibility'. Dr. Charles Frankel, aided by the King's Crown Press, has performed a valuable service in producing this monograph. Between its covers can be found a critical, but not pedantic, account of an age at the moment somewhat neglected in the history of thought.

F. IAN G. RAWLINS

Shetland Sanctuary

Birds on the Isle of Noss. By Richard Perry. Pp. 300+32 plates. (London: Faber and Faber, Ltd., 1948.) 25*s*. net.

THE island of Noss on the eastern side of the Shetland group is a well-known resort of seabirds, the great cliff known as the Noup of Noss that faces the North Sea being a breeding place of countless kittiwakes, guillemots and razorbills, plus many gannets. In addition, great skuas and Arctic skuas nest on the grassy expanse of the island. These are but some of the bird attractions of Noss. The island well deserves the title of "Shetland Sanctuary" under which Mr. Perry describes it in his latest book.

In this book the author tells us of his five months work on Noss, during which he made his headquarters in the old farm-house, now, alas, falling into disrepair, while his wife and child found a less arduous habitation on the nearby island of Bressay. To appreciate the author's results one must read his careful studies of the great skua, the Arctic skua and the gannet, with sidelights on many other birds. In the space of a brief review it is difficult to give much idea of them, and we must refer the reader to the book itself, which in our opinion is the best Mr. Perry has written.

F. P.

COCOA DISEASE IN THE GOLD COAST

FOR some years past, increasing uneasiness has been felt about the future of cocoa in West Africa and particularly in the Gold Coast. Trees began to die in ever-increasing numbers, and at first the trouble was attributed to 'die back' and physiological troubles, due to the excessive removal of high forest which occurred during the rapid opening up of the country for new plantations. This it was believed let in the dry 'harmattan' winds from the Sahara, causing a less favourable environment for the cacao tree. As a remedial measure the establishment of shelter belts of high forest was recommended, and in due course they came into being; but the trouble still continued to spread and remained an unsolved puzzle until one of the scientific officers, stationed on the newly opened Cacao Research Station, established that the cause is a virus disease. The research station is situated at Tafo in the middle of one of the badly infected areas of the Eastern Province, and was opened about ten years ago. It has done valuable work in establishing that several types of virus are responsible, that infection is conveyed by particular species of mealy bugs, and that certain species of indigenous forest trees can serve as alternative hosts.

The Station has also devoted much attention to methods of control and has come to the conclusion that the basic method for dealing with a disease of this type is the removal of sources of infection. This means cutting out not only trees that are obviously beyond hope of recovery, but also trees that show symptoms of the disease but are still bearing some fruit. Most of the cocoa farmers are poorly educated men, with only two or three acres apiece, and it naturally went against the grain to ask them to destroy trees that were apparently still capable of producing a few pods, especially at the present time when prices are exceptionally high. Attempts to apply this 'cutting out' cure have been unpopular and have been strongly resisted by the growers. Unfortunately also, local politics were dragged in, so that serious disturbances took place in March 1948, with the result that the legal powers to compel cutting out, which already exist, have not been enforced. For nine months or more the disease has to all intents and purposes been allowed to spread unchecked, for the cutting out campaign has been suspended.

As a consequence of these events, a special commission was sent out by the Colonial Office in May 1948 to report on the disturbances, and acting on one of its recommendations, a panel of three plant pathologists of international repute, drawn from countries not commercially interested in cocoa growing, was selected to study the disease and report on its control or eradication. These men were appointed to the commission after consulting the United Nations Food and Agriculture Organisation, and their report has now been issued*, giving an entirely independent and up-to-date account of the cocoa position in the Gold Coast. In the first place, they entirely endorse the conclusion reached some years ago by the West African Cacao Research Station at Tafo, that cutting out is, at present, the only practical control measure. They point out the magnitude of the problem involved, as this means cutting out at least fifty million diseased cacao trees and several million wild host trees. Nobody knows how many cacao trees there are in the Gold Coast, but the figure may be of the order of 400 million; under these proposals, therefore, it seems probable that one-eighth of the existing cacao trees would have to go. So far, under the existing voluntary cutting-out scheme, not more than three million trees have been removed.

The urgency of the problem is emphasized since the disease is spreading at the rate of fifteen million trees a year, and has recently made great headway, because control measures have practically ceased since the March riots. The Eastern Province was the first area affected, and large blocks of cacao have been killed in what was formerly the most productive cocoa belt. The disease has spread to Ashanti, where former isolated outbreaks have extended to an alarming degree. The Western Province is still more or less in the period of sporadic outbreaks, but there is every prospect of its following the other two provinces unless adequate measures are taken. The Commission points out that far more vigorous action will have to be taken if there is to be any hope of saving the industry. Not only will the staff of the Agricultural Department need to be greatly strengthened, but means will have to be taken to bring home to all sections of the public the urgency of the matter and the definite threat to the whole industry, on which depends ultimately the prosperity of the entire country; for the Gold Coast relies to a frightening extent on the revenue obtained from its cocoa crop.

The Commission recommends, therefore, that the first and most important task is to educate all classes of the population to the seriousness of the position, and to secure their support for the 'cutting out' campaign. Until public opinion has been educated up to this point, it will not be easy to carry out the drastic campaign envisaged. It must be remembered that cocoa in the Gold Coast is produced by many thousands of peasants farming two or three acres each, or working land belonging to absentee landlords. The majority of these men are illiterate, and the difficulty will be to bring home to them the facts of the case. Something can be done by an extension of the radio system to the villages and markets; but the best way is probably personal conversation with a representative of the Government. Even a greatly enlarged staff in the Agricultural Department could only contact a small proportion, and it will be necessary for the campaign of enlightenment to be carried on by members of all Government departments, native authorities and chiefs' councils, and the Press.

It is obvious that, for the cutting-out programme to be effective, it must not only be vigorous but also thorough. It will be useless to treat most of the fields in an area and leave two or three untreated plots because the owners refuse to co-operate. These plots will be the cause of rapid re-infection of the neighbouring fields. Eventually it is hoped that public opinion will insist that all must play their part for the general good. It is obvious, however, that time will be needed to reach such a desirable state of affairs, and the need for a publicity campaign emphasizing the vital stakes at issue is all the more urgent.

---

* Colonial Office: Report of the Commission of Enquiry into the Swollen Shoot Disease of Cacao in the Gold Coast. (Colonial No. 236.) Pp. 10. (London: H.M. Stationery Office, 1948.) 3*d.* net.

While endorsing the control methods of the Cacao Research Station, the Commission is inclined to think that the method of cutting out may need to be even more stringent if the disease is to be eradicated permanently from a particular area. It is pointed out that it is not sufficient merely to cut out trees showing signs of the disease; neighbouring trees that are in contact are also probably diseased, although they may not show symptoms until a later stage. The contact trees, therefore, will also have to go. It will be difficult to persuade the peasant farmer to cut out an apparently healthy tree by assuring him that it is the only way that his crop can be saved in the future. Since only a vigorous and thorough removal of infection sources can be expected to achieve a reasonable degree of success, the Commission thinks it advisable that the limited staff at present available should concentrate its efforts in areas of lesser infection, particularly Ashanti and the Western Province.

It may be that eventually the so-called 'raging belt' area of the Eastern Province, where the cacao fields have been practically wiped out, may prove to be the best place to resuscitate the industry, and at the same time replace the old methods by something more in keeping with the present time. In this area large areas of cacao have ceased to exist—only here or there a few trees struggle on. With the co-operation of the chiefs and their peoples, it might be possible to start new plantations on modern lines. This would entail the planting of cacao in large compact units instead of thousands of small scattered plots as at present. The area selected would have all existing cacao and wild host trees completely removed, and be left fallow for two or three years before replanting. The new area would be planted in rows at the most desirable distance apart, and this would enable spraying machinery to be worked if at any time action was needed in the future. At present, Gold Coast cacao is planted in a most haphazard way, and it is impossible to get into the crop to spray or prune.

A plantation of the type envisaged would have a relatively small periphery for its acreage, and border control of invasion from outside should be comparatively easy. There would be difficulties over land tenure and other customs, and these would have to be the subject of careful consideration and of goodwill on the part of the village authorities.

The fact remains, however, that one cannot envisage the Gold Coast succeeding in reviving its cocoa industry by relying on the old happy-go-lucky methods. There would be no guarantee that a crisis similar to the present one might not again arise. It is unimaginable that a disease of this nature could have got out of hand in this way if the crop had been properly cultivated and organised on a more rational basis. The present calamity that has befallen the Gold Coast cocoa crop may in the end, therefore, prove a blessing in disguise. If the growers are wise, they will take the opportunity of putting their industry on a sound basis. They will learn to treat their cacao as an orchard crop and not as a bit of jungle.

The establishment of plantations on the lines mentioned will enable modern up-to-date methods to be employed and better material planted. The research workers must have time to make their investigations; but already there are signs that higher-yielding, disease-resistant varieties may be forthcoming, and better methods of cultivation, fertilizing and disease control become available.

The Commission points out with reason that inadequate attention to the situation up to the present has allowed the disease to gain such headway that effective and immediate action is needed. One of the problems that as yet remains unsolved is the extent to which wild trees and plants are alternative hosts. It is known that the silk cotton tree, the cola and three or four species of Sterculiaceæ are carriers of the virus; but there may be others, and the search is still being continued. The destruction of some of these trees will present a big problem, for many of them are giants of 200 ft., with buttressed roots rising to 30 ft. in height. The possibility of destroying them by chemical means is being considered, but even so the task of killing several millions of such trees will be a stupendous one. The replanting of lightly affected areas will also prove difficult. It seems that more preliminary work is needed to ascertain the margin of time when it can be deemed safe to replant in lightly affected areas, from which a few diseased trees have been removed. Young cacao trees apparently show few signs of disease for the first three or four years, but after that, when their canopies become contiguous, they may become re-infected unless a complete sweep has been made of all possible sources of mealy bug infection.

The best hope for the future lies in continued research on the lines indicated in the report, coupled with a determination to re-establish the industry on rational lines; and for the present to attempt to alleviate the existing crisis by intensifying the 'cutting-out' campaign. GEOFFREY EVANS

RECENT ADVANCES IN THE CHEMISTRY OF HYDROCARBONS*

By Dr. S. F. BIRCH
Research Station, Anglo-Iranian Oil Co., Ltd.

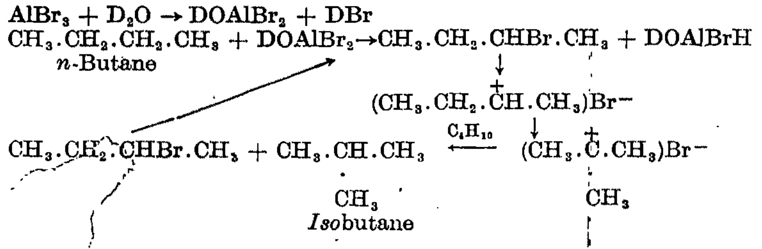
THE demand for highly branched *iso*paraffins for use in higher-performance aviation fuels has stimulated research during the last ten to fifteen years into methods for producing such hydrocarbons in large quantities from available raw materials. Of the processes resulting from this work those based on isomerization and on alkylation are of outstanding importance.

In the isomerization process the molecular structures of the paraffins, particularly of the normal members which occur naturally in petroleum, are re-arranged to the required branched structures. Such re-arrangement is a reversible first-order reaction in which at low to moderate temperatures the equilibrium favours branched structures, but with increasing temperature the equilibrium shifts towards straight-chain structures. In the absence of catalysts the attainment of equilibrium is extremely slow even up to temperatures at which the hydrocarbons are thermally unstable, while in the presence of catalysts side-reactions become more marked as the temperature increases.

The most satisfactory catalysts for paraffin isomerization are the aluminium halides promoted by certain compounds such as hydrogen halides, alkyl halides, oxygen, water and olefins. These combinations are extremely active under relatively low-temperature conditions, apparently acting heterogeneously at liquid – liquid or liquid – solid interfaces. Since a promoter is necessary, the aluminium halide itself does not appear to be the catalyst. It has been suggested that acids of the structure $HAlX_4$ are the true catalysts, but this takes no account of the findings of Wackher and Pines that, in the isomerization of butane, traces of olefins, water or oxygen are necessary in addition to the hydrogen halide. Also, a recent study by Fontana and Herold[1] has shown that the vapour pressure of hydrogen bromide in contact with aluminium bromide is not abnormal, as it might be expected to be if such a complex were formed. The most plausible mechanism is that put forward by Wackher and Pines[2] on the basis of their work with partially hydrolysed aluminium halides. These workers found that the most effective catalyst was obtained by adding one molecule of water for each molecule of halide present, and, by using deuterium oxide in place of water, they were able to compare the rate of deuterium – hydrogen exchange between $DOAlBr_2$ and butane while the hydrocarbon was isomerized. The results of this investigation indicated that it is the bromine of the partially hydrolysed halide that takes part in the reaction, and accordingly the following mechanism has been put forward :

---

* Substance of a series of lectures delivered at the Royal Institution, beginning November 16.



$$\mathrm{AlBr_3 + D_2O \rightarrow DOAlBr_2 + DBr}$$
$$\underset{n\text{-Butane}}{\mathrm{CH_3.CH_2.CH_2.CH_3}} + \mathrm{DOAlBr_2 \rightarrow CH_3.CH_2.CHBr.CH_3 + DOAlBrH}$$
$$\downarrow$$
$$\mathrm{(CH_3.CH_2.\overset{+}{C}H.CH_3)Br^-}$$
$$\downarrow$$
$$\mathrm{CH_3.CH_2.CHBr.CH_3} + \underset{Isobutane}{\mathrm{CH_3.\underset{CH_3}{CH}.CH_3}} \xleftarrow{\mathrm{C_4H_{10}}} \mathrm{(CH_3.\underset{CH_3}{\overset{+}{C}}.CH_3)Br^-}$$

In alkylation, highly branched *iso*paraffin molecules are built up by the combination of low molecular weight olefins and paraffins such as are normally available from refinery operations. Using a complex catalyst consisting of boron trifluoride activated by nickel powder and hydrogen fluoride or water, Ipatieff and Grosse[3] were the first to show that such a reaction is possible, although Parks and Huff[4] seem to have concluded some time previously from thermodynamical considerations that this type of reaction is feasible. It was next reported by Frey and Hepp[5] that such alkylation could also be effected non-catalytically under rather drastic conditions of temperature and pressure, 500° C. and 300 atmospheres ; thermal alkylation was, however, possible only with lower olefins and paraffins, except for methane and ethane, which have so far resisted all attempts, catalysed or uncatalysed, to react in this way.

Thermal alkylation has been employed technically to produce 2.2-dimethylbutane (*neo*hexane) from *iso*butane and ethylene on a comparatively large scale, but the greatest developments in alkylation processes have followed the use of the practical catalysts, aluminium chloride (activated with hydrogen chloride), sulphuric acid and hydrogen fluoride. Aluminium chloride possesses the advantage over sulphuric acid and hydrogen fluoride that it enables normal- as well as *iso*paraffins to be alkylated ; normal paraffins are presumably first isomerized to the *iso* form. Technically, aluminium chloride has been employed to produce 2.3-dimethylbutane ('di*iso*propyl') from *iso*butane and ethylene, a reaction that could not be brought about by the other two catalysts. This formation of di*iso*propyl rather than *neo*hexane as in thermal alkylation has been explained by Schmerling[6] on the basis of a chain mechanism involving the preliminary formation of an alkyl halide from the olefin and hydrogen chloride, leading to a *neo*hexyl structure which then isomerizes to the di*iso*propyl structure in the presence of aluminium chloride.

The most generally employed alkylation catalyst is sulphuric acid, hydrogen fluoride being used to a less extent. Both compounds are completely ineffective for the alkylation of normal paraffins, and their use is restricted to *iso*paraffins. The alkylation of *iso*butane with butenes has been the most important technical alkylation, although propene and pentenes have also been used. Schmerling has suggested a mechanism for sulphuric acid alkylation similar to that for reactions catalysed by aluminium chloride ; but this seems less likely, and the mechanism must still be regarded as obscure. The products from sulphuric acid alkylations consist of a complex mixture of *iso*paraffins boiling over a wide range of temperature, and under favourable reaction conditions the major part is of the desired molecular weight. By the end of the War, some 5½ million tons a year of *iso*paraffins were being produced by alkylation, and the process is still being operated on a considerable scale.

While isomerization and alkylation processes enabled most of the high-performance aviation fuels to be produced in vast quantities, one material, 2.2.3-trimethylbutane (triptane), could not be made in the required amounts by these methods, and it was necessary to devise alternative processes. Two solutions to this problem were eventually forthcoming. Thus Lovell and Miller[7], on the basis of an observation in 1882 by Eltekoff[8] that 2.3.3-trimethylbutene-1 was a by-product from the treatment of trimethylethylene with methyl iodide and litharge, investigated the interaction of trimethylethylene with methyl chloride in the presence of lime, and obtained a product containing appreciable quantities of 2.3-dimethylbutene and 2.2.3-trimethylbutene (triptene). By recycling the dimethyl compound, further methylation took place, and an enhanced yield of triptene was available. Hydrogenation of the triptene gave the desired triptane. A second route to the same hydrocarbon was discovered by Ipatieff and Haensel[9], who found that, in the presence of metals such as cobalt and nickel and under hydrogen pressure, demethylation of higher *iso*paraffins occurs to yield the next lower homologue and methane. By applying this reaction to 2.2.3-trimethylpentane, one of the *iso*octanes formed by the hydrogenation of butene–*iso*butene codimer, triptane was obtained. Owing to difficulties encountered in separation of the triptane from the original *iso*octane and accompanying *iso*heptanes, the method of Ipatieff and Haensel was less successful than that of Lovell and Miller.

Contemporaneously with the need for *iso*paraffins for aviation fuel, the War also intensified the demand for large quantities of butadiene and styrene for synthetic rubber production. These two compounds were obtained similarly by the catalytic dehydrogenation of butane and ethylbenzene respectively. Considerable difficulties had to be surmounted to obtain the desired products, for paraffin dehydrogenation is a strongly endothermic, reversible reaction in which comparatively high temperatures (400–700° C.) are necessary to favour dehydrogenation. At these temperatures cracking and, when the paraffins contain more than five carbon atoms in the chain, cyclization, may be marked.

The dehydrogenation of butane on a technical scale[10] was carried out as a two-stage process, the butane being first converted to butenes over a chromium oxide–alumina catalyst at 450 – 490° C., the light gases and butane being separated, and the purified butenes then being further dehydrogenated to butadiene at a somewhat higher temperature in the presence of ten to twenty volumes of high-temperature steam. The addition of steam had the triple advantages of reducing cracking, providing heat for the reaction and removing carbonaceous deposits from the catalyst. Butadiene was separated from butenes and butanes by azeotropic distillation.

Ethylbenzene has been dehydrogenated to styrene under somewhat similar conditions[11] using a chromium oxide – alumina catalyst. The separation of styrene (b.p. 145° C.) from unchanged ethylbenzene (b.p. 136° C.) presented a problem which was complicated by the fact that styrene polymerizes readily at its boiling point under atmospheric pressure. The difficulty was eventually overcome by adding a small quantity of sulphur as a polymerization inhibitor to the feed to the still, working at reduced pressure and dividing the necessary 70-plate fractionating column into two sections.

As already mentioned, under dehydrogenation conditions, hexane and the higher paraffins tend to undergo cyclization to aromatic hydrocarbons. This appears first to have been observed by Moldavski[12], but has also been extensively studied by a number of workers in Great Britain[13] and in the United States. A molybdenum oxide – alumina catalyst is better for cyclizations than a chromium oxide – alumina one.

An interesting offshoot of the work on the production of butadiene by dehydrogenation of butane was the preparation of thiophenes from sulphur and lower paraffins containing four or more carbon atoms in a chain. Thiophenes are now being produced by this means on a considerable scale in the United States[14], and a new field of chemistry is opening up.

It is not possible to deal adequately here with all the new advances in hydrocarbon chemistry, but, in addition to those indicated above, there may be mentioned sulphochlorination and sulphoxidation, telomerization, the 'Oxo' synthesis (see below) and the new acetylene chemistry developed in Germany.

The introduction of a sulphonyl chloride group into paraffins by treatment with chlorine and sulphur dioxide in presence of actinic light was discovered by Reed[15] in the United States. However, the greatest development of the process has probably been in Germany during the War when, on a considerable scale, C_{14}—C_{16} normal paraffins from the Fischer–Tropsch reaction were used to produce alkanesulphonate-type detergents[16]. In a modification of this reaction a paraffin was treated with oxygen and sulphur dioxide in the presence of acetic anhydride during irradiation with ultra-violet light; a peranhydride of acetic and alkanesulphonic acid resulted, and this decomposed in the presence of more paraffin, sulphur dioxide, oxygen and water to yield the sulphonic acid in the ratio of 7–9 molecules for each molecule of peranhydride decomposed[17].

'Telomerization' is the term employed to denote an olefin reaction that has been investigated extensively in the du Pont Laboratories and elsewhere in recent years. Kharasch had shown that, in the presence of peroxides or when irradiated by ultra-violet light, olefins would add on a molecule of a halogenated methane, a halogen going to one end of the double bond, the rest of the methane molecule to the other[17]. When this is carried out under polymerization conditions, the product contains more than one olefin molecule per molecule of non-olefin[18]; the reaction is then a 'telomerization', the non-olefinic adduct a 'telogen' and the reaction product a 'telomer'. Other types of compound such as chloralkane carboxylic acids and their esters, aldehydes, hydrogen halides, etc., also function as telogens. The reaction is of considerable interest in providing a means for building up long-chain compounds with reactive terminal groups.

From a technical aspect one of the most important reactions discovered in recent years is the Roelen reaction or 'Oxo' synthesis, which involves the simultaneous addition of hydrogen and carbon monoxide to an ethylenic bond under certain conditions of temperature and pressure in the presence of cobalt catalysts[19]. Simple olefins yield a mixture of the two isomeric aldehydes to be expected from the addition of the formyl group to either end of the double bond; but structural variations in the olefin influence the proportions of the aldehydes formed, and, in the extreme case when a tertiary carbon atom is at one end of the double bond, the formyl group is added only to the other end. If tertiary carbon atoms occupy both ends of an ethylenic linkage, reaction may still occur if, under the experimental conditions, isomerization to a suitable configuration can take place first[20].

Of outstanding interest theoretically as well as technically is the new field of chemistry that has been opened up by Reppe's work on acetylene reactions[21]. From the many reactions examined, two are of particular interest, namely, the production of acrylic acid from acetylene, carbon monoxide and water in the presence of nickel carbonyl, and of butine-1.4-diol from acetylene and formaldehyde in the presence of copper acetylide. The former reaction opens a new route to polymer-forming materials, the latter to a wide range of organic intermediates including butadiene and tetrahydrofurane.

The polymerization of acetylene to *cyclo*octatetraene in the presence of certain nickel catalysts[22] opens up a new field for investigation by providing a convenient source of this extremely interesting hydrocarbon.

OBITUARIES

Prof. John Percival

JOHN PERCIVAL was born at Carperby in Wensleydale on April 3, 1863, and died on January 26, 1949, being survived by his widow and son.

He was educated locally, but later proceeded to Cambridge and graduated from St. John's College in 1888 with honours in Parts I and II of the Natural Science Tripos. Even during his boyhood he was an ardent field naturalist and, while still a student, published a "Flora of Wensleydale" which listed 653 species and varieties, of which all but ten had been seen by himself.

In 1891 he was appointed junior demonstrator in the Chemical Laboratories of the University of Cambridge, and joined that small band of educational pioneers, led by A. D. Hall, who carried agricultural science into the rural areas. During three years he gave numerous courses of "Cambridge University Local Lectures" on botany and chemistry in relation to agriculture, and it was this intimate contact with Surrey and Suffolk farmers and experience in wedding science to agricultural practice that laid the pattern of his life-work.

When the Wye Agricultural College was founded in 1894, Percival was appointed professor of botany and concentrated his attention mainly on hops and cereals. He published several papers on the history, varietal development and diseases of the hop plant which laid the foundations on which E. S. Salmon was to build so brilliantly later. He assembled a living museum of cereals, described in his pamphlet "The Chief Species, Races, and Varieties of European Cereals", this being his first essay in a field which was to become the dominant passion of his life. In 1902 he published a short paper in which the causal relation of *Stereum purpureum* to silver leaf disease was first demonstrated, a problem later developed by F. T. Brooks. In his teaching at Wye, Percival felt acutely the lack of any text-book of his subject, and met this need by his "Agricultural Botany"; in the course of thirty-eight years this ran into eight editions and was translated into many languages. It is easy nowadays to criticize this volume; but, in its day, it was a pioneering effort in a new field, a field itself almost created by Percival, and the several editions have largely shaped the development of the subject in university and college teaching.

In 1902, Percival was appointed director of the Agricultural Department in what was then the University College, Reading, and in 1907 became professor of agriculture. For ten years he had to cover the whole field of agriculture, and his publications ranged over such diverse topics as weeds, mountain pines, manures and manuring, and the "Soils of Dorset"; in 1907 he was one of the presidents of the Second National Conference of the Poultry Industry. In 1910 he published his researches on "Potato 'Wart' Disease", which gave the disease and the pathogen their modern names and laid the foundations of our knowledge of this problem. During this period he was also assembling and making an intensive study of the world's wheats, and building up in Reading a centre of agricultural education and research. In 1910 he published his "Agricultural Bacteriology", again a pioneering effort in a new and rapidly developing field which the book largely patterned.

In 1912 a chair of agricultural botany was established in the College and Percival became the first professor, holding this appointment until his retirement in 1932: in 1926 the College had become the University of Reading. Percival was at last able to devote all his energies to his wheats. Earlier he had founded an Agricultural Botanic Garden containing a living museum of wheats, and he developed this until it comprised many thousands of named species, varieties and races of *Aegilops* and *Triticum* collected from all over the world. In 1921 this work came to splendid fruition in his monumental treatise, "The Wheat Plant", which at once gave him recognition as the foremost world authority: among his correspondence are letters from Vavilov and other specialists containing glowing tributes to "this classic work".

During the next ten years Percival devoted his attention to the cytological analysis of *Aegilops* × *Triticum* hybrids, on which he published several papers, and began the preparation of his book on "Wheat in Great Britain" which was published in 1934, and appeared in a second edition a few months before his death. During his last years he was actively engaged in research on seed germination and seedling growth. In his old Department at Reading there remain his fine herbarium of British plants, his remarkable collection of seeds, a complete set of dried specimens of his wheats with his annotations, and the living museum of wheats and the Agricultural Botanic Garden which he founded.

John Percival was no ordinary man. His force of character, tireless enthusiasm and immense physical and mental energies enabled him to achieve a vast amount of enduring work. He was an accomplished linguist, a musician and artist of merit, an expert photographer, a scholar, and a lover of books, of which he possessed an astonishingly wide and intimate knowledge. He was an inspired teacher with an encyclopædic knowledge of agriculture and botany on which he could draw at will. He was equally at home with both student and farmer; but there was always about him a certain brusqueness and an aloofness from the common world which made him impatient of trivialities; nor did he suffer fools gladly. He was a splendid field naturalist, loving wild things and wild and lonely places, and it was this passion that, in his earlier years, took him to remote Scandinavia to dwell for months among the Lapps, and later compelled him to the Alps and the Pyrenees, to the Welsh mountains, and ever and again to his own beloved Yorkshire dales.

John Percival was an eminent scientist who, perhaps, received more recognition in other countries than in his own, and in his passing, agricultural science has lost a memorable figure.

WILLIAM B. BRIERLEY

Dr. M. C. Rayner

BY the sudden death of Dr. M. C. Rayner, on December 17, British mycology has sustained a serious loss. Up to the last moment she had been pursuing her researches into the mycorrhizal habit in plants, and, in fact, died only a few hours after visiting her experimental plots at Wareham Heath in Dorset. Relatively early in her career, Dr. Rayner had established herself as unquestionably the leading British authority on the subject of mycotrophy in plants—a position which she afterwards consolidated both by the volume of her own research, and by the breadth of her interests in her chosen field of work.

Dr. Rayner's interest in the mycorrhizal habit, and her scientific collaboration with Prof. W. Neilson Jones, to whom she was married in 1912, both started in 1910 with an inquiry into the ecology of *Calluna vulgaris* on the Wiltshire and Berkshire Downs. This investigation led a few years later to the publication of a now classical paper for which she was awarded the degree of D.Sc. by the University of London, on "Obligate Symbiosis in *Calluna vulgaris*". In this paper she established in great detail the nature and extent of the association between *C. vulgaris* and its fungus endophyte, *Phoma radicis callunæ*. Numerous other papers on the endophytic mycorrhiza of heath plants followed, and in 1927 she published her monograph on "Mycorrhiza", as a *New Phytologist* reprint; more than twenty years later, this monograph is still an invaluable work of reference, as well as a pleasure to read.

As a result of a discussion in Bagley Wood, Oxford, on the occasion of the British Association meeting in 1926, Dr. Rayner started work on the other large group of mycorrhizal fungi, the ectophyte associates of forest tree roots. This led both to some most interesting fundamental work on the nature of ectophytic mycorrhiza, and to the solution of an important practical problem—the establishment of young conifers on the Wareham Heath area of Dorset, a difficulty that had for some time vexed the Forestry Commission. Later the Commission provided Dr. Rayner with a research nursery and a scientific helper to assist her investigations at Wareham and elsewhere. Dr. Rayner's series of papers on these tree investigations, together with other contributions by herself and Prof. Neilson Jones, were reprinted in 1944 by Messrs. Faber and Faber in a single volume under the title "Problems in Tree Nutrition"—an indication of the wide interest aroused by this work. In recent reports, Dr. Rayner has stressed the importance not only of the compost but also of the system of cultivation used in conjunction with it, for the promotion of maximum fungal activity and for the maintenance of soil fertility in the forest nurseries. Dr. Rayner's precise interpretation of her results on the Wareham Heath plots is still a subject for controversy and further experiment; none would deny, however, that by her striking demonstration of the value of organic composts for the establishment of coniferous seedlings she has been an outstanding benefactor to forestry.

At times, Dr. Rayner was wont to deplore the controversy, not infrequently bitter, that has always ranged around the subject of mycorrhiza, and in which, during her life, she was well to the forefront. Partly as a result of her own work, however, the benefit to the host of the ectophytic mycorrhizal association is now established almost beyond question, even though its mechanism still requires further elucidation. The benefit derived from the endophytic mycorrhizal habit, by heath plants, orchids and others, on which Dr. Rayner insisted so strenuously, has always been harder to prove; for a long time, the crucial experiment always seemed to be just beyond the grasp of investigators, but recent work suggests that the fungus endophyte may bring about the successful establishment of its seedling host by supplying missing growth factors, as well as by rendering biochemical assistance in other ways, perhaps.

In recent years, Dr. Rayner extended her interests to embrace mycorrhizal associations in a great variety of crops, tropical as well as temperate, and travelled widely in pursuit of her work. To those who knew her well she could be a delightful and stimulating companion, whether in the laboratory or the field, and a visit to her laboratory at Bedford College always gave one plenty to think about. Her long scientific collaboration with her husband, Prof. Neilson Jones, in which temperaments and interests were most happily blended, was a very fruitful one; right up to the last, she had refused to give in to chronic ill-health, and her determination to continue with her work at all costs gained the admiration of all who knew her.

S. D. GARRETT

Mr. G. E. F. Fertel

GEOFFREY FERTEL was born on November 19, 1913, at Bromley, Kent, where his father, who was of Huguenot ancestry, was well known for his musical ability and was organist at the parish church; his maternal grandfather, Benjamin Harrison, was distinguished as an archæologist. While still a small child, he showed unusual interest in natural things and in mechanisms; his love of the countryside was encouraged by his Kentish environment, and at Sevenoaks School he was allowed to spend time on botany instead of games, for which he had no liking.

On entering the Imperial College of Science and Technology, London, Fertel decided to study physics, and was soon recognized as a quick and ingenious constructor and experimenter. Though an indefatigable inquisitor of his teachers, Fertel was never happy until he had 'seen through' a mechanism or a problem in his own way, which usually involved an analogy with some other mechanism or problem, often in another branch of science. He had little interest in formal science, and less in formal people.

After graduation, he remained at the College as a research student, taking part in developing the new technique of time-of-flight measurements with slow neutrons. He left not long before the outbreak of war to join the physics staff of the University of Bristol; but there was already no doubt that his great ability to make apparatus work was matched by a power to see clearly the right technical method to apply to any particular scientific problem. At this time, too, his devotion to scientific things began to leave room for personal friendships that grew in number and strength as time went on. He became noted for original demonstration experiments and for technical jokes such as the perfectly constructed left-handed wood-screw kept in his pocket to hand to a colleague in need, with a right-handed one in the other pocket to be offered as soon as the joke had been enjoyed.

During the War, Fertel worked in the Admiralty Signals Establishment, where his talent for understanding and making things yielded several devices, of which at least one is still an essential part of Service radar equipment. He was glad to return to university life at Bristol and took part in many activities, not only in the laboratory but also in such pursuits as the exploration of caves, both in England and on the Continent. He left Bristol in 1948 to join in the construction and operation of the large cyclotron at the University of Birmingham, and quickly gained the admiration and the affection of his new colleagues. On January 19, 1949, while making adjustments to the cyclotron, he was electrocuted and died instantly.

Fertel left little published work, but will long be remembered as a man of extraordinary energy and skill whose passion was to know and to understand.

NEWS and VIEWS

Botany at Delhi: Prof. P. Maheshwari

Dr. Panchanan Maheshwari, who is well known for his work on angiosperm embryology and cytogenetics, has been appointed to a chair of botany in the University of Delhi. Receiving his early training at Allahabad, he came under the influence of an American botanist, the late Dr. Winfield Dudgeon, and in 1931 was the first to obtain the degree of D.Sc. in botany in the University of Allahabad. As a teacher he served successively as a lecturer and associate professor of botany at Agra College (1930–37). For about two years (1937–39) he was lecturer in the University of Allahabad and for a brief term in Lucknow, later migrating to Dacca as reader in botany and head of the department, where he developed facilities for postgraduate teaching and research. He was recently promoted professor of botany in the University of Dacca and became dean of the Faculty of Science.

Prof. Maheshwari has travelled widely for the sake of developing contacts with colleagues in his own field of research, undertaking two long study tours in Europe (1936–37) and in the United States (1945–47). His original work has been largely influenced by the school of Tischler at Kiel and of Schnarf in Vienna. He has done much, both directly and indirectly, to advance the study of angiosperm embryology in India. He is the author of an advanced text-book on the "Embryology of Angiosperms", which is shortly to be published, and is editing for the *Chronica Botanica* series a "Manual of Angiosperm Embryology" based upon contributions from specialists in many countries of the world. He is president elect of the Section of Botany at the next Indian Science Congress to be held in Poona in January 1950.

Nature Conservancy in Britain

Mr. Herbert Morrison announced in the House of Commons on February 11 that arrangements have been completed for forming a Nature Conservancy, and that a separate committee will supervise activities in Scotland. Membership of the Conservancy will be as follows: Prof. A. G. Tansley (chairman); Mr. A. Anderson, M.P.; Mr. C. Elton; Dr. E. B. Ford; Dr. H. Godwin; Mr. E. H. Keeling, M.P.; Mr. N. B. Kinnear; Prof. R. C. McLean; Prof. J. R. Matthews; Mr. E. M. Nicholson; Prof. W. H. Pearsall; Mr. M. Phillips Price, M.P.; Mr. J. A. Steers; Mr. W. L. Taylor; and Dr. A. E. Trueman. The Conservancy—Mr. Morrison referred to the term as a more convenient title than conservation board—will be responsible for the whole of Great Britain; but as a result of the recommendations of the Scottish Wild Life Conservation Committee, and of consultations with the Secretary of State, activities in Scotland will be supervised by a Scottish committee with the following composition: Prof. J. R. Matthews (chairman); Mr. A. Anderson, M.P.; Mr. H. C. Beresford-Peirse; Dr. F. Fraser Darling; Mr. A. B. Duncan; Dr. D. N. McArthur; Sir Basil H. H. Neven-Spence, M.P.; Prof. A. D. Peacock; Prof. J. Ritchie; Prof. J. Walton; Lord Wemyss and March; and Prof. C. M. Yonge.

Dr. John Berry, who is known for his work in fishery research and for contributions on wild life in Britain, and in 1944 was appointed biologist to the North of Scotland Hydro-Electric Board, has been released to serve as director for Scotland of the Conservancy. It has already been announced that Captain Cyril Diver has been appointed as director-general, with his office at Thorney House, Smith Square, S.W.1. The Conservancy is seeking a charter on similar lines to that of the Agricultural Research Council, with which it will co-operate. The Committee of the Privy Council for Agricultural Research will be reconstituted as the Committee of the Privy Council for Agricultural Research and Nature Conservation, and the Minister of Town and Country Planning will join it in view of its extended responsibilities. The Conservancy will start work at once.

Institution of Mechanical Engineers: James Clayton Prize

The Council of the Institution of Mechanical Engineers has awarded the 1948 James Clayton Prize of £1,350 to Mr. Karl Baumann, for his contributions to the advancement of mechanical engineering science by way of invention, design and investigation, communicated, in part, in a lecture delivered to the Institution in 1948. Mr. K. Baumann is the chief mechanical engineer and a director of the Metropolitan-Vickers Electrical Co., Ltd., Manchester. His professional life has been largely identified with the development of the modern steam power station including steam turbines and boiler plant, and latterly the internal combustion turbine. He received the Institution's premier award, the Thomas Hawksley Gold Medal, for a paper published in 1930. The James Clayton Bequest is for the distribution annually, on research, investigation and the encouragement of mechanical engineering science, of three-quarters of the income of the fund. The remaining quarter of the income is for the award (James Clayton Prize) to a member, associate member, graduate or student of the Institution, who contributes most in the year to modern mechanical engineering science. Previous awards have been made to Sir Frank Whittle (1945), Mr. Hayne Constant (1946), Sir Richard Southwell (1946), Mr. T. E. Beacham (1947), and Mr. J. E. Sears (1947).

Midwest Research Institute

Dr. George E. Ziegler has been appointed director and Dr. Clayton O. Dohrenwend assistant director of the Midwest Research Institute, Kansas City. Dr. Ziegler went to the Institute at the time of its inception in 1945 as executive scientist, having previously been associated with the Armour Research Foundation in Chicago. He is known in scientific circles for his experimental X-ray diffraction studies, and has been acting chief administrator of the Institute since the resignation of Harold Vagtborg some six months ago. Dr. Dohrenwend has been research consultant since going to the Institute in July 1946. He was formerly associated with the Illinois Institute of Technology as director of the Mechanics Department. He is a specialist in the field of engineering mechanics and past president of the Society for Experimental Stress Analysis.

East African Industrial Research Board

The fifth annual report of the East African Industrial Research Board (Pp. iii+28. Nairobi, P.O. Box 1587. 1*s*. 6*d*.), covering the year ended December 31, 1947, includes the report of the acting chairman, Mr. H. B. Stent, the General Laboratory report, the annual report of the Tanganyika Industrial Committee, 1947, and a list of publications on industrial research in East Africa. A departmental report on ceramics details the work carried out on bricks and roofing tiles, domestic pottery, refractories, building materials, glazed wall-tiles and drain-pipes, while a fairly full account is given of work on the extraction of undried pyrethrum flowers, which has given results comparing favourably with existing methods of extracting dried flowers and appears to merit large-scale trials. Work on silicophosphate is also described in detail, including the results of rotary kiln firings, laboratory-scale firings, and of investigations on the fractions of the clinker soluble in water and in citric acid. Investigations on the treatment of effluents from the processing of sisal and coffee have continued, and biological filtration gave promising results for the former. The Tanganyika Industrial Committee reports on the production of totaquina, the final target of 10,000 lb. for which was met early in November, 1947. Other investigations under the Committee related to the assay and manufacture of papain, and the assay and cultivation of pyrethrum flowers. The Board itself at its three meetings during the year focused its attention on negotiations for the early establishment of a permanent East African Scientific and Industrial Research Organisation, and a memorandum was submitted to the East African Governments and to the Colonial Office advocating the establishment of such an Organisation on the lines of other existing inter-territorial research organisations. Stress was laid on the vital need of such work if the large sums of money for the development of the East African territories are to be used to the best advantage.

Parliamentary and Scientific Committee

The annual report for 1948 of the Parliamentary and Scientific Committee records the visit of a deputation from the Committee to discuss with the Minister of Education the position in Britain of colleges of technology. The Minister said that the report of the Committee agreed closely with the policy of the Ministry; but he thought that a National Council of Technology would be too cumbersome. He agreed that the status of technical colleges should be raised, and promised to increase the number of technical State Scholarships immediately the demand and capacity to take advantage of such scholarships existed. Members of the Committee took a very active part in debates on the Development of Inventions Bill, and a critical discussion of the Bill was arranged on May 11. Early in the year a detailed memorandum on current difficulties in the import of scientific books and periodicals was submitted to the Board of Trade, and information collected from scientific bodies about the shortage of paper and facilities for producing scientific books and periodicals was incorporated in a memorandum forwarded to the Lord President of the Council in July. A reply from the Lord President in September stated that the paper allocation for the production of books was practically equal to that used in 1939 and that about double the number of books were being produced. A further memorandum, which, among other recommendations, urged that the criteria to be applied should be whether the output was meeting the greatly increased requirements in Great Britain and overseas for up-to-date scientific and technical information, and not pre-war figures, was submitted to the Lord President in November. A memorandum on steel utilization has also been prepared by the Committee; technical education, the salaries of teaching and research staff in medical schools and universities, and the Veterinary Surgeons Bill have also been considered.

Superconducting Bolometers

During the past few years a sensitive form of bolometer has been developed, at the Johns Hopkins Cryogenic Laboratory, under the direction of Dr. D. H. Andrewes, which makes use of the high variation of electrical resistance with temperature that occurs in the region between the normal- and zero-resistance states of a superconducting material. Tantalum (*Rev. Sci. Instr.*, 13, 281; 1942) has been used successfully, but it requires to be cooled to liquid helium temperatures. Columbium nitride, with a transition temperature at about 15° K., just above the triple point of hydrogen, presents a much less difficult temperature-control problem, and bolometers of very high sensitivity have been made. These should prove useful for the examination of the as yet unexplored region of emission spectra of sources at room temperature, with considerable application in biological research. Recently, a careful study of the infra-red sensitivity of a number of columbium nitride superconducting bolometers has been made by N. Fuson (*J. Opt. Soc. Amer.*, 38, 845; 1948), and the sensitivities have been compared with those of other infra-red detectors. Details of the construction of the bolometers, of the infra-red source, modulator, cryostat, wide-band amplifier, and other auxiliary equipment, together with the experimental procedure, are given. Time constants of 0·7 to 17·0 milliseconds were observed. For the purposes of comparison, a factor of merit, based on the reference conditions suggested by R. C. Jones (*J. Opt. Soc. Amer.*, 37, 888; 1947) and R. Havens (*J. Opt. Soc. Amer.*, 36, 355 A; 1946), is defined. The nine most sensitive of the twenty-five superconducting bolometers examined had factors of merit between 1·3 and 14·0.

Functional Embryology

The New York Academy of Sciences has issued a publication entitled "Recent Studies in the Mechanisms of Embryonic Development" (*Ann. New York Acad. Sci.*, 49; 1948) the title of which is self-explanatory. It contains nine contributions by separate authors each dealing with one aspect of the general subject, and each article is well illustrated and provided with a brief summary of the relevant work and a bibliography. The subjects dealt with include: the early organisation and differentiation of prospective areas in the developing eggs of *Nereis*, the amphibians *Triton* and *Ambystoma*, and the chick; biochemical differentiation; the role of nerves in amphibian limb regeneration; and locomotor responses and retinal development in normal and transplanted retinæ. Incidentally the name '*Amblystoma*' is used in two of the papers instead of the correct form *Ambystoma*. It is difficult to pick out for special notice any one paper; but that by S. R. Detwiler on "Quantitative Studies on Locomotor Responses in Amblystoma Larvæ following Surgical Alterations in the Nervous System" with its reconstructions is of particular interest in view of the recently published book by C. Judson Herrick on the brain of *Ambystoma*.

National Tsing Hua University: Science Reports

The three series of the *Science Reports of the National Tsing Hua University* (Series A: mathematics, physics and engineering; Series B: biology and psychology; Series C: geology, geography and meteorology), published for several years before 1937, were suspended during 1937–45, with the exception of one issue of Series A printed in September 1940. With the return of the University to Peiping, publication of the three series has been resumed, and, so far, two issues of Series A (**4**, Nos. 4, 5 and 6; 1947, and **5**, No. 1; 1948) have been received. The papers appearing in the 1947 issue were originally intended for publication in 1941 to commemorate the thirtieth anniversary of the University (1911–41); but, although the University was then at its war-time home at Kunming, the *Reports* were being printed in Shanghai, which was overrun by the Japanese military forces, and therefore they could not be published. The *Reports*, which are in English or French, indicate clearly how, in spite of extremely trying conditions, research work of a high standard continued to be carried out in the University.

Melbourne Seismological Station

THE Council of the University of Melbourne recently approved an arrangement whereby the seismograph of the former Melbourne Observatory, which the University accepted from the Government of Victoria when the Observatory was disbanded in 1941, will in future be in the care of the Department of Geology of the University. A member of staff of the Geology School (Mr. A. J. Gaskin) has been nominated seismologist, and a technical assistant provided for him. It is hoped that the issuing of seismological bulletins will be commenced in June 1949, and that the issue will thereafter be at regular intervals, probably quarterly. Instrumentation remains unchanged for the present. All records later than those listed in the last leaflet issued for the Observatory (July 2, 1940) have been inspected, and information regarding them may be obtained on application. Correspondence (including requests for the receipt of bulletins) should now be addressed to the Seismologist, Department of Geology, University of Melbourne, Carlton, N.3, Victoria, Australia.

Sir D'Arcy Thompson: Commemoration Fund

SOME of the many friends and pupils of the late Sir D'Arcy Thompson have issued an appeal for contributions to a commemoration fund which will be used for the following purposes: (1) presentation of a bronze head to the University of St. Andrews; (2) presentation of a portrait in oils to University College, Dundee; (3) memorial prizes in the Departments of Natural History at St. Andrews and Dundee. The printed announcement of the fund contains excellent reproductions of the portrait and of the clay model of the head. It has not been possible to communicate personally with all of Sir D'Arcy Thompson's friends, but copies of the announcement may be obtained from the Secretary of the Fund, D. R. R. Burt, Department of Natural History, the University of St. Andrews.

Colonial Service: Recent Appointments

THE following appointments in the Colonial Service have been announced: D. Leuchars, assistant conservator of forests, Uganda; E. Q. O'B. Smith, assistant conservator of forests, Northern Rhodesia; D. A. Aitkenhead, geologist, Gold Coast; C. Facer, surveyor, Uganda; K. T. Pugh, surveyor, Tanganyika; A. H. Ward, surveyor, Northern Rhodesia; S. E. Brinkman, meteorological assistant, East African High Commission; F. J. Cornish, meteorological assistant, East African High Commission; A. P. Johnson, assistant meteorologist, Nigeria; E. B. Powell, assistant controller (radio), Federation of Malaya; C. J. M. Simpson, entomologist, East African High Commission; S. D. Ross (principal agricultural officer, Nigeria), assistant director of agriculture, Nigeria; F. W. Roe (geologist, Federation of Malaya), chief geologist, Borneo; H. R. Binns (deputy director of veterinary services, Palestine), scientific officer, East African Veterinary Research Organisation; R. M. Gambles (veterinary officer, Cyprus), senior veterinary research officer, Nigeria; R. E. Gould (senior poultry and bee-keeping officer, Palestine), fisheries officer, Tanganyika; W. D. Silvera (medical officer, Jamaica), senior lecturer in pathology, University College, Ibadan, Nigeria.

Announcements

THE following appointments have been made in the University of London: Mr. F. Wormald, to the University chair of palæography tenable at King's College as from January 1, 1950. Dr. G. L. Brown, of the National Institute for Medical Research, to the Jodrell chair of physiology tenable at University College as from October 1, 1949. The title of professor of logic and scientific method in the University has been conferred on Dr. K. R. Popper in respect of the post held by him at the London School of Economics.

THE Brewster Gold Medal of the American Ornithologists' Union has been awarded to David Lack, director of the Edward Grey Institute of Field Ornithology at Oxford, for his book "Darwin's Finches", published in 1947 by the Cambridge University Press. The Medal is awarded for the most important work relating to the birds of the western hemisphere published during the preceding six years.

IN co-operation with the University of Edinburgh and the East of Scotland College of Agriculture, the Association of Agriculture is arranging a Conference, intended primarily for teachers, on "Applied Biology, Geography and Education" at the College of Agriculture, 13 George Square, Edinburgh, during April 12–14, 1949. The registration fee is 2*s.* 6*d.*, which includes the inaugural dinner, and tickets and further details may be had on application to Alexander Hay, General Secretary, Association of Agriculture, 238–240 Abbey House, 2 Victoria Street, London, S.W.1.

APPLICATIONS are invited for Lady Tata Memorial Fund grants and scholarships to scientific workers of any nationality for research in diseases of the blood, with special reference to leukæmia, in the year beginning October 1, 1949. Grants are made for research expenses, and scholarships are awarded as personal remuneration, their normal value being £400 per annum for whole-time research, or less for part-time work. Applications must be submitted before March 31, 1949, and the awards will be announced in June. Further particulars and forms of application may be obtained from the Secretary of the Scientific Advisory Committee, c/o Medical Research Council, 38 Old Queen Street, Westminster, London, S.W.1.

ERRATUM.—Referring to his communication entitled "*Trypanosoma heptatretæ* sp.n., a Blood Parasite of the Hagfish" (*Nature*, **161**, 440; 1948), Mr. Marshall Laird has written proposing amending the name to *T. heptatreti* in accordance with the International Rules of Zoological Nomenclature.

An Electron Microscope Study of the Nuclear Membrane

THE giant nuclei of full-grown oocytes of Amphibia offer unique opportunities for anatomical and physiological study, on account of the relative ease with which they may be isolated and handled. The material for the present study was obtained from *Triturus cristatus* and *Xenopus lævis*.

Under a low-power binocular, the nuclei are isolated into distilled water with the aid of needle and forceps. In this medium the nucleus rapidly swells, and meanwhile adhering cytoplasmic materials may be pumped away by means of a pipette. The entire nucleus, freed from cytoplasm, is then transferred to fresh distilled water: a copper specimen grid is now placed in the same container, and the nuclear membrane ruptured and stretched out over the grid by means of a pair of fine-pointed tungsten needles. After the stretched membranes have been pumped free from nuclear sap, they may be dried directly or after prior fixation. For the preservation of fine structure, fixation appears to be necessary.

Grids carrying nuclear membranes were examined in a Siemen's electron microscope operating at 52 kV., the magnification of the photographic negative being 12,000–15,000 diameters. The photographs, three of which accompany the present letter, indicate that the nuclear membrane is a compound structure. One component is a porous sheet, the pores being approximately 300 A. in diameter in hexagonal array, with a repetition distance of about 800 A. It must be borne in mind, however, that the membranes are readily distorted during preparation, the hexagonal arrangements being frequently disturbed. The other component is a membrane with no evident fine structure. This closely over- or underlies the porous membrane; but the relative positions of the two are not yet known. Under certain as yet ill-defined conditions, the porous membrane disintegrates in the process of specimen preparation, leaving the structureless membrane only.

It may be presumed that the structureless component determines the permeability properties of the nuclear membrane. Other investigations have shown that egg albumen cannot penetrate this membrane, and hence even if a porous structure is present it would be beyond the limits of resolution of the existing microscope. The visibly porous membrane, on the other hand, probably acts merely as a mechanical support for the structureless membrane.

This work is being continued, and a detailed account will be published elsewhere.

X-Ray Diffraction Study of the Structure of Bacterial Flagella

FOLLOWING on the demonstration by Gard[1] of the practicability of obtaining the flagella from bacterial cultures in fair yields and in a highly purified state more detailed chemical and physicochemical investigations are now being undertaken under a scheme supported by the Swedish Natural Science Research Council. Data have already been published by Weibull and Tiselius[2] on the flagellar material prepared by Gard from *Salmonella paratyphi* B., and by Weibull[3] on the flagella of the harmless and easily cultivated *Proteus vulgaris*. The present communication is a preliminary account of an X-ray diffraction study of flagellar material prepared at Uppsala and brought to Leeds.

We have so far examined the flagella of *Proteus vulgaris* and *B. subtilis*. The method of preparation was as already described[3]; here we need only say that the final product from *Proteus*, for example, forms a colourless stable viscous solution with strong flow birefringence. It gives a precipitation reaction with a *Proteus* × 19 *H* rabbit antiserum, has a nitrogen content of 15·7–16·1 per cent, shows only traces of phosphorus and 1 per cent carbohydrate at the most, and contains no tryptophane and no purine or pyrimidine bases: it has the characteristics of a protein but not of a nucleoprotein. When examined in the electron microscope, essentially only one structural element is seen—long flexible threads of the same thickness as the flagella on the bacterium, but shorter, presumably owing to breakage during the purification process.

The flagella are also reversibly precipitable with ammonium sulphate and show electrophoretic mobility; in brief, they behave like long macromolecules and therefore invite X-ray study by just those tech-

Fig. 3. Partial β-diagram obtained after squeezing moist film of *Proteus* flagella between pieces of plate glass

niques that we have evolved for myosin, sodium thymonucleate, and many other similar preparations. In these preliminary experiments we have simply made very thin films by allowing small pools of the viscous solution to dry on microscope slides previously treated with dichloro-dimethyl-silane to make them water-repellent. The films were then easily detached, and specimens suitable for X-ray examination were built up from several strips lying flat on top of one another. It should be emphasized that the drying process causes no significant deterioration: the films could be redissolved in water and the solution still showed flow birefringence.

When the solution is dried to a thin film the flagella are brought to lie approximately in one plane, and a pseudo-fibre diagram should be obtained when the X-ray beam is parallel to this plane. Figs. 1 and 2 illustrate two of the photographs we have obtained in this way. Detailed analysis will be given later (in any case the experiments are still proceeding with the view of getting better orientation and higher resolution), but already it may be stated that the diagrams conform in the main to the α-type characteristic of the great family of elastic fibrous proteins that we have called the keratin–myosin–epidermis–fibrinogen group[4]. Not only is the now well-known meridional reflexion at about 5·1 A. clearly in evidence, but also there are at least half a dozen other reflexions that find their counterparts in hair and muscle photographs and particularly in MacArthur's high-resolution diagram of porcupine quill[5]. In addition, we have succeeded in stretching *Proteus* flagella into the β-form—not as yet by direct pulling, to be sure, but by squeezing moist film at room temperature between pieces of plate glass, after the procedure found effective with myosin[6], for example. In our experiments so far, the resulting squeezed film was too fragile to mount intact for the purpose of taking an X-ray photograph with the beam parallel to the surface, and we have had to be content with a powder photograph (Fig. 3); but there is no doubt that the diagram reveals appreciable transformation into protein of the β-type; it is, in fact, very like what is found after heating the flagella to about 100° (cf. myosin again).

It follows that, from the X-ray point of view at least, the flagella on *Proteus* and *B. subtilis* are of the nature of primitive hairs or muscles—and it is not of basic importance which name is used, since X-ray and related studies indicate that the whole of the keratin–myosin–epidermis–fibrinogen group is derived from a single master plan[4]. From electron micrographs taken at Leeds of *Proteus* flagella and tobacco mosaic virus in the same field, it is seen that the former (when dry) are definitely the thinner of the two; their thickness is about four-fifths or five-sixths that of the virus particles (150 A.)—say, roughly, 120 A. Conceivably, therefore, these flagella may even be described as 'monomolecular' hairs or muscles, for their thickness falls within the order of size of the largest side-spacings[5,7,8] that have been observed or inferred for other members of the keratin–myosin–epidermis–fibrinogen group; and besides, there is a rather surprising detail and sharpness about the photographs which suggests a structural simplification as compared with hair keratin, for example. There are reasons for thinking that the latter is a polyphase system built of polypeptide grids (or combinations of grids) of similar form but varying amino-acid constitution[5,9]; but it may be that the framework of a flagellum is constructed from only one such type of component.

At all events, it is clear that a most promising new field is opened up, with a new approach to the mechanics of protein structures and probably fresh light on the problem of the muscle machine. We are strengthened in this last suggestion by the curious fact that though the normal flagella diffraction diagram, as stated above, is composed mainly of reflexions conforming to the α-form of the keratin–myosin–epidermis–fibrinogen group, what appears to be the characteristic backbone reflexion of the β-form is also present, and indeed not in its usual position on the equator, *but on the meridian*. Such a transposition was observed some years ago by Rudall[10] in supercontracted preparations of epidermis, myosin, fibrinogen and fibrin, and he interpreted it as direct experimental evidence in support of the suggestion[4] that the α-form may shorten simply by developing longer transverse folds. If Rudall's interpretation is correct—and there is a great deal to be said for it—then it is tempting to suppose that the flagella diffraction diagram reveals also a partial state of contraction.

We should like to express our indebtedness to Mr. E. Beighton for his skilful aid in taking the X-ray

photographs, and to Dr. R. Reed and Mr. A. Millard for the electron micrographs of *Proteus* plus tobacco mosaic virus, also to Profs. Gard and Tiselius our appreciation of their encouraging interest. One of us (C. W.) would also wish to thank the Swedish Natural Science Research Council for a grant enabling him to take part in the investigation.

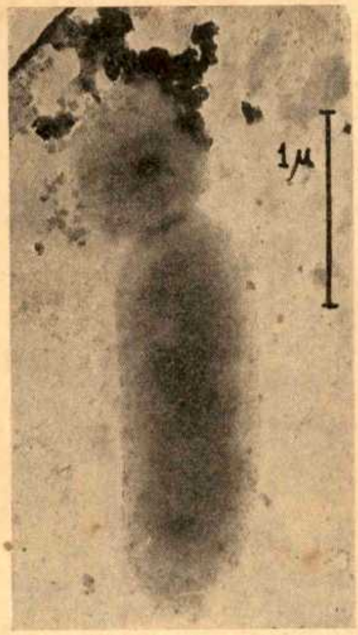
Sectioning of the Bacterial Cell for the Electron Microscope

The introduction of a technique for cutting ultra-thin sections of biological tissue with the conventional microtome[1] has also made feasible the sectioning of isolated cells for the electron microscope. Bacterial cells were chosen as a first example because of convenient size, ease of handling in large numbers, and because of the intrinsic importance of any new approach to the problems of bacterial morphology.

B. megatherium was grown on nutrient agar, and when the culture was approximately twenty-four hours old, quantities of cells were transferred with a wire loop to a 5 per cent formalin solution in a centrifuge tube. After one hour of fixation the cells were centrifuged for five minutes at 20,000 r.p.m. and the formalin then poured off. Dehydration with a graded series of alcohols was then carried out, using the centrifuge to keep the bacteria together in the transition from one solution to another. Impregnation with Mallinckrodt 'Parlodion' followed, starting with 3 per cent 'Parlodion' in equal parts of ether-alcohol and ending in a 12 per cent solution. Transition from 6 to 12 per cent 'Parlodion' was accomplished by evaporation of the solvent. After one day in 12 per cent 'Parlodion', chloroform was used as a hardening agent, after which the hardened block was broken out of the centrifuge tube. Impregnation of the block with paraffin (m.p. 65°) followed, after going through a carbol-xylol bath to remove the last traces of water. The doubly embedded block was finally mounted on a plastic pillar which could be clamped in the microtome.

·1μ One-tenth micron sections were cut as described in ref. 1, and were flattened on a microscope slide, using needles under a binocular dissecting microscope. The paraffin was removed with benzol, after which the slide was dipped vertically into a beaker of dilute (0·2 per cent) collodion in amyl acetate. This replaced the original collodion with a thinner and more homogeneous film, which was then floated off on a clean water surface. Microscope specimen screens (200 mesh) were placed on the sections and the entire film inverted and mounted on another slide. After drying, the specimens were ready for examination in the electron microscope.



Transverse and longitudinal sections of *B. megatherium* approximately 0·1 microns thick. × 25,000; 50 kV. Note similar density and detail in the two cells

Since the cells were oriented at random in the block, the sections might be expected to show cells cut at various angles. The accompanying photograph shows two cells which were nearly at right angles in the block, giving rise to a longitudinal and a transverse cut in the same field of view. Sufficient internal detail is visible in both cells to make it clear that the sections are adequately thin for effective use with a 50-kV. electron microscope. Much further work will, of course, be necessary to establish the significance of the internal detail observed in an experiment of this type. It is the purpose of this note merely to describe a new technique, which may profitably be used in the study of bacterial morphology and the relationships of bacteria and bacterial viruses.

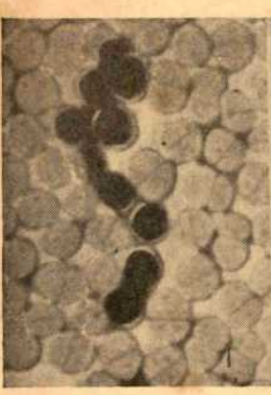
A Method of Sectioning Bacteria *in situ* for Electron-microscopical and Cytochemical Investigations

A method has been developed for preparing sections of bacterial cells for observation with the electron microscope. An impression preparation of a young growing culture is made on a polished glass surface and fixed with osmic acid. On to this a beryllium film is evaporated by means of Hast's method[1]. The beryllium film is then stripped from the glass surface and frequently carries with it a section through the bacterial cells with their relationships undisturbed. During the evaporation of the beryllium, some atoms of the metal penetrate the surface of the cells, thus anchoring a layer of the bacterial cytoplasm to the film. This layer is normally removed when the film is stripped, although sometimes whole cells adhere to the film as shown in Fig. 1. The process can be repeated and a further section of the same group of cells obtained. Fig. 2 shows such a section from a young and rapidly dividing culture of Enterococci (*Str. fœcalis*). The cell appears to contain a round, well-defined body which seems to divide at the same time as the cell. It is further possible to treat the sectioned bacteria with agents (such as enzymes or antibodies) and to re-examine the sections on the beryllium film. The section can be washed with buffers and digested with enzyme preparations. It should thus be possible to combine this technique with cytochemical investigation. The result of such studies will be described in a further communication.



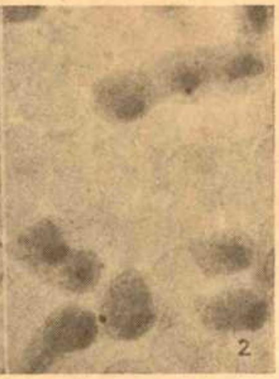


Fig. 1. Surface section through Enterococci (5-hr. culture). × *c.* 9,000

Fig. 2. Third section through Enterococci (5-hr. culture). × *c.* 12,000

I am deeply indebted to Prof. M. Siegbahn, who has constructed the microscope with which the pictures were taken and who has placed all facilities at my disposal, and to Prof. N. Hast, who encouraged me to use the beryllium as supporting membrane. The photographs were taken by Mr. Rosenquist.

Polarization of Radiation from Distant Stars by the Interstellar Medium

PHOTOMETRIC observations for the detection of partially polarized radiation from eclipsing binary stars have been in progress at Yerkes Observatory, of the University of Chicago, for several years with the view of establishing observationally the effect pointed out by Chandrasekhar that the continuous radiation of early-type stars should be polarized[1,2]. On the assumption that the opacity of early-type stars is due to scattering by electrons, the continuous radiation emerging from a star should be polarized with a maximum of polarization of 11 per cent at the limb. Since the presence of this polarization can be detected only when the early-type star is partially eclipsed by a larger late-type companion of the system, the effect is masked by radiation from this companion, so that the expected maximum observable effect is only of the order of 1·2 per cent in the one case investigated (*RY* Persei).

However, the observations made in connexion with this problem have led to the detection of a new phenomenon which appears to have a bearing on the constitution of interstellar matter. Three Wolf–Rayet spectroscopic binaries (two of which are known to be eclipsing) in Cepheus were observed with the following results:

Star	Polarization	
	Per cent	Position angle
CQ Cep.	10·0	62
BD + 55° 2721	8·0	44
WN Anon*	12·5	44

* No catalogue number.

If the polarization were associated with the individual stellar systems, there should be a change in the polarization, in position angle and amount, with the phase of the binary motion. However, no such change was observed. In order to determine possible systematic errors in the receiving equipment, I investigated the polarization of comparison or control stars of similar colour and brightness. With the exception of *BD* + 55° 2723, no significant polarization was found in the control stars. *BD* + 55° 2723 gave 3 per cent polarization with a position angle of 44°. This particular star differs from the other control stars in that it is a giant, and is consequently more distant than the other control stars, which belong to the main sequence.

Similar observations were made on a group of Wolf–Rayet stars in Cygnus, which showed no significant polarization, while two stars in Scutum gave positive results. Other regions, such as the double cluster in Perseus, also show polarization with values ranging up to 12 per cent.

We conclude from the positive and negative results quoted that the measured polarization does not arise in the atmosphere of these stars, but must have been introduced by the intervening interstellar medium. If this conclusion is accepted, a new factor in the study of interstellar clouds is introduced. Further observations are in progress for relating this phenomenon with other observable characteristics of the interstellar medium. The results already at hand indicate that the plane of polarization approximates to the plane of the galaxy.

Possibility of a Phase Transition in the Pure Helium Isotope of Mass 3

Sydoriak, Crilly and Hammel[1] have reported the preparation and separation of the pure helium isotope of mass 3. They have succeeded in condensing it and have determined its vapour pressure in the temperature range 1·21°–3·34° K. (the critical temperature) and its boiling point at 3·20° K. These vapour pressure measurements appear to have interesting consequences with regard to the possibility of a phase transition in the pure helium isotope of mass 3. They provide evidence for such a transition at 1·9° K. In this communication, the possibility of this transition is first examined, the vapour pressure equations in the two ranges 1·2–

1·9° K. and 1·9–3·20° K. are given, and a few remarks are made about the theoretical implications of the existence of a phase transition in the pure helium isotope of mass 3.

For a substance the vapour of which behaves as a perfect gas, the vapour pressure equation has the form

$$\log p = 2{\cdot}5 \log T + a/T + i, \qquad (1)$$

where i is the chemical constant. In fitting a curve of this sort to vapour pressure data for helium-4, it has been found[2] that the constants have nearly the theoretical values. This gives some confidence in using a formula of this theoretical form, and it seemed to be worth while to do so for the vapour pressure data for the pure helium isotope of mass 3. The simplest way to do this is to plot the values of

$$\log p - 2{\cdot}5 \log T \qquad (2)$$

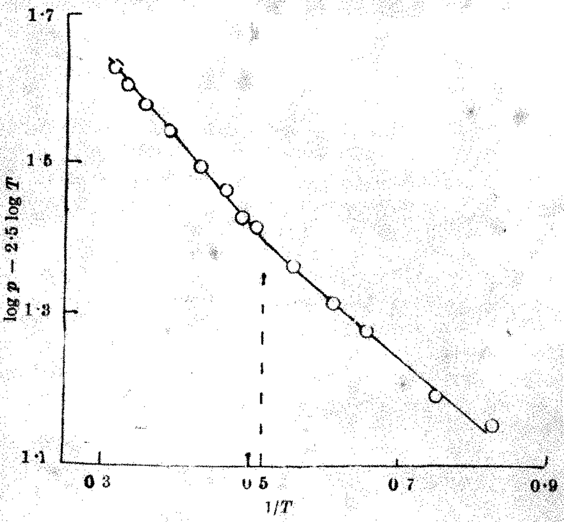
as a function of $1/T$. When this was done for the data on helium-3, it was immediately apparent that all the data did not lie on a single straight line. The experimental points below about 1·9° K. were found to lie on one straight line, while those above 1·9° K. were found to lie on a different straight line, as shown in the accompanying diagram. Non-ideality of the vapour would give a curve convex to the axes, and if there is a wide scatter of the experimental points this may be the explanation. The reported values do adhere so closely to straight lines that it seems improbable that the experimental scatter has fortuitously caused this. The vapour pressure equations for pure helium-3 in the temperature ranges indicated were found to be

$$\log p = 2{\cdot}5 \log T - \frac{0{\cdot}79}{T} + 1{\cdot}795 \qquad (3)$$
$$(1{\cdot}21 < T < 1{\cdot}9^\circ \text{ K.}).$$

$$\log p = 2{\cdot}5 \log T - \frac{1{\cdot}10}{T} + 1{\cdot}960 \qquad (4)$$
$$(1{\cdot}9 < T < 3{\cdot}20^\circ \text{ K.}).$$

In the accompanying table the values of p calculated from equations (3) and (4) are tabulated against the corresponding experimental values. Comparison of the values given in the second and third columns of the table indicates the faithfulness with which equations (3) and (4) represent the experimental data.

The occurrence of the kink shown in the diagram of the plot of expression (2) against $1/T$ is consistent with what would be observed if pure helium-3 underwent a phase transition of the second or higher order at this temperature. The vapour pressure data which have been reported[1] suggest that pure helium-3 exhibits a phase transition at about 1·9° K. This conclusion must, however, be regarded as somewhat speculative until measurements of the physical properties (for example, specific heat, density) have been made. In particular, it would be worth while to look for discontinuities in their temperature variation in the neighbourhood of 1·9° K.



Temperature (° K.)	Pressure (mm. mercury) Calculated	Observed
1·211	22·5	23
1·334	33	32
1·524	54	54
1·635	70	70
1·795	98	99
1·977	139	141
2·047	158	159
2·152	190	195
2·327	253	255
2·580	364	366
2·817	493	495
3·032	630	634
3·201	756	764

The conclusion that the vapour pressure data indicates a lambda-transition in pure helium-3 is put forward with all due caution. In this connexion it must be remembered that the lambda-transition in the isotope of mass 4 was not deduced from any discontinuity in the temperature derivatives of the vapour pressure. For helium-4, such a discontinuity was, in fact, detected only after the phase transition at 2·19° K. had been discovered by other means. The discontinuity shown in the gradient of the vapour pressure measurements on helium-3 is greater than that shown by the vapour pressure of helium-4 at its lambda point.

It has generally been assumed that the lambda-transition in helium-4 is a manifestation of Bose–Einstein condensation. In this connexion it should be noted, however, that the Bose–Einstein condensation gives the wrong kind of transition[4], that it has never been demonstrated to exist for interacting particles and that 'demonstrations' of its existence for non-interacting particles are far from rigorous[5]. If helium-3 also shows a second-order phase transition, this would provide *prima facie* evidence that the *existence* of such a phase transition could not be a consequence of the particular quantal statistics obeyed by the assembly of particles. It would thus rule out any attempt at a theory of the phase transition in helium-4 which depends on the fact that helium-4 atoms obey Bose–Einstein statistics. It would be tempting to suggest that if helium-3 has a phase transition in the neighbourhood of 1·9° K., then below this temperature it will exhibit 'superfluid' properties analogous to those shown by helium-4 below 2·19° K., but no such conclusion can be deduced from the existing data. Although it is probable that below such a transition temperature helium-3 would have unusual properties, their precise nature could be determined only by experiments explicitly designed to examine this. The point is that, although a phase transition of the second order in helium-3 would indicate that the *existence* of such transitions is independent of the statistics obeyed by the assembly of particles, the particular properties shown by the assembly below the transition temperature may well depend on these statistics.

Note added in proof. In discussion of these results with Prof. Simon, he has pointed out that the slopes of the two lines indicate that if the effect is genuine it corresponds to a *defect* of specific heat.

Crystal Structure of Strontium Laurate

STRONTIUM soaps of even-n fatty acids from caproic to stearic were examined by X-rays; they exhibit several crystallographic forms. Form A is obtained by precipitation from an aqueous solution of a sodium soap; the long spacings follow a law, $d = 5{\cdot}879 + 2{\cdot}475\,N$, where N is the number of carbon atoms in the corresponding fatty acid. Form B follows a law, $d = 3{\cdot}95 + 2{\cdot}447\,N$; it can generally be obtained by heating A. The forms show a certain amount of variability of their powder patterns, the causes of which are not yet known. The increment of their long spacings indicates that in both forms the hydrocarbon-chain axes are perpendicular or nearly perpendicular to the ionic sheet planes; they differ in the structure of the ionic sheet or arrangement of the CH_3 end-groups rather than in their angle of tilt. Strontium caproate and one sample of myristate gave patterns indicating the existence of further forms.

Single crystals of the form A of strontium laurate were grown from alcoholic solution. They are long thin plates; a twinned crystal was also found. Rotation photographs, zero and higher layer Weissenberg photographs were taken about the a and c axes using nickel-filtered copper $K\alpha$ radiation. The crystals are monoclinic and the cell dimensions are: $a = 7{\cdot}803$ kX., $b = 70{\cdot}86$ kX., $c = 4{\cdot}75$ kX., $\beta = 102° \, 36'$; density (meas.) 1·27 gm./c.c., (calc.) 1·25 gm./c.c. (assuming four molecules $Sr(C_{12}H_{23}O_2)_2$ per unit cell).

There are many absent reflexions, including $(0k0)$ absent when k is odd and $(h0l)$ absent when $h + l$ is odd. The space group is thus probably $C^5_{2h} - P2_1/n$. Further absences can be explained by assuming that for each atom at x, y, z, there is another atom at $\pm x \pm \frac{1}{4}, y + \frac{1}{2}, z$. This limits the position of the strontium atom to certain special positions. The chains are oriented along the b-axis, which roughly corresponds to the length of four fatty-acid chains.

The intensities of the reflexions were estimated by eye. The y co-ordinates of the atoms were approximately determined by a modified Booth method of steepest descents. The calculations were made on our mechanical structure-factor calculating machine. Probable signs of the $(0kl)$ reflexions were then obtained from the position of the strontium atom, and a Fourier projection on the bc face was prepared by trial and error. The average distance between two alternate carbon atoms in the undistorted part of the chain is 2·605 kX. This compares well with the distance 2·593 kX. found by us in potassium caprate.

We are indebted to Mr. T. R. Lomer for valuable help.

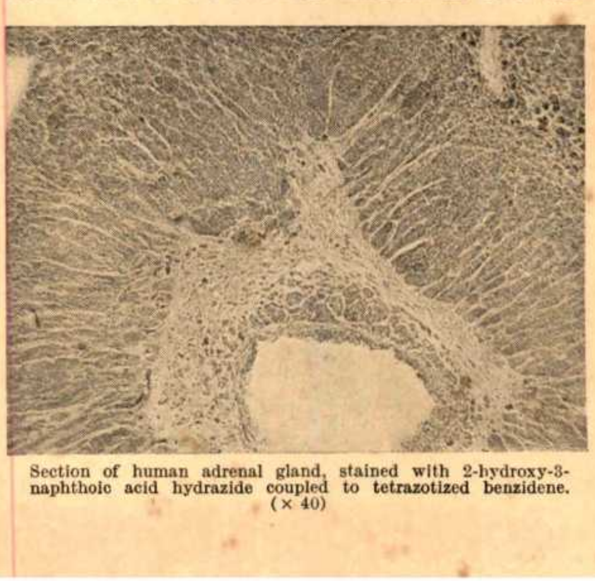
Histochemical Demonstration of Ketosteroids in the Adrenal Cortex

VARIOUS attempts have been made to develop a histochemical method for demonstrating the presence of ketosteroids within the cells of the adrenal cortex[1-7]. These have depended on the formation of coloured hydrazones of the ketosteroids. The low staining intensity of the hydrazones and the minute quantities of the ketosteroids present in the cells have rendered it difficult to locate with accuracy the chromogenic material except in relatively thick sections. Coloured compounds of much greater intensity can be produced if the aryl-hydrazones of the ketosteroids are coupled with diazonium salts. Any degree of solubility can be conferred on the final coupled compound by selecting the most suitable diazonium salt. This permits of the staining of blocks of fixed tissues, the use of paraffin embedding, counterstaining of the sections and clearing and mounting by the usual techniques.

An example of the use of this method is as follows. Formalin-fixed tissue, thoroughly washed in running water, is sectioned on the freezing microtome. The sections (5 μ) are allowed to remain overnight in a saturated aqueous solution of 2-hydroxy-3-naphthoic acid hydrazide[8] and washed in $N/100$ hydrochloric acid and then in distilled water to remove excess reagent, immersed in a solution of 0·4 per cent sodium hydroxide and transferred to a dilute solution of the diazonium salt. This may be prepared from a stabilized diazonium salt, or the following method may be used: 1 m. equiv. of the primary aromatic amine is dissolved in 2·5 ml. N hydrochloric acid (2·5 m. equiv.), and 70 mgm. sodium nitrite (1 m. equiv.) dissolved in 1 ml. distilled water is added to bring about diazotization. Excess nitrous acid would lead to rupture of the hydrazone linkage[9] and is disposed of by the use of sulphamic acid. Approximately 0·5 ml. of the diazonium salt solution added to 250 ml. of distilled water provides a suitable concentration for coupling. If the diazonium salt solution is too strong, staining tends to be patchy. The sections may then be counterstained, cleared and mounted in the usual way. The intensity of the reaction is improved if, before coupling, the sections are put into distilled water to which tincture of iodine is added until a faint straw colour is obtained. After five minutes, 1 per cent sodium thiosulphate solution is added, drop by drop, until the solution is cleared. The distribution of the coloured material in otherwise



Section of human adrenal gland, stained with 2-hydroxy-3-naphthoic acid hydrazide coupled to tetrazotized benzidene. (× 40) unstained adrenal tissue is illustrated in the accompanying figure. The specificity of this colour reaction for ketosteroids is being investigated.

The principle of coupling the hydrazones of ketosteroids with diazonium salts to form coloured azo-derivatives has been found to be applicable also to the investigation of the ketosteroids of body fluids. Estimation of the ketosteroids may be carried out either by fluorimetry of the hydrazones or by colorimetry of the azo-derivatives. Chromatographic separation of mixtures of ketosteroids is possible by using a diazonium salt with the necessary solubilizing properties. The intense colour of the azo-derivatives renders their recognition easy, even when present only in small amounts. Alternatively, chromatographic separation of the hydrazones of the ketosteroids can be effected. The migration of these compounds can be followed by making use of their fluorescence under ultra-violet light. Work along these lines is proceeding.

Reversible Action of D.D.T.

Some unusual relationships between temperature, cuticle permeability, and metabolic activity have emerged from a study of the action of D.D.T. on resistant insects. Observations that the primary stages of D.D.T. poisoning are reversible have provided a clue to the mode of action of this substance and related compounds, which is analogous to that of liquid fat-solvent narcotics. The supporting evidence may be briefly summarized as follows.

Mature *Calliphora erythrocephala* blowfly larvæ were extremely resistant to the contact action of excess crystalline D.D.T., and they pupated and metamorphosed normally within two to three days (20° C.). Paralysis followed exposure to a higher temperature (36° C.) for two hours, but only after the temperature was lowered (20° C.). The larvæ recovered when the temperature was raised. The experiment shows that the permeability of the cuticle to D.D.T. is increased at high temperatures, and since the uptake of crystalline D.D.T. involves a solubilization in the cuticle lipids, the change is consistent with an increase in the mobility of the lipid molecules in the outer epicuticle[1].

The response shown to change in temperature was reversible many times, suggesting that paralysis represents an equilibrium condition in which the D.D.T. present in the cuticle lipids acts selectively on the peripheral nervous system, for there was no interference with pupation, or with metamorphosis. The equilibrium condition may be varied experimentally by: (*a*) detoxication of D.D.T. at the site of action, (*b*) increase in the storage capacity of the cuticle lipids by fat-solvent action, and (*c*) decrease in the storage capacity of the lipids by adsorption displacement of the more mobile components on to 'inert' adsorbent powders. Factors (*a*) and (*c*) antagonize D.D.T. activity; (*b*) increases D.D.T. activity.

(*a*) When the cuticles were painted with a solution (5 per cent) of caustic potash, the paralysed larvæ recovered almost immediately. Presumably the D.D.T. inside the cuticle was hydrolysed *in situ* to the inactive derivative, αα-*bis*-(*p*-chlorophenyl)-ββ-dichloroethylene[2]. This detoxication response indicates that interference with metabolism is primarily reversible.

(*b*) When immersed in a solution (2 per cent) of D.D.T. in kerosene, *Calliphora* larvæ were paralysed within twenty to thirty minutes (20° C.). They did not recover when the temperature was raised. Under these conditions, the kerosene alone is inactive, but it greatly increases cuticle permeability, so that a higher concentration of D.D.T. accumulates at the peripheral nervous system[3].

(*c*) Adult *Calliphora* flies were paralysed rapidly (15–20 min.; 20° C.) by contact with excess crystalline D.D.T.; but if they were first sprinkled lightly with fine alumina powder, the time for the onset of paralysis increased two to four times; chalk and talc, which do not adsorb the cuticle lipids, increased paralysis time slightly by a physical diluent action on the D.D.T., which was overshadowed by the adsorption effect with alumina[1]. Partial recovery from paralysis occurred when the temperature was raised, and the effect was reversible.

These results may be interpreted in terms of the dynamic balance between a rate of D.D.T. activity and a rate of metabolism, both being dependent on temperature. With the resistant larva, the temperature coefficient of D.D.T. activity is smaller than that of metabolic activity, so that the critical metabolic level essential for nervous co-ordination is attained at high, but not at low, temperatures. The reverse relationship holds for kerosene-sensitized larvæ and flies, where D.D.T. activity remains a limiting factor with temperature change; the insects do not respond to a rise in temperature, or to treatment with alkali. Alumina treatment decreases the coefficient of D.D.T. activity, so that the temperature response is shown.

A guide to the nature of the interference in oxidative metabolism was obtained from the observations that the symptoms of D.D.T. paralysis are very similar to the unco-ordinated 'tremors' shown by insects recovering from the narcotic effects of ether, chloroform, or amyl alcohol. It is generally agreed that fat-solvent narcotics exert a relatively non-specific action on intracellular respiratory systems by inhibiting the dehydrogenase systems, such as succinic dehydrogenase, which reduce cytochrome, and these reducing systems show a high temperature coefficient of activity[4]. The average rate of uptake of oxygen by mature *Calliphora* larvæ at 20° C. (measured by a metal micro-respirometer of the type described by Crisp and Thorpe[5]) was found to be 23·6 c.mm./gm./min.; after paralysis by contact with crystalline D.D.T. at 36° C. for two hours, it fell to 7·8 c.mm./gm./min. Changes in respiration-rate and the degrees of recovery from paralysis were compared after injection of sodium succinate, pyruvate, lactate and glucose into the blood of larvæ from the same batch of paralysed insects (dosage per insect, 0·15 c.c. 1 per cent solution in phosphate buffer, *p*H 7·4). Succinate induced complete, and glucose partial, recovery; lactate and pyruvate were ineffective. The uptakes of oxygen after injection were: succinate, 17·8; glucose, 11·2; pyruvate, 7·2; and lactate, 6·9 c.mm./gm./min.

Narcosis produced by injection of 0·4 per cent chloroform, 1·0 per cent ether, or 0·6 per cent amyl alcohol (0·15 c.c. aqueous solution) into the blood of mature larvæ was also antagonized by simultaneous injection of 1 per cent succinate; but not by glucose, lactate, or pyruvate. After succinate injection, adult blowflies became considerably more resistant to the narcotic action of these fat solvents applied internally by injection, or externally in vapour form. Flies treated externally with alumina and internally with succinate remained active in the presence of crystalline D.D.T. for several hours, showing clearly the combined influence of permeability and metabolic factors on D.D.T. activity.

These results show that the cuticle lipids play an important part in influencing the selective action of D.D.T. at the peripheral nervous system; but the action is primarily reversible and analogous to the narcotic actions of fat solvents, involving an interference with the utilization of succinate, an essential metabolite in oxidative metabolism. Succinate antagonism has also been observed with analogues of D.D.T., and with the structurally unrelated 'Gammexane' (γ-hexachloro*cyclo*hexane).

A full account of this work will appear elsewhere.

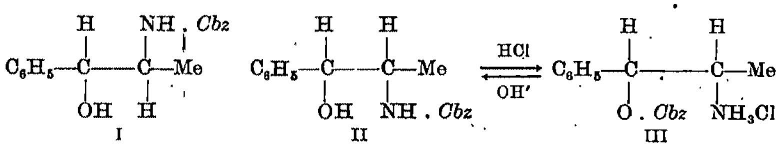
Separation of Diastereoisomeric Amino-Alcohols

The separation of diastereoisomeric amino-alcohols is of importance as they have very different pharmacological properties. Hitherto fractional crystallization has been used as the only suitable method for this purpose; however, sometimes, for example, in separating *nor*-ephedrine from *nor*-ψ-ephedrine[1], it proved to be unsatisfactory.

We have devised a new method of separation based on the different behaviour of diastereoisomeric N-acyl-amino alcohols towards alcoholic hydrogen chloride[2,3]. When a mixture of N-benzoyl-*dl-nor*-ephedrine and of N-benzoyl-*dl-nor*-ψ-ephedrine was treated with nearly the equimolar amount of this reactant, the former amide could be recovered unchanged, whereas the latter was quantitatively converted—due to an acyl shift N → O—into O-benzoyl-*dl-nor*-ψ-ephedrine hydrochloride. This water-soluble salt was easily separated from the insoluble amide in good yield. The same method also proved useful in separating amino-alcohols of other type; for example, N-benzoyl ephedrine and N-acetyl-1.2-diphenyl-amino-ethanol from their stereoisomers.



$$C_6H_5-\underset{OH}{\overset{H}{C}}-\underset{H}{\overset{NH\cdot Cbz}{C}}-Me \qquad C_6H_5-\underset{OH}{\overset{H}{C}}-\underset{NH\cdot Cbz}{\overset{H}{C}}-Me \underset{OH'}{\overset{HCl}{\rightleftharpoons}} C_6H_5-\underset{O\cdot Cbz}{\overset{H}{C}}-\underset{NH_3Cl}{\overset{H}{C}}-Me$$

I II III

$Cbz = C_6H_5\cdot CH_2OOC$—

However, the conversion of the separated acyl derivatives into the appropriate amino-alcohols by acid hydrolysis may sometimes effect Walden inversion[4]; on the other hand, alkaline deacylation could result in a cleavage to aldehydes[5]. To avoid this difficulty, we attempted the separation of N-carbobenzoxy derivatives of diastereoisomeric amino-alcohols with subsequent removal of the protecting group by hydrogenolysis, that is, under very mild conditions. We succeeded in separating N-carbobenzoxy-*dl-nor*-ephedrine (I, m.p. 103°) from N-carbobenzoxy-*dl-nor*-ψ-ephedrine (II, m.p. 83°) on converting the latter by acyl migration N → O into the water-soluble hydrochloride of O-carbobenzoxy-*dl-nor*-ψ-ephedrine (III, m.p. 229°); this furnished on alkalinization (owing to a reverse acyl migration O → N) the N-carbobenzoxy derivative (II, m.p. 83°). As expected, hydrogenolysis afforded from the separated carbobenzoxy derivative I the amino-alcohol *nor-dl*-ephedrine, from II *dl-nor*-ψ-ephedrine, with very good yields. This new method will be investigated with further types of amino-alcohols, and details will be published later.

This separation was made possible by the fact that in the molecule of the type of pseudo-ephedrine, more suitable steric conditions are available for acyl migration than in that of ephedrine. Obviously, the hypothesis of free rotation around the simple C—C linkage in this series of compounds[6] appears to be invalid[7].

This theoretical problem will be treated in detail elsewhere[8].

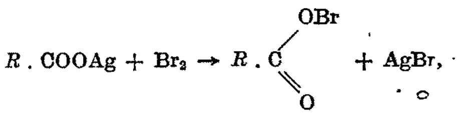
Reaction of Bromine with Silver (+)-α-Phenylpropionate: an Electrophilic Bimolecular Substitution

In a review of the literature of the reactions of the silver salts of carboxylic acids with bromine, Kleinberg[1] has concluded that when one equivalent of salt reacts with two of bromine, an intermediate compound *R*.COOBr is formed,



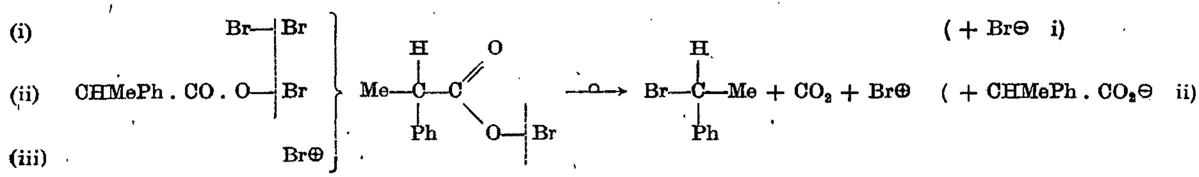
$$R\cdot COOAg + Br_2 \rightarrow R\cdot C\overset{OBr}{\underset{O}{\lessgtr}} + AgBr,$$

which decarboxylates to give the bromide *R*Br, and from the addition of *R*.COOBr to olefins and other reactions, that the bromine atom reacts as a 'positive' halogen.

In order to elucidate further the mechanism of the substitution of carboxyl by bromine, silver α-phenylpropionate, prepared from the acid having $\alpha_D^{15^\circ} + 42{\cdot}3^\circ$ (1, 0·5), optical purity 81·7 per cent, was allowed to react in boiling carbon tetrachloride with two equivalents of bromine; it gave, in good yield, α-phenylethyl bromide, $\alpha_D^{16^\circ} + 46{\cdot}2^\circ$ (1, 1·0), optical purity 35·2 per cent by comparison with the highest recorded rotation for this compound, $\alpha_D^{18^\circ}$ 131·4° (1, 1·0)[2].

The retention of asymmetry for this substitution is thus 43·1 per cent, and the following data permit comparison of the configurations of the acid and the bromide. (+)-α-Phenylpropionic acid has been converted with retention of configuration to (−)-α-phenylethylamine by the Hofmann and other rearrangements[3]. The (−)-amine with nitrous acid yields (+)-α-phenylethyl alcohol with considerable racemization[4]: it is considered that during this reaction the diazonium ion CHMePh.$N_2^{\oplus}$ dissociates into nitrogen and the ion CHMePh⊕, and that the latter reacts with water to form the alcohol with a preponderance of the inverted configuration, due to shielding of the original point of attachment by the released nitrogen molecule. Finally, (+)-α-phenylethyl alcohol and (+)-α-phenylethyl bromide have the same configuration[5]. Thus (+)-α-phenylpropionic acid and (+)-α-phenylethyl bromide have opposite configurations, and the silver salt – bromine reaction proceeds with inversion of configuration.

The following mechanism for the reaction is put forward: the molecule CHMePh.COOBr is first formed and then, by reaction with bromine (i), or with a second similar molecule (ii), the ion Br⊕ is formed in small concentration; thereafter reaction proceeds by (iii), a chain-reaction regenerating Br⊕:



The α-phenylethyl bromide formed by this mechanism would be fully inverted; the bromide obtained experimentally was inverted but partially racemized.

α-Phenylethyl bromide, $\alpha_D^{17^\circ}$ 96·6° (1, 1·0), was dissolved in carbon tetrachloride and heated under reflux for one hour with silver bromide and a small quantity of bromine; the α-phenylethyl bromide recovered from this solution had $\alpha_D^{18^\circ}$ 0·2° (1, 1·0). Racemization may have occurred either by bimolecular halogen exchange or by a radical reaction:

$$R\text{Br} + \text{Br}_2 \rightarrow R\cdot + \text{Br}_2 + \text{Br}\cdot \quad ; \quad R\cdot + \text{Br}\cdot \rightarrow R\text{Br}.$$

From this observation it is concluded that the bromide of the original experiment was racemized after its formation.

The silver salt – bromine reaction is a bimolecular substitution with inversion of configuration effected by electrophilic reagents, 'positive' bromine and bromine anion, and appears to be the first established example of this class of replacement reaction.

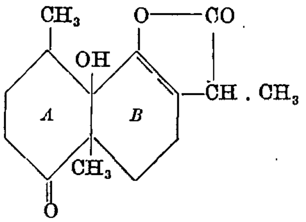
Desmotropo-ψ-Santonins

The butanolide structure proposed by Clemo and Cocker[1] for desmotropo-ψ-santonin (II) [p. 289], which is formed by the action of warm 55 per cent sulphuric acid on ψ-santonin, has been confirmed (compare Cocker and Lipman[2]). An intermediate compound in this transformation is now named ψ-santonic acid, to which structure (III) is tentatively assigned. Assuming that the most likely structure for ψ-santonin is (I), the conversion of this to (II) involves the destruction of asymmetry at C_1, C_5 and C_{10}. In addition, C_8 and C_9 will also be affected during the reduction of ring *B*, which probably takes place by bond migration. By the nature of the acidic reagent involved in the re-arrangement, it is most unlikely that the configuration of C_{11} will be affected. Hence the conversion of ψ-santonin to desmotropo-ψ-santonin should lead to two pairs of diastereoisomers in both of which the configuration of C_{11} should be the same. Two of the latter should have the *cis* configuration and the other two the *trans* configuration at C_8—C_9.

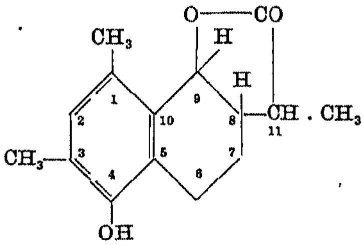
The conversion of ψ-santonin to desmotropo-ψ-santonin is now found to yield a mixture of desmotropo compounds. Crystallization of this mixture yields the desmotropo compound (m.p. 189°; $[\alpha]_D^{20^\circ} + 68^\circ$) already described, which we now name + β-desmotropo-ψ-santonin, in accordance with the nomenclature of Huang Minlon *et al.*[3], and a second desmotropo compound + α-*iso*-desmotropo-ψ-santonin, m.p. 251–253°; $[\alpha]_D^{20^\circ} + 68{\cdot}5^\circ$.

When + β-desmotropo-ψ-santonin is heated in boiling anhydrous xylene with anhydrous potassium carbonate, it gives + α-desmotropo-ψ-santonin (m.p. 171–172°; $[\alpha]_D^{20^\circ} + 153^\circ$). The new compound is probably produced by the inversion of C_{11} through the enol, and it is unlikely that C_8 and C_9 are affected. The lactone ring is, in fact, not opened.

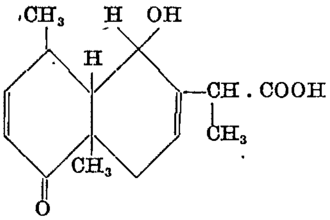
When + α-*iso*-desmotropo-ψ-santonin is treated in a similar manner or heated above its melting point, a fourth dextrorotatory desmotropo compound, + β-*iso*-desmotropo-ψ-santonin (m.p. 268–270°; $[\alpha]_D^{20^\circ} + 165^\circ$) is obtained.



(I)



(II)



(III)

We have thus obtained the four possible dextro forms. So far, attempts to invert C_8 and C_9 by acidic reagents have either yielded unchanged compounds or intractable mixtures; but further work on this point is in progress.

The work described forms part of a much wider investigation on the structure of ψ-santonin, the results of which will shortly be submitted for publication elsewhere.

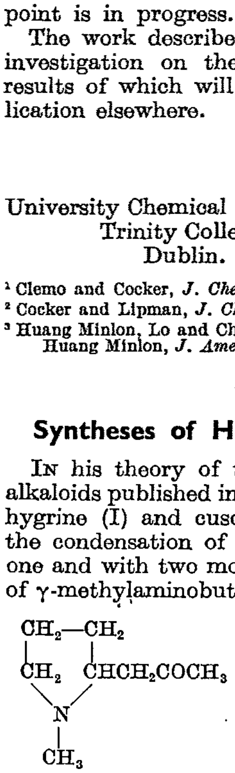
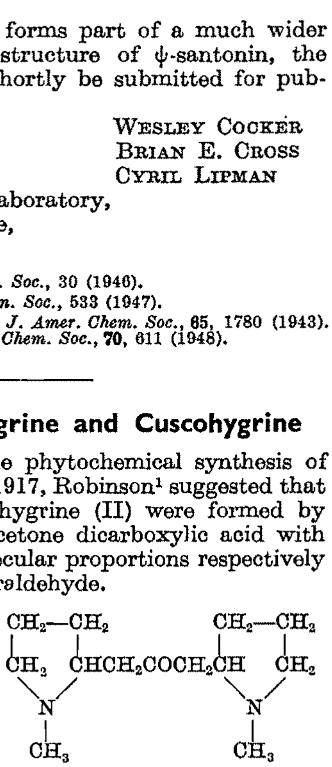
Syntheses of Hygrine and Cuscohygrine

In his theory of the phytochemical synthesis of alkaloids published in 1917, Robinson[1] suggested that hygrine (I) and cuscohygrine (II) were formed by the condensation of acetone dicarboxylic acid with one and with two molecular proportions respectively of γ-methylaminobutyraldehyde.



(I)



(II)

Robinson's theory became widely known and is frequently stated in text-books; but no attempt to carry out these reactions seems to have been made for nearly twenty years. Then in 1936 he[2] announced that "a synthesis of *dl*-hygrine on these lines has proved feasible", but so far as we are aware no account of this synthesis has appeared. Later, Schöpf[3] reported that he was unable to obtain *nor*hygrine from γ-aminobutyraldehyde and acetoacetic acid, although the phenyl analogue of this base was formed from the same aldehyde and benzoylacetic acid.

We have now found that acetone dicarboxylic acid condenses smoothly with two molecular proportions of γ-methylaminobutyraldehyde at *p*H 7 to produce cuscohygrine in excellent yield. The identification of the product was made by direct comparison of several of its derivatives with authentic specimens and by the agreement of the analytical figures with the calculated values. Similarly, we have obtained from the reaction between excess acetoacetic acid and γ-methylaminobutyraldehyde a base which we believe to be *dl*-hygrine. The physical constants of the base and its derivatives agree with the values recorded in the literature, and the analytical figures also accord with the calculated values. Although we have not yet had the opportunity of making direct comparisons with authentic specimens, there can be little doubt that the synthetic product is *dl*-hygrine.

Full details of this work, including a discussion of the stereochemistry of cuscohygrine, will be published shortly.

We are greatly indebted to Prof. R. L. Shriner of the State University of Iowa for the provision of a sample of authentic cuscohygrine.

I would like to congratulate the authors on these syntheses, which are fundamental for the theory. My own synthesis, mentioned in 1936, employed acetonedicarboxylic acid in excess, but was otherwise identical. Though the product was undoubtedly *dl*-hygrine, the opportunity to add the final touches necessary for publication did not occur.

It is very satisfactory that this synthesis will now be placed on record and will become available for reference.

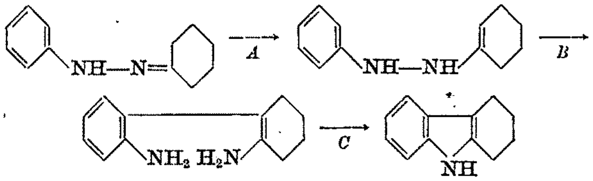
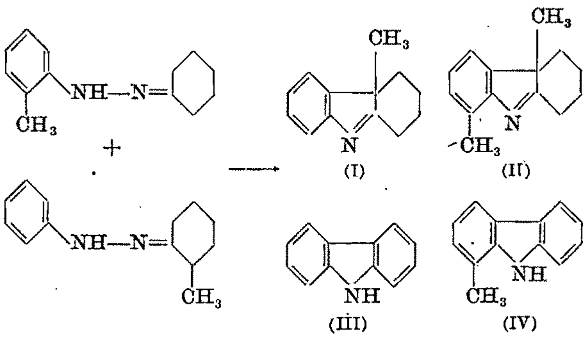
Mechanism of the Fischer Indole Synthesis

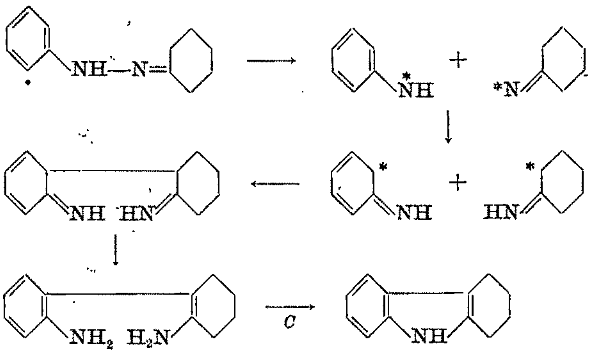
The mechanism previously proposed[1,2] for the Fischer indole reaction has assumed that the intermediate stages involve an *o*-benzidine-type re-arrangement. This may be illustrated as follows, considering, as an example, the phenyl hydrazone of *cyclo*hexanone:



Ingold[3] has clearly shown that the benzidine rearrangement is intramolecular in nature, but it has now been found that the Fischer indole synthesis proceeds by an intermolecular reaction. This fact was proved by studying the cyclization of a mixture of equal weights of the *o*-tolyl hydrazone of *cyclo*hexanone and the phenyl hydrazone of 2-methyl *cyclo*hexanone in boiling glacial acetic acid solution. The basic products formed in this reaction were 11-methyl- (I) and 8 : 11-dimethyltetrahydrocarbazolenine (II), and the neutral products gave, after dehydrogenation, carbazole (III) and 1-methyl carbazole (IV). These four products were formed in practically equivalent proportions.



Thus it is apparent that fission of the N—N linkage has taken place and that an intermolecular reaction is involved. The full implications of these results, and the importance of certain by-products from *o*-halo-substituted phenylhydrazones of *cyclo*hexanone[4], will be discussed in detail elsewhere. The provisional mechanism proposed may be formulated as shown :



Alternatively, stage *A* (see above) may occur initially, but, in either case, the same intermediate is formed as that resulting from stage *B* (an *o*-benzidine re-arrangement).

The validity of this free radical mechanism, as opposed to an ionic mechanism, is being tested by kinetic evidence.

Polarography with Slowly Forming Mercury Drops

BY means of a capillary greatly restricted in the stem but with an orifice radius of 108 μ, it has been found possible to study current – time and current – voltage curves for single mercury drops with ordinary polarographic equipment—a Cambridge polarograph with photographic recording. Drop-times in a given solution could be varied between 16 sec. and 8 min. and were reproducible. The drop-weight in $0 \cdot 1\,N$ potassium chloride was about 28 mgm. The results show the change in character of current – time curves at constant voltage as the voltage is altered, give accurately measurable values for current – time relations during cathodic reduction, and indicate a new use for the polarograph in quantitative analysis by reason of the appearance of non-suppressible maxima on current – voltage curves.

The current – time curves of growing drops with no reducible matter present show that the current gradually rises when the applied potential is positive to that of the electrocapillary maximum, but that it gradually decreases when the potential is more negative, the falling-off of a drop being accompanied by a sudden downward jump of current in the first case and a sudden upward jump in the second. With sodium sulphite and zinc sulphate in oxygen-free potassium chloride solution, current – time curves at successively increasing negative potentials (*vs.* saturated calomel electrode) show that inversions of shape occur between $-0 \cdot 1$ and $-0 \cdot 2$ V., $-0 \cdot 4$ and $-0 \cdot 6$ V. (at the electrocapillary maximum), and $-0 \cdot 9$ and $-1 \cdot 1$ V. (deposition of zinc); for example, the current decreases with drop growth at $-0 \cdot 1$ and $-0 \cdot 7$ V., and increases with drop-growth at $-0 \cdot 3$ V. and $-1 \cdot 2$ V. The occurrence of such effects, which are also observable with normal capillaries (drop times 2–7 sec.), should have, *inter alia*, some bearing on the method of measuring wave-heights, but a study of numerous papers has failed to reveal that workers realize their existence.

Current – time curves for reductions at constant applied potential approximate closely to ordinary parabolas, $i \propto t^{1/2}$. This fact conflicts with conclusions derived from the Ilkovic equation ($i \propto t^{1/6}$), but it accords qualitatively with Steghart's findings[1] in the case of a rapid-dropping capillary studied by means of a high-speed, high-precision recorder.

Current – voltage curves during the life-time of a single drop over the range corresponding to a reduction show a current-peak in place of the initial part of the usual flat diffusion-current portion of the polarographic curve. The peak is not a polarographic 'maximum' since it is not removable by a maximum suppressor and the peak currents do not appear with drops taken at constant potential. With a given solution, the peak-height increases with the size attained by the drop at the potential of the peak, and is linearly related to the volume and not the surface area of the drop. The maximal values of the peaks obtained at various drop-rates are identical. The peak potential is independent of the size of the drop at the peak when the rate of flow of mercury is kept constant, but it becomes more negative as the rate of flow is increased.

If the potential rise is started at the same size of drop-growth in solutions containing various amounts of reducible matter, the peak height is proportional to the concentration. The records obtained, for example, with Cd•• and Zn••, are smooth steep curves rising to well-defined peaks, the heights of which can be measured with much greater certainty than ordinary step-heights.

With special equipment for very rapid application of potential and oscillographic recording, Matheson and Nichols[2] and, later, Randles[3], found peaks on current – voltage curves obtained with normal capillaries. The present results are given by the usual slow rate of application of potential, and no special equipment other than the capillary is required. The investigation is being continued and details will be given elsewhere.

This note is published by permission of the Ministry of Supply and the Controller of H.M. Stationery Office.

Mercury Photosensitized Reaction of Tetrafluoroethylene

I have found that the irradiation of tetrafluoroethylene in the presence of mercury vapour by light of wave-length 2536 A. causes a mercury photosensitized reaction. The pressure falls and a white powder is formed. A gas of molecular weight 150 ± 1, b.p. – 33° C., m.p. – 80° C., believed to be hexafluoro*cyclo*propane, molecular weight 150, b.p. – 31° C.[1], and a small quantity of a mixture of compounds with higher boiling points have been isolated from the products of the reaction. The white powder has properties similar to those of polytetrafluoroethylene $(CF_2)_n$ [2], the product of the catalysed polymerization of tetrafluoroethylene.

The quantum efficiency of the reaction at various pressures has been measured. At pressures below 10 cm. of mercury, quenching of the mercury fluorescence is not complete, and only very approximate calculations of quantum efficiency can be made. Some of the quantum efficiencies obtained are given in the accompanying table.

Temperature (° C.)	Initial pressure (cm. mercury)	Light absorbed (quanta/hr. × 10^{-18})	$\eta_{C_3F_6}$	φ_P
29·8	10·43	1·33	0·03	0·18
29·8	33·61	1·38	0·32	0·30
29·8	8·01	91	0·017	0·02
29·8	35·03	104	0·07	0·12

$$\eta_{C_3F_6} = \frac{\text{molecules } C_3F_6 \text{ formed}}{2 \times \text{quanta absorbed}}; \quad \varphi_P = \frac{\text{molecules } C_2F_4 \text{ polymerized}}{\text{quanta absorbed}}$$

The quantum efficiency of hexafluoro*cyclo*propane production increases with increasing pressure and decreases with increasing intensity. As this compound is the main product, one of the primary reactions must involve the breaking of a carbon–carbon bond. The formation of a polymer indicates the presence of free radicals in the system, and the decrease of efficiency of perfluoro*cyclo*propane production with increasing intensity can be accounted for only by a radical recombination reaction. The results obtained are in accord with the following reaction scheme.

$$\begin{aligned} C_2F_4 + Hg(^3P_1) &= 2CF_2 + Hg(^1S_0); && (1)\\ CF_2 + C_2F_4 &= C_3F_6; && (2)\\ 2CF_2 + C_2F_4 &= 2C_2F_4; && (3)\\ CF_2 + CF_2 &= C_2F_4 \text{ (at the walls).} && (4) \end{aligned}$$

Reaction (2) is probably the reaction initiating polymer formation.

A surprising feature of the reaction is that the 112 k.cal. per gm. mol. available from the excited mercury atoms is sufficient to cause the carbon–carbon bond to break. The bond-energy of the double bond in ethylene is stated to be 153 k.cal. per gm. mol.[3] If the double bond in tetrafluoroethylene has about the same bond-energy, reaction (1) can take place only if the bond-energy of the carbon–fluorine bond in the difluoro-methylene radical is approximately 10 k.cal. higher than the corresponding bond-energy in tetrafluoroethylene. The reaction of tetrafluoroethylene may be contrasted with the mercury-photosensitized reaction of ethylene, in which acetylene and hydrogen are the primary products[4].

An Outline of a Theory of Detonators

Further to the reported property of silver formate of detonating at 85–90° [1], it is perhaps opportune to offer some commentary on the nature of detonators in general. They are commonly derived from acids, the anions of which are the repositories of considerable stores of energy. This is liberated when the anions are discharged and the radicals, thus initially produced, decompose. Anodic discharge from aqueous solution is obviously one method of achieving this, and Audubert has recorded that such discharge of the azide ion is accompanied by liberation of light energy[2]. Another mode of discharge, illustrative of the possible application of these ideas to the picrates, is represented by the action of lead tetracetate on various *para*nitrophenoxide ions, leading to their decomposition into nitric oxide and *para*quinone[3]. In detonators, such anions are associated with heavy metallic cations in what may be approximately described as covalent union[4], and this constitutes a stage in the transition from the fully charged anion to the unstable radical. The process of transition is completed by a suitable supply of energy in the form of a blow, heat or otherwise, and this stage is illustrated by the historic thermal decompositions of mercuric oxide and cyanide and by that of silver salts of carboxylic acids. Local decomposition of this kind in a mass of the detonator will liberate energy, which on communication to immediately adjoining material will cause further decomposition leading to detonation.

Regarding individual detonators, the fulminate ion (CNO)′, derives its energy from the abnormal arrangement of its atoms, as is clear from the fact that oxidation of cyanide ion yields cyanate ion (OCN)′. The fulminate ion, like the azide, formate and picrate ions, is stabilized by resonance; but the double negative charge by itself accounts for the existence of the acetylide ion[5].

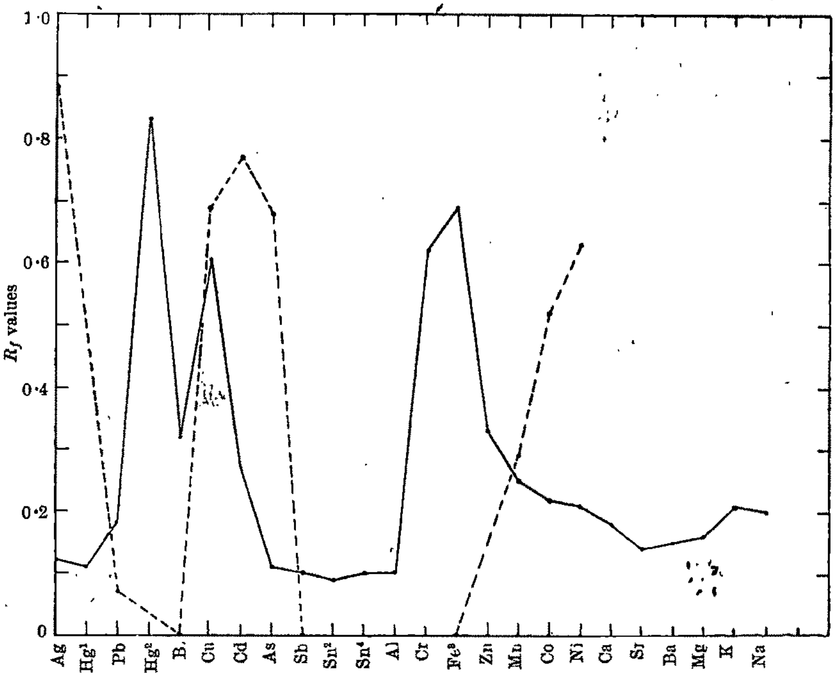
Inorganic Paper Chromatography and Detection of Cations by Fluorescence

The importance and potentialities of the paper chromatographic separation of inorganic cations have already been indicated by recent communications of Linstead[1] and Lederer[2]. In this laboratory we have been working along similar lines, but with the object of finding general methods of separation and identification, rather than specific methods for two or three ions. Such a scheme has obvious advantages in qualitative analysis.

Our technique is essentially that already described for organic substances by Martin and Synge[3], using Whatman No. 1 filter paper; drops sufficient to give spots of ½ cm. in diameter being placed 4 cm. apart. The solutions were usually approximately $N/10$ in acetic acid. In this way, tests for at least twenty-four cations at a time can be performed and compared with the unknown.



Full line, butanol mixture; broken line, collidine mixture

A variety of solvents has been tried, and the relative R_f values, determined under the conditions of our experiments for two promising solvents, namely: *Solvent* 1, 50 per cent butanol, 10 per cent acetic acid, 5 per cent acetoacetic ester, 35 per cent water; *Solvent* 2, 50 per cent collidine fraction, 50 per cent water, are shown in the accompanying graph. This clearly illustrates the separations possible, and it will be seen that the differential effects of two solvents open up the possibility of two-way separations.

The location of the cations on the paper can be revealed by hydrogen sulphide in some cases; but we have found the use of fluorescence a very marked advantage, since with suitable spraying reagents we can detect nearly all the cations of the ordinary qualitative tables. Our procedure is to spray the dry paper with the selected reagent, allow it to dry and then examine it under the ultra-violet lamp; some of the spots fluoresce and others appear dark through quenching of the fluorescence. From a large number of trials, the following reagents proved most successful: kojic acid, *o*-aminobenzoic acid, morin, 1-naphthylamine-8-sulphonic acid, 2-naphthylamine-1-sulphonic acid. (*Note added in proof.* 8-hydroxyquinoline is extremely useful as a fluorescent reagent.) An interesting effect was noticed, particularly for kojic acid, on subsequent treatment of the paper with ammonia gas; this causes some dark spots to fluoresce (for example, Hg^{++}), quenches the fluorescence of others (for example, Mg^{++}), and makes others quite invisible (for example, As^{+++}). This was used to distinguish between various cations.

The mechanism involved in the separation seems to be essentially partition chromatography for the butanol mixtures, since water alone washes the ions down the paper, while butanol with 10 per cent glacial acetic acid produces almost no movement. Small quantities of acetoacetic ester or glycerol in the butanol mixture tend to concentrate the spots and prevent tailing. For solvents such as collidine, complex formation and adsorption probably have the dominant roles.

Drinking Spouts for Laboratory Animals

Laboratory rats are usually allowed to obtain their water from an inverted glass bulb with a stem, or from an inverted bottle fitted with a bung and spout. The bulbs are awkward to clean and refill, and are very easily broken. The bottles are satisfactory: but the bungs and spouts jam and break, with frequent minor casualties to attendants. The extension of watering to mice, rabbits, guinea pigs, etc., necessitated by the use of diets in the form of dry pellets and cubes (Bruce and Parkes[1,2]), made urgent the elaboration of a more efficient water container.

We have therefore evolved a drinking spout which can be attached to the cap of almost any standard screw-topped bottle. The spout is made from ⅜-in. external diameter 18-gauge metal tubing. The distal end is rounded by spinning to form a vent about ⅛-in. diameter. The proximal end is threaded for about half an inch, and a thin hexagon nut is screwed on up to the end of the thread. The end of the tube is then passed through a ⅜-in. hole pressed in the bottle top and secured by a second nut inside the cap. Both nuts are coated with 'Bostic' to ensure an air-tight joint. A washer inside the cap ensures an air-tight joint with the bottle. Spouts of this type can be made of any appropriate length and shape.

Two types are now in routine use at the National Institute for Medical Research. The first is 6 in. in length with a slight bend, and is attached to the aluminium cap of the standard blood transfusion bottle for use with large cages (for example, rabbit cages), or to the cap of the standard 10-oz. flat bottle for use with smaller cages. The bend in the spout enables it to be used in the horizontal position on top of the cage or in the vertical position on the outside of the cage, to which it is attached by means of a wire holder. Where the cap of the bottle is large, as with the blood transfusion type, it should be strengthened with an 18-gauge disk inside each nut. The second type of spout is short (2 in.) and straight, and is used on the plastic cap of a small squat bottle (ink bottle type) for rat isolation cages or mouse boxes. The spouts can be moved from one type of bottle cap to another as required. The present spouts are made of 'Dural' tubing, and the price is very moderate. The short spout and squat bottle together cost about 25 per cent of the present price of the fragile glass bulb which they replace completely. It is likely, however, that the 'Dural' tubing will prove too soft for use with guinea pigs, and that brass spouts will be required for this species.

We are indebted to Dr. B. Wheeler Robinson for suggestions on design. The equipment described was made by Herbert W. Baker (Engineering), Ltd., St. John's Works, 2a Kilburn Lane, London, W.10.

Science in the East African Groundnut Scheme

SIR JOHN RUSSELL, stressing, in his address to the le Play Society at Oxford on December 31, the importance of adequate preparatory experimental work before developments such as the groundnut scheme are undertaken, is reported (*The Times*, January 1) as having said that the scientific and technical staff of the scheme "never really had a chance to do their work properly" and that they were "not allowed the necessary time" to make small-scale experiments to discover "the snags and difficulties of the scheme. He is also said to have stated that "those who had been experimenting" in the scheme "were very disappointed with the results".

These reports may give rise to impressions other than those intended by Sir John Russell, and on two points in particular clarification is necessary.

First, it is true that the scheme was started in advance of any detailed experimental work in the areas concerned. This course was dictated by the urgency of the world food position, since it was believed on the technical information and experience available in 1946 that the general conditions were adequate for the economic production of groundnuts and other crops in the areas designated.

This proposition has from the first been under test. I was a member of the advance party which reached Tanganyika early in February 1947, and the scheme's Scientific Department, which now includes seventeen European scientific and technical workers, together with a growing corps of African scientific assistants, has carried out a considerable programme of soil and vegetation surveys, followed by laboratory and field studies of soil fertility, alternate cropping and rotations, and plant protection problems.

Three experiment stations, each of several hundred acres, have been developed in the central, western and southern provinces of Tanganyika. The headquarters, at Kongwa, include a tented laboratory, a library and a statistical section. These studies have done much to confirm the conclusions of the Wakefield mission on agricultural questions, at least so far as Tanganyika is concerned.

It is true, of course, that the scientific and technical effort will need considerable expansion if the problems of establishing, in a matter of ten years or so, a system of large-scale mechanized agriculture over millions of acres of new land in East Africa are to be dealt with adequately. The need is particularly acute in respect of laboratories. We meet, inevitably, many difficulties of supplies and communications; but we have been well supported by the management of the scheme, whether under the United Africa Company or the Overseas Food Corporation.

Secondly, the many delays and difficulties of the last two years, which are as disappointing to the technical staff as to all other workers on the project, are not in the main due to lack of technical information such as agricultural research can be expected to provide, nor, as has been alleged by some, to disastrous failures on the agricultural side. They arise in great part from engineering problems of clearing, construction, communications and general development, which have proved to be greater than was foreseen, and could not have been eliminated by small-scale research, since they are essentially problems of large-scale operation and organisation in new country. These very delays give us on the research side the more time to press forward our investigations.

This is not to say that the agricultural problems are negligible. They are many and important; some promise to give much trouble. Nevertheless the scientific and technical staff share with Sir John Russell, under whom many of us formerly served, the belief that we shall find the solutions.

A. H. BUNTING

APPLICATIONS OF ELECTRONICS TO RESEARCH AND INDUSTRY

THE first Electronics Symposium of the Scientific Instrument Manufacturers' Association was held in the Caxton Hall, Westminster, during November 18–19. Mr. A. G. D. West, chairman of the Electronics Group of the Association, presided at the first session, and the proceedings were opened by Sir Edward Appleton, who expressed his belief in the great existing and potential importance of electronic techniques in industrial processes. He gave instances in which the introduction of such devices had secured savings of time and money out of all proportion to their cost. The Department of Scientific and Industrial Research had set up a small organisation to explore the field of potential application in industry and to advise on the design and supply of electronic equipments appropriate to the various particular problems they encountered.

The first paper in the symposium itself was by D. J. Mynall (British Thomson-Houston Co., Ltd.) on "Electronics in Computing". Present developments in automatic electronic computing machines can be classified as digital or analogic, according to whether they operate on numbers or on continuously variable quantities. The digital type, with its capacious 'memory' based on supersonic delay lines, cathode ray, or magnetic devices, has a very wide range of application, very great speed, and can give any desired accuracy; but its construction is correspondingly complex. Analogue computors, on the other hand, though generally simpler in construction, are inherently limited in accuracy. It was pointed out in the discussion that the larger types of electronic digital computor will open up new fields of pure and applied science, since they will, for the first time, make practicable the solution of problems which would otherwise need a prohibitive time for computation.

In the second paper, entitled "A Review of Frequency Measurement", by E. A. Rea Palmer and R. W. Darvill (Marconi Instruments, Ltd.), the relation between frequency, time and wave-length was discussed, and the customary division of the electromagnetic wave spectrum into bands was considered. Reasons were given for treating frequency measurement on a functional basis, the chief among them being that different accuracies are required in the various fields, which range from power engineering to ultra-high-frequency radio communications. Equipment can be divided into two groups: direct indicators with an accuracy not better than one part in 10^4; and comparison instruments in which the reference standard has a constancy better than one part in 10^7. The types of instruments appropriate to the various fields were enumerated, and some typical models were described and demonstrated. These included an 'electronic' meter of the limiter-counter type, for use at low frequencies, a high-precision comparison instrument for medium frequencies, a frequency synthesizer for high frequencies, tuned lines for very high frequencies and a crystal calibrator for the ultra-high-frequency band.

The first morning session concluded with a paper on "The Measurement of Small Displacements by Electrical and Electronic Means", in which R. E. Reason (Taylor, Taylor and Hobson, Ltd.) explained that transducers of high stiffness, such as piezoelectric crystals, are suitable for measuring force, while transducers of low stiffness, such as photoelectric or electromagnetic devices, are more appropriate for measuring position.

It was pointed out that electronic instruments, although capable of high magnification, are often unsuitable for workshop applications, where the requirements of low magnification, robustness and cheapness are more easily met by simpler electrical devices. On the other hand, certain types of application such as, for example, the measurement of surface finish, require electronic devices, since high magnification with very low stiffness is necessary. Some practical applications of electronic methods were illustrated by reference to various historical and commercial instruments.

Dr. A. J. Maddock took the chair for the afternoon session, which was opened by G. Syke (Baldwin Instrument Co., Ltd.) with a paper on the "Measurement of Ionizing Radiations". He described the operation of an ionization gauge comprising an ionization chamber, a capacitance or resistance, and a potential measuring device, the voltage across the capacitance or resistance being a measure of the dose or dose-rate respectively. Mr. Syke emphasized the advantages of negative feedback circuits in association with electrometer valves, and described several such circuits. Other instruments mentioned were those using vibrating reed electrometers, multiplier photocells, and Geiger–Müller tubes, the last-named being very suitable for detecting traces of radioactive materials. The principle of operation of the tube and its use with electronic pulse counters were described.

In the second paper, by W. Steckelmacher (W. Edwards and Co. (London), Ltd.), on "High-Vacuum Gauges", reference was made to instruments for measuring low gas pressures both in the research laboratory and in industry. For pressures down to 10^{-4} mm. of mercury, the Pirani gauge is valuable and may be used in a Wheatstone bridge network; alternative schemes making use of a thermocouple welded to the filament are available. The cold-cathode glow-discharge tube can be used in the range 5×10^{-3} to 10^{-5} mm. of mercury, an extension of the range to the low value quoted having been realized by the use of a magnetic field and a special electrode array which increases the opportunities for collision and thus augments ionization. Hot-cathode ionization gauges are effective at pressures down to 10^{-8} mm. of mercury under ideal conditions. They are similar in construction to ordinary triodes, but are used with the grid at a positive potential of about 100 volts and the anode at a negative potential of about 20 volts. For the most accurate measurement of very low pressures, the Knudsen gauge, which uses the direct principle of molecular momentum transfer, is recommended.

The McLeod gauge still remains the standard instrument, and may be used for pressures down to 10^{-4} mm. of mercury. The other types of gauges are calibrated by reference to the McLeod gauge, it being necessary at the lower pressure ranges to extrapolate readings. The indications of the McLeod gauge are subject to error when the system contains vapours.

One of the serious difficulties in the use of the ionization type of gauge is the reaction of the gauge on the system. In some cases the pressure in the vicinity of the gauge may be appreciably lower, in others appreciably higher, than the pressure in the rest of the system, depending on whether the gauge is producing gas or 'gettering'. The author indicated a possible error factor of 10, and concluded his paper with the statement that much work remains to be done to eliminate the difficulties at present confronting the accurate measurement of very low pressures.

In the next paper, on "The Radiosonde and its Applications", J. Foster Veevers (Salford Electrical Instruments, Ltd.) gave details of the processes and test procedures now adopted in the large-scale manufacture of the standard British instrument known as the Kew Mark II. This equipment, originally developed at the National Physical Laboratory and later modified by the Meteorological Office, is now in daily use for the collection of upper air data. To obtain a temperature accuracy of ± 1° F., a pressure accuracy of ± 5 millibars and a humidity accuracy of 10 per cent, great care has to be taken in the routine calibration of the instruments, and various special chambers have been constructed for this purpose.

On the second day of the meeting, emphasis was given to industrial applications of electronics, the chairman at this session being Mr. F. A. Downes.

In the first paper, on "Some Industrial Applications of Ultrasonics", D. O. Sproule (Henry Hughes and Son, Ltd.) pointed out that although a vast number of applications have been indicated in the literature, relatively few have so far resulted in devices of commercial value. The marine echo sounder was described and demonstrated, and extensions of its principle for industrial purposes were discussed, with particular reference to the location of flaws and the determination of the elastic constants of materials. The technique of non-destructive flaw detection was demonstrated, and the deduction of the elastic constants of a material from measurements of the velocity of propagation of both longitudinal and transverse vibrations was described. The process of grain refinement was outlined as a typical example of an application in which the objective is a permanent modification of the medium.

In the second paper, by G. S. Elphick, S. Y. Logan and A. R. Woods (Cinema Television, Ltd.), entitled "Metal Detection in Industry", an outline was given of the development of metal detection technique, from the war-time requirements of mine- and bomb-location to the latest industrial equipments currently in use. After summarizing present-day requirements, three detectors were described and the principles involved in their design were explained.

The first is a general-purpose detector of the regenerative type, for use in saw mills for locating metal in timber. The second is a variation of the first, and has been designed for pipe- and cable-location; while the third is a fully automatic industrial equipment in which frequency drift is automatically corrected. In this last instrument ferrous particles about $\frac{1}{16}$ in. in diameter or non-ferrous particles $\frac{1}{10}$ in. in diameter can be detected in materials travelling along a conveyor belt. This apparatus is finding increasing use in a wide range of industries as an inspection device, affording continuous protection for valuable plant, and an effective safeguard against the inclusion of metal in foodstuffs, pharmaceutical products, etc.

Introducing the third paper, on "Sound and Vibration Measurement in Industry", L. P. Corte (Dawe Instruments, Ltd.) stressed the increasing importance of noise control in industry, the first step towards which was the measurement of noise and vibration. He distinguished between the objective characteristics of noise, such as total intensity and the distribution of intensity with frequency, and the subjective characteristics such as loudness, pitch and annoyance. A range of instruments for objective measurements was described. A sound-level meter utilizing a piezo-electric microphone in conjunction with an amplifier and rectifier to measure the total intensity was described. In this instrument some account is taken of the characteristics of hearing, since the resistivity to low frequencies can be reduced at low intensity-levels in accordance with that of the ear.

A vibration meter was next described in which a piezo-electric pick-up is employed, of which the response is proportional to acceleration. A description was then given of an analyser which could be used with either the sound-level meter or the vibration meter. Finally, for the production of permanent records, a level recorder of the Neumann type was described, which gives a record on waxed paper on a decibel scale. A demonstration of the reproduction of the noises of trains, trams, etc., was much appreciated.

The chairman for the afternoon session was Mr. F. D. Hart, and a paper on "Electronics in Spectroscopy" was read by F. Holmes (Hilger and Watts, Ltd.). The development of direct-reading methods of spectrochemical analysis was outlined under the main headings of photocells, photomultiplier tubes, and thermopiles.

In Great Britain the lack of generally available photomultiplier tubes has caused attention to be directed to cæsium-type photocells; whereas in the United States complex and costly direct-reading spectrographs, based on photomultipliers, have been marketed. It is hoped that the supply position will be remedied by British manufacturers in the near future, although it still remains to be proved that the fundamental properties of this equipment offer any increase in accuracy over photographic recording for quantitative spectrographic analysis, and the advantage of speed of response may be illusory in view of rapid and localized fluctuations at the source.

For work in the infra-red region, a high-speed thermopile was described with a 90 per cent response within 15 milliseconds and an output of 50 microvolts per microwatt. A diagrammatic circuit of a direct-reading infra-red spectrometer based on this thermopile and a cathode ray tube was shown, and a separation of eight wave numbers at 10μ was claimed.

The lack of suitable ratio recorders was emphasized as a drawback to the double-beam system, and an outline of a suitable phase-sensitive recorder shown.

The final contribution to the symposium was by J. Bell (Muirhead and Co., Ltd.), who described "Some Developments in Picture Telegraphy". This paper, which was concerned entirely with the British equipment manufactured since the end of the War, has already been referred to in *Nature* of January 22, p. 145. At the symposium Messrs. Muirhead and Co. exhibited fixed and portable equipments, together with samples of pictures actually transmitted over telephone lines.

DUST IN INDUSTRY

CONFERENCE AT LEEDS

ABOUT two hundred delegates attended the Conference on "Dust in Industry" which was organised by the Society of Chemical Industry and held at the University of Leeds during September 28–30. The papers presented during the five sessions of the Conference covered a wide range of subjects and showed how dust problems enter into almost every major industrial process.

After a civic welcome by the Lord Mayor of Leeds, the delegates proceeded to the business of the first session under the chairmanship of Prof. H. V. A. Briscoe. Under the general title of "The Physical Characteristics and Estimation of Dust" the following four papers were presented: "Problems on the Design of Plant Handling or Producing Dust", by G. Nonhebel "A Rapid Method of Dust Estimation in Iron and Steel Foundries", by B. W. Lawrie; "Dust Hazards in the Explosives Industry", by Prof. W. M. Cumming, Dr. F. Rumford and Dr. W. G. D. Wright; and, finally, "Particulate Clouds in the Gas Industry", by E. H. M. Badger.

Mr. Nonhebel made a broad survey of the processes in the production or control of fine particles. From his review of the factors concerned in such operations as grinding and classification, the separation of dusts from gases and liquids, mixing, aggregation and the size analysis of dust samples he pointed out the lack of knowledge in this field and the vast amount of fundamental work which is needed before the design of plant for such purposes can be established on a sound scientific basis.

Mr. Lawrie described a quick method of dust estimation suitable for survey work in iron or steel foundries or other industries where the dust concentrations encountered are so great that counting of samples taken by the thermal precipitator is frequently impossible. In brief, samples collected by the thermal precipitator or by the Owens jet counter are photographed on a projection microscope and compared visually with a standard scale of dust concentrations. While admittedly this method gives only an estimate of the dust concentration, it is claimed that it is entirely adequate for comparing the efficiency of dust control systems and that it gives as good an indication as may be obtained of the health risk in an industry. This work has shown, incidentally, that more accurate estimates of thermal precipitator slides can probably be made by counting a photographic record rather than by the usual direct visual count.

Prof. Cumming discussed the three main dangers of excessive dust concentrations in explosives factories—ignition, health hazards from contact or by inhalation of the dust, and dermatitis. Trinitrotoluene and tetryl show all these three dangers to a greater or lesser extent. He described a simple photo-electric method used for measuring the relative 'dustiness' of explosives, and also gave an account of colorimetric methods devised for estimating the concentration of airborne dinitrotoluene, trinitrotoluene and tetryl sampled by the standard D.S.I.R. pump. Trinitrotoluene and tetryl are absorbed in a mixed solvent of methyl ethyl ketone and *cyclo*hexanone containing a little potassium hydroxide, and estimated by comparison with standard colour disks.

Mr. Badger described how, in the separation of dust from producer-gas, trouble was experienced with the formation of stalactitic growths across the electrostatic precipitator plates. The difficulty has been overcome by the evaporation of a small amount of tar oil into the gas. This condenses and forms a liquid film around the dust particles, rendering the deposit fluid enough to run off the plates. Removal of much tar fog from gas takes place in the exhausters; but particles of above a certain critical size only are removed. The tendency for spontaneous condensation, producing small droplets, can be minimized by mixing pre-cooled gas with the main gas stream, thus introducing nuclei for condensation. A portable electrostatic precipitator used during this work was described.

The discussion centred around Mr. Lawrie's paper. The chief criticism of his method was that it does not differentiate chemically between the particles present in foundry dusts. The health hazard is primarily dependent on the silica content and not on the total dust count. The suggestion that it is a quick method suitable for use in dust surveys was endorsed by several speakers.

The second and third sessions, under the chairmanship of Dr. Julian M. Leonard and Mr. A. V. Hussey, were both devoted to "Practical Aspects of the Dust Problem". The four papers given during the second session were "Some Methods of Reducing Contact with Dusts in Chemical Manufacture", by L. Marsden, G. W. Robertson and Dr. R. A. Storey; "The Problem of Dust in the Chemical Industry", by G. Lowrie Fairs and E. Godfrey; "The Problem of Dust in the Cotton Industry", by Dr. D. W. Hill; and "Some Practical Methods of Industrial and Atmospheric Dust Elimination", by J. H. Hellyer and J. Cleeve.

Dr. Storey considered means of preventing the formation of, and removing, air-borne dust at its origin in a variety of unit operations involving the charging, processing and discharging of dry materials. He suggested that dealing with the problem in this way is preferable to applying individual protection for each operator.

Mr. Lowrie Fairs divided dust problems into three types and suggested means of dealing with each of them: (*a*) where dust produced at one stage may interfere with later stages in a process; (*b*) where escape of dust causes atmospheric nuisance; and (*c*) where atmospheric dust entering a plant may cause contamination of a product. The possibility of obtaining large flows of sterile air by filtration through 'Stillite' blocks was mentioned.

Dr. Hill reviewed the causes of dust production in the cotton industry and the problems arising therefrom. Operatives are liable to suffer from a respiratory disease known as byssinosis after long exposure to the dust liberated during the opening and carding operations. Little is known about the active agent in the dust, but it is evidently to be found in the finer fractions and may be histamine, lipoids, fungi or proteins which are potential allergens. The problem is one of removing the harmful dust without contravening strictly defined conditions of temperature, humidity, freedom from strong draughts and adequate access to machines.

Mr. Hellyer reviewed modern apparatus for the collection of dust from industrial gaseous effluents and for the cleaning of atmospheric air during conditioning. He dealt most fully with the design, operation and characteristics of electrostatic precipitators. A recent type, the 'Precipitron', was designed for air-conditioning plant. Ionization takes place in this precipitator at a potential of 14 kV. and collection at 7 kV. Ionizing wires and charged plates are both positively charged, rendering ozone formation very small. A blackness test, using filter-paper disks, was described for measuring efficiencies. Numerous photomicrographs of industrial dusts were shown.

Points raised during the discussion on this session included the possibility of using oil treatment of the cotton during carding, recent experiments having shown very promising results. The high installation costs and the apparent drop in efficiency with time of electrostatic precipitators were mentioned by several speakers.

The three papers presented during the third session were "Practical Aspects of the Dust Problem, with Particular Reference to Flour Milling", by Leslie Smith; "The Dust Problem in the Photographic Industry", by R. G. R. Carnall; and "Surface Area in Dust Control", by P. J. Rigden.

Mr. Smith outlined present-day practice in dust control in flour-milling processes. High-speed exhaust systems with metal trunking and suction-type fabric filters are favoured. Current trends towards pneumatic conveyance of mill stock may necessitate installing complete air-conditioning plant.

Mr. Carnall presented the unique problem of preventing dust particles from reaching surfaces which could not be better designed to hold them. The solution lies in segregating dirty and clean work, providing special clothing for personnel and paying special attention to their health, forbidding the use of cosmetics and ointments, and using machinery as fully automatic and instrumented as possible. Bag filters, or the new 'Airmat' cellulose-wool filters, are used for air filtration because of their great reliability over long periods. Means of identifying dust particles embedded in photographic emulsions were described and illustrated by many photomicrographs.

Mr. Rigden described a method of measuring the surface area of dust samples, based on the well-known air-permeability method, but requiring samples of only 50 mgm. The pressure drop across beds of powder of sufficient length for accurate measurement is very high and necessitates special methods of measuring the flow of air. Direct weighing of air flowing through the bed into an evacuated bulb and the rise in pressure in such a bulb are the two methods used. Good reproducibility and agreement between the normal method using 10-gm. samples and the new method are attained.

Discussion during the third session showed particular interest in the methods used for dust suppression in the photographic industry. Many questions of detail were asked regarding the effect of sneezing and use of handkerchiefs and the precautions necessary during maintenance and overhauls.

The fourth session, which dealt with "Fire and Explosive Hazards", was held on the afternoon of September 29 under the chairmanship of Lieut.-Col. Sir Reginald Thomas. Six papers, which divided themselves naturally into three groups by their subject-matter, were presented, and discussion took place after each group.

The first two papers were "The Lower Inflammable Limit of Explosive Dusts and the Influence ofDiluents Thereon", by Dr. J. E. Garside; and "Gas Explosions and Dust Explosions, a Comparison", by Elwyn Jones and A. Grenville White.

Dr. Garside described a method of determining the lower limit of inflammability of dust–air mixtures. The dust is dispersed by violently displacing into the explosion vessel a felt pad supporting the dust from a lead tube down which a detonation wave is injected from an exploding air–gas mixture. The method is used to show how the lower limit varies from material to material, is dependent on the grain size of the dust, and can be raised to a safe value by mixing inert powders, such as limestone, with the dust.

Mr. Jones maintained that flame propagation in dust explosions as well as in gas explosions is a thermal process capable of interpretation in terms of calorific value of the mixture. Impossibility of obtaining a perfect mixture of solids and gases complicates combustion in dust explosions. It seems that, at lower limits, solid particulate fuels are capable of forming local centres of ignition and propagation. An important factor in this process may be the volatility of the fuel. An appendix described an apparatus for determining limits of inflammability, which largely removes the influence of settling-rate of the dust.

In the discussion doubts were expressed about the validity of the results obtained in a laboratory-scale experiment when applied to large-scale explosions, and on the possibility of obtaining an accurate figure for the concentration of dust at the time of explosion.

The second group of papers comprised "The Ignition of Dust Clouds by Electrostatic Discharges", by Prof. E. G. Cox and A. G. Peace; and "Coal Dust Explosions. Recent British Experiments", by Dr. F. V. Tideswell.

Prof. Cox, describing work done during the Second World War, showed that many dust clouds might be ignited by electrostatic discharge. The incendivity of a spark depends upon its characteristics, and such a spark has an optimum incendivity when in series with a resistance of value depending on the capacity being discharged. Thus a discharge from a movable bin or from operatives which are badly earthed or from a charged body to an imperfectly earthed conductor is very liable to cause dust explosions.

Dr. Tideswell stressed the real danger of explosions due to coal dust not only in mines but also in pulverized fuel plants. Some amelioration of the danger in mines is to be expected from the increase in wet-cutting and the spraying of coal in tubs and at loading points. Powdered hydrates such as gypsum are more effective in suppressing dust explosions than shale dusts, and their use would increase the margin of safety given by the statutory stone-dusting requirements. Work is proceeding on specially free-flowing stone dusts which will be easier to apply continuously.

The final two papers of this session were "Explosion Reliefs on Dust Plant", by Dr. D. Matheson; and "Precautions Against Fire and Explosion" by G. V. Thom and G. A. V. West.

Dr. Matheson said that in the present state of knowledge the safest thing to do is to build a dust plant strong enough to withstand full explosion pressure, or place it where it can blow up without causing other damage. Work now proceeding should enable explosion reliefs to be designed which will safeguard existing types of plant from bursting through internal dust explosions.

Mr. G. V. Thom presented a very full survey of the explosion and fire hazards met with in chemical industry. He stressed the importance of properly maintaining fire-fighting appliances and of instructing personnel in their use.

A report of the proceedings of Section V of this Conference has already appeared in *Nature* (January 15, p. 111).

CHEMICAL CONSTITUTION AND BIOLOGICAL ACTIVITY

PROGRESS in the interpretation of biological results in terms of chemical constitution is very slow. Except in chemotherapeutic investigations, attempts to correlate physical and chemical data with activity on animal tissues have proved disappointing, even allowing for the relatively low degree of accuracy in biological methods and the too frequent absence of specific knowledge of the mode of action.

At the present time some advances have been made by using drugs belonging to a homologous series, or containing different elements but possessing varying degrees of similar pharmacological activity. Furthermore, lines of research have been directed with drugs having similar structures but showing protagonist and antagonist action. When Dr. F. Bergel delivered his address on "Some Aspects of the Relationship between Chemical Constitution and Physiological Activity" to the Fine Chemicals Group of the Society of Chemical Industry on November 26, 1948, at the London School of Hygiene and Tropical Medicine, he mentioned that too much must not be expected from one or two series of data disclosing only a fraction of the overall constitution. Once a working hypothesis of mechanism of action is established, correlation should be attempted between physico-chemical measurements and biological activities.

During the course of his address, Dr. Bergel showed that, in the consideration of the validity of the expression connecting physiological action of a drug and its chemical constitution (Crum-Brown and Fraser, 1869), it is necessary to include those events which precede visible pharmacological effects. The picture is confusing; but two working hypotheses help to elucidate the mechanism of drug action. In the first or receptor theory, certain areas of the cell at the site of action combine with the drug, and these combinations are the cause of the biological action. Many drugs such as anæsthetics, analgesics, and autonomic derivatives, acting rapidly and in high dilutions, may find their receptors on the outside of the cell surface, while those influencing cell division or growth may react with constituents of the protoplasm. Methylene blue, with its atropine-like and anti-bacterial effects, provides a clear example of both external and internal reactions. In the second or enzyme receptor theory (supported experimentally by such work on B.A.L., inhibitors of cholinesterases, respiratory enzyme systems, and amino-oxidases), a number of these receptors are said to be identical with functional enzymes or proteins. Then, on the basis of competitive affinity and mass action, an explanation is possible for the selective potency of stereoisomers, the increase of activity in homologous series, and the antagonistic action of certain drugs similar to protagonist molecules. The fact that low concentrations of many substances may produce physiological stimulation or depression while higher concentrations cause the reverse effect is, however, not easy to explain.

Turning to the chemical side, Dr. Bergel stressed that, only with models based on correct inter-atomic distances, van der Waals radii and valency angles, apart from geometrical and optical isomerism, can the compactness and spatial distribution of the atomic aggregate be appreciated. In addition, the existence of electrovalent, covalent and co-ordinate bonds, lone electron pairs, bonds with dipole moments adding up to polar groups and to polarization of the molecule, oscillating dipoles, resonance and hydrogen bonding, must not be forgotten. It has already been shown in some series that a certain bond-distance appears to be optimal for maximal effects. But disappointing results have been obtained from other aspects, and pharmacological chemists have therefore had to rely on rather more empirical approaches. The aim has often been to find a pharmaco-dynamic group, that is, the structural minimum which still carries distinct activity, and this type of method is well illustrated by work on synthetic analgesics, such as morphine substitutes.

G. B. WEST

GERMAN SOCIETY FOR DOCUMENTATION

CONFERENCE AT COLOGNE

BEFORE the Second World War, the International Federation for Documentation, then the International Institute of Documentation, included a German section which, afterwards, was converted into a purely German affair under the Nazi regime. A conference of the Deutsche Gesellschaft für Dokumentation took place in Salzburg in 1942.

During December 9–10, 1948, at Cologne, another conference was held, the first since the War, with the aim of finding the way back to the broader outlook which might once again open up possibilities of international co-operation in the field of documentation. It was a re-organised Deutsche Gesellschaft für Dokumentation which sponsored this Conference, together with the Deutsche Normenausschuss, the Verband der Bibliotheken von Nordrhein-Westfalen, the Arbeitsgemeinschaft der Technisch-Wissenschaftlichen Bibliotheken and the Verein Deutscher Archivare. The Conference was attended by some 150–200 delegates from different parts of Germany, representing universities, libraries, learned societies, the legal profession, designers of apparatus, and industrial bodies, meeting on board a middle-size river boat equipped as hotel and restaurant.

The opening session was presided over by Prof. Schmölders, who welcomed the delegates on behalf of the rector of the University of Cologne, Prof. Kroll. The main speakers of this session were Dr. Vollmer, director of the Staatsarchiv at Düsseldorf, and Prof. Corsten, director of the Stadt- und Universitäts-bibliothek at Cologne. It was followed by a business meeting of the newly constituted society, election of officers, the formation of sub-committees and so on. Lectures, open to the public, were given at the University of Cologne by Dr. W. Schürmeyer, president of the Deutsche Gesellschaft, Mrs. L. Moholy, representing the Library Association and the Royal Photographic Society of Great Britain, and Dr. Pierre Bourgeois, director of the Bibliothèque Nationale Suisse.

The emphasis of the lectures, papers and subsequent discussions was on the various aspects of microphotography, its growth and development, its progress in different countries, its use in archives, libraries and bibliographical centres, its importance for scholars, scientific and research workers, the copyright position, and so on. Two copyright experts, Dr. O. Runge and Dr. Wildt, advocated the setting up of central agencies to simplify procedure (a suggestion also recommended in Great Britain), especially in cases where speed is essential. Prof. E. Reimer, another authority on the subject, was unable to attend.

To some extent the problems attached to the use of microfilms in Germany have been similar to those in Great Britain, though where the British often hesitate, the Germans have made quick decisions, and a variety of answers now strive for co-ordination. The requirements of *ad hoc* copying are distinct from those which govern organised reproduction; but any solution must keep within the provisions of a restricted economy. There seems to be scope for transparent as well as opaque material, flat shapes as well as long lengths, celluloid and 'Cellophane', high- and low-reduction ratio, microfilm with or without perforations, microcards, miniature prints, and so on, with the limitations mainly imposed by dearth of machinery.

To keep in check and, if possible, to standardize the existing variety of experimental methods, were among the aims the Conference set out to achieve. Apparatus, material and samples of work done were on view, to give practical backing to a number of technical points. It was, however, realized in the course of discussions that account must be taken of corresponding efforts carried on outside Germany, if international co-operation is to be restored, this being the other objective foremost in the minds of those who organised the Conference. The presence of foreign guests, including Mr. Donker Duyvis, general secretary of the International Federation for Documentation, to whom the Deutsche Gesellschaft für Dokumentation has now applied for re-affiliation, was welcomed as a hopeful sign in this direction.

L. Moholy

PHYSICS IN GERMANY

A DISCUSSION about the claims of technical physics to be regarded as a subject in its own right began at the International Congress for the Training of Engineers in Darmstadt in 1947, and has been carried on in *Physikalische Blaetter* (No. 8, 253; 1947. No. 1, 16; 1948. No. 3, 110; 1948), and is still going on.

Prof. C. Ramsauer, an eminent 'technical physicist' himself, founder and director of the A.E.G. Research Station, is emphatically opposed to the idea of technical physics as a special subject, although formerly there was a society devoted to it of which Prof. Ramsauer was president. Prof. Ramsauer states that during the First World War, both industrial and Government authorities were surprised at the superiority of 'pure physicists' over engineers in the solution of technical problems. Soon it was generally recognized that where new ground is to be tilled, it is not the routine of the engineer but the comprehensive grasp of fundamentals that assures success. The teaching of engineers, he believes, should be the same as that of all other physicists, supplemented in the advanced stages by technical courses not occupying more than one third of the total time, this total excluding mathematics and chemistry but including physical chemistry. The most grievous injury inflicted on German science by the Nazi regime was the substitution of the diploma examination for the doctor's dissertation; an examination deals with present knowledge whereas the thesis teaches the student to explore the unknown.

The opposite view has been advocated by Prof. Vieweg. He maintains that 'technical physics' must be a separate subject from the start. The technical physicist is a liaison officer between physics and engineering. Prof. Vieweg believes there should be mutual fertilization, and the term 'technical physics' expresses better than 'applied physics' this reciprocity. The task of technical physics is to loosen up and prepare the ground for technical development.

Prof. Ramsauer, after quoting replies to a questionnaire, most of which share his view, invites university authorities and industrial leaders to express their opinion about some concrete proposals which he sets forth. These include the demands that the term 'technical physics' should be completely dropped and that, as before, the doctor's degree should be the natural goal of every physicist's training. He calls this a matter of life and death for German science.

The Deutsche Physikalische Gesellschaft in der britischen Zone has declared at its board meeting of September 8, 1948, that it adopts the views of Prof. Ramsauer. It is of the opinion that there is no 'technical' physics, but only physics; technical physics is nothing but the application of pure physics to technical problems, and no special syllabus is required for such purposes. The Society considers that the introduction to technical mechanics and into electrotechnics should be taught at universities. Special technical problems ought to be dealt with in accordance with local conditions; however, they must not endanger the thoroughness of the general scientific education.

The obligatory doctor's dissertation is regarded as most important; its abolition during the Nazi regime was a great misfortune. The Society is most anxious that the 'diploma examination' should again be replaced by the 'doctorate examination'. In the meantime, it requests all authorities and firms to give preference to candidates who have obtained the doctor's degree. Gratification was expressed at the board meeting that its views are approved by the most important industrial firms.

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Saturday, February 19

Institute of Physics, Industrial Radiology Group (at 47 Belgrave Square, London, S.W.1), at 10 a.m.—Discussion on "Layout and Planning for Radiographic Inspection".

Monday, February 21

University of London (at King's College, Strand, London, W.C.2), at 5.30 p.m.—Dr. H. G. Thornton, F.R.S.: "The Ecology of Bacteria with Especial Reference to Soil".* (Further Lectures on February 28 and March 14.)

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 8 p.m.—Dr. W. H. J. Vernon: "The Corrosion of Metals". (Cantor Lectures.) (Further Lecture on February 28.)

Royal Geographical Society (joint meeting with the Royal Society, at Kensington Gore, London, S.W.7), at 8.15 p.m.—Prof. Hans Pettersson: "Exploring the Ocean Bed".

Tuesday, February 22

Royal Anthropological Institute (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Mr. W. G. Archer: "Primitive Indian Pottery".

Institute of Sociology (at the Royal Institute of British Architects, Portland Place, London, W.1), at 5.30 p.m.—Dr. G. Scott-Williamson: "The Family as a Basis of Society".

Institution of Electrical Engineers, Measurements Section (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Discussion on "Automatic Precision Instruments" (to be opened by Dr. A. T. Starr).

University of London (in the Department of Botany, King's College, Strand, London, W.C.2), at 5.30 p.m.—Prof. G. E. Blackman: "Modern Selective Weed Killers".*

Society of Public Analysts and other Analytical Chemists, Physical Methods Group (at the Institute of Physics, 47 Belgrave Square, London, S.W.1), at 6 p.m.—Papers on "The Spekker Photoelectric Absorptiometer and Fluorimeter".

Society of Chemical Industry, Fine Chemicals Group (in the large Anatomy Lecture Theatre, King's College, Strand, London, W.C.2), at 7 p.m.—Annual General Meeting; at 7.30 p.m.—Discussion on "Process Research in the Fine Chemical Industry" (to be opened by Dr. H. J. Barber, Dr. G. M. Dyson and Mr. F. J. Bolton).

Institution of the Rubber Industry, Scottish Section (at the Chamber of Commerce Rooms, Charlotte Square, Edinburgh), at 7.30 p.m.—Dr. W. McG. Morgan: "Accelerators for Stocks containing Reinforcing Furnace Blacks, Part 1, The Scorch Problem".

Wednesday, February 23

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Mr. Dunstan Skilbeck: "Training for Agriculture".

Geological Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Scientific Papers.

Linnean Society of London (in conjunction with the Systematics Association, at Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. H. K. Airy Shaw: "Post-Darwinian Development of Taxonomy (Botany)".

Manchester Literary and Philosophical Society, Chemical Section (at the Portico Library, Mosley Street, Manchester), at 5.30 p.m.—Dr. W. J. S. Naunton: "Rubber and Chemistry".

Society of Chemical Industry, Food Group (joint meeting with the Royal Entomological Society of London, at the Royal Sanitary Institute, 90 Buckingham Palace Road, London, S.W.1), at 6 p.m.—Dr. Colin G. Butler: "Some Observations on the Sense Physiology of the Honeybee"; Mr. J. Pryce Jones: "The Origin, Composition and Properties of Honey".

Thursday, February 24

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Harold Hartley, F.R.S.: The Berzelius Memorial Lecture.

Linnean Society of London (at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Discussion on "The Evolutionary Aspect of Colour Vision" (to be opened by Dr. P. J. Pumphrey).

University of London (in the Meyerstein Lecture Theatre, Westminster Medical School, Horseferry Road, London, S.W.1), at 5 p.m.—Prof. B. G. Maegraith: "Malaria as a World Problem".*

Institution of Chemical Engineers (joint meeting with the Low Temperature Group of the Physical Society, at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. E. W. Colbeck: "Materials of Construction for use at Low Temperatures".

Chemical Society, Hull Section (joint meeting with the Hull and District Section of the Royal Institute of Chemistry and the University College Scientific Society, in the Science Lecture Theatre, University College, Hull), at 6 p.m.—Prof. M. Polanyi, F.R.S.: "The Nature of Scientific Convictions".

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 6 p.m.—Prof. W. J. Duncan, F.R.S.: "Flutter and Stability".

Chemical Society, Nottingham Section (joint meeting with the University of Nottingham Chemical Society, in the Chemistry Department, the University, Nottingham), at 6.30 p.m.—Prof. C. A. Coulson: "The Shape of the Chemical Bond".

Chemical Society, Manchester Section (joint meeting with the Royal Institute of Chemistry and the Society of Chemical Industry, in the Engineers' Club, Albert Square, Manchester), at 6.45 p.m.—Dr. R. P. Linstead, F.R.S.: "Some Recent Developments in Organic Chromatography".

Chemical Society, Edinburgh Section (joint meeting with the Royal Institute of Chemistry and the Society of Chemical Industry, at the North British Station Hotel, Edinburgh), at 7.30 p.m.—Mr. R. C. Chirnside: "Analytical Chemistry, Chemical Analysis and the Analyst".

Friday, February 25

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Geophysical Discussion.

Chemical Society, St. Andrews and Dundee Section (joint meeting with the Royal Institute of Chemistry and the University Chemical Society, in the Chemistry Department, United College, St. Andrews), at 5.15 p.m.—Prof. C. E. H. Bawn: "Free Radicals and Hydrocarbon Chemistry".

Institution of Mechanical Engineers (at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Dr. P. Draminsky (Copenhagen): "Crankshaft Damping".

Chemical Society, Aberdeen Section (joint meeting with the Royal Institute of Chemistry and the Society of Chemical Industry, in the Chemistry Department, Marischal College, Aberdeen), at 7.30 p.m.—Prof. D. H. Everett: "Some Factors Influencing the Strength of Acids and Bases".

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. Hans Pettersson: "Through Three Oceans with the *Albatross*".

Saturday, February 26

Association of Scientific Workers, Agricultural Section (at the Society for Visiting Scientists, 5 Old Burlington Street, London, W.1), at 3 p.m.—Dr. Audrey Richards: "Problems of Colonial Development—an Anthropologist's Point of View".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Principal Scientific Officer in H.M. Nautical Almanac Office—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2404 (February 25).

Principal Scientific Officer in the Magnetic and Meteorological Department at the Royal Greenwich Observatory—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2402 (February 25).

Metallurgist (Ref. F/EV.36), an Analytical Chemist (Ref. F/EV.46), an Assistant Chemist (Ref. F/EV.47), and an Assistant (with good honours degree, or equivalent, with physics as the main subject) (Ref. F/EV.48), in the Central Laboratory at Chiswick—The Staff Officer, London Transport Executive, 55 Broadway, London, S.W.1, quoting appropriate Ref. No. (February 26).

Senior Lecturer in Chemistry at the Military College of Science, Shrivenham, near Swindon—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.38/49A (February 26).

Assistant Keepers (Class II) in the Departments of Chemistry, Optics, Astronomy and Mathematics—The Director and Secretary, Science Museum, South Kensington, London, S.W.7, endorsed 'Assistant Keeper' (February 28).

Bradford Dyers' Association Fellowship for research on fundamental problems in the industrial processing of textiles—The Registrar, College of Technology, Manchester 1 (February 28).

Head of the Electrical Engineering Department—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11 (February 28).

Senior Lecturer in Agriculture at Makerere College, Uganda—The Secretary, Inter-University Council for Higher Education in the Colonies, 8 Park Street, London, W.1 (February 28).

Principal Scientific Officers, Senior Scientific Officers, and Scientific Officers, at the Royal Aircraft Establishment, Farnborough, Hants, for work in connexion with the planning of future aircraft projects—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting A.451/48A (February 28).

Readership in Taxonomy in the Department of Zoology at University College—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 4).

Professor of Geology, and a Lecturer in Geology—The Registrar, University College of South Wales, Cathays Park, Cardiff (March 15).

Chair of Physiology at King's College, Newcastle-upon-Tyne—The Registrar, University Office, 46 North Bailey, Durham (March 31).

Lecturer in Acoustics, and an Assistant Lecturer, in the Department of Physics—The Registrar, The University, Liverpool (April 2).

Beit Fellowships for Scientific Research—The Registrar, Imperial College, South Kensington, London, S.W.7 (April 2).

Senior Lecturer in Pure Mathematics, and a Lecturer in Applied Mathematics, at the University of Natal, Pietermaritzburg; and a Senior Lecturer in Applied Mathematics, at the University of Natal, Durban—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.2 (April 11).

Chair of Geology at the University of Otago, Dunedin, New Zealand—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (April 16).

I.C.I. Research Fellowships for research in Physics, Chemistry, Biochemistry, Engineering, Metallurgy, Pharmacology, Chemotherapy, or related subjects—The Secretary, Board of Research Studies, The Old Schools, Cambridge (April 30).

Senior Chemist to the Rubber Research Scheme (Ceylon)—The Chairman, London Advisory Committee for Rubber Research (Ceylon and Malaya), Imperial Institute, South Kensington, London, S.W.7 (April 30).

Beit Memorial Fellowships for Medical Research—The Secretary, Beit Memorial Fellowships for Medical Research, Lister Institute, Chelsea Bridge Road, London, S.W.1 (May 14).

Head of the Mathematics and Physics Department, Rutherford College of Technology—The Director of Education, City Education Office, Northumberland Road, Newcastle-upon-Tyne 1.

Scientific Assistant for information service and abstract journal—The Director, Commonwealth Bureau of Animal Breeding and Genetics, King's Buildings, Edinburgh 9.

Senior Entomologist and Field Entomologists (3) in the East Africa Desert Locust Survey—The Under-Secretary of State, Colonial Office, Research Department, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Lecturer in the Department of Chemistry, Colour Chemistry and Dyeing—The Registrar, Technical College, Queen Street South, Huddersfield.

Senior Assistant in Physics in the Darlington Technical College—The Chief Education Officer, Education Offices, Northgate, Darlington.

Superintending Pharmaceutical Chemist by the Government of the Federation of Malaya for Medical Department—The Crown Agents for the Colonies, 4 Millbank, London, S.W.1, quoting M.N. 18288.3F.

Mineralogist Chemist in the Geological Division of the Lands and Mines Department of Tanganyika—The Director of Recruitment, Colonial Service, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Assistant Professor who is an honours graduate in Mechanical Engineering, and Lecturers (2) with honours degrees in Mathematics (one Lecturer with an honours degree in Electrical Engineering or an equivalent qualification, one Lecturer with an honours degree in Metallurgy or an equivalent qualification), at the Royal Naval College, Greenwich—The Secretary of the Admiralty (C.E. Branch 1), Admiralty, London, S.W.1.

ANGLO-AMERICAN CO-OPERATION IN COLONIAL DEVELOPMENT

THE developments in the campaign against the tsetse fly in Central Africa, and the recently published report of the Commission of Enquiry into the Swollen Shoot Disease of Cacao in the Gold Coast (see *Nature*, January 15 and 22, and February 19), have emphasized the importance of the contribution which science has to make to the health and development of the backward territories, and through them to human welfare generally. Furthermore, the very nature of the latter Commission, consisting as it did of scientific men selected from a list prepared by the United Nations Food and Agriculture Organisation, demonstrates the value of international co-operation in this field; and especially of regional developments, such as the conferences with the French, Belgian and Portuguese Governments, and the discussions with the French Government and other associated Governments on the possibility of co-operation in development schemes to which the Colonial Secretary, Mr. Creech Jones, referred in a House of Commons debate on Colonial affairs last July. Mr. Creech Jones clearly recognized that in such areas as West and Central Africa, co-operation between these Powers in tackling the fundamental problems of Colonial development is all-important.

The fourth proposal made by President Truman in his inaugural speech on January 20, namely, that the United States should embark on a bold new programme for making the benefits of her scientific advances and industrial progress available for the improvement and growth of under-developed areas, will therefore be widely welcomed. Mr. Truman said :

> "More than half the peoples of the world are living in conditions approaching misery. Their food is inadequate. They are victims of disease. Their economic life is primitive and stagnant. Their poverty is a handicap and a threat both to them and to more prosperous areas. For the first time in history humanity possesses the knowledge and skill to relieve the suffering of these peoples.
>
> "The United States is pre-eminent among nations in the development of industrial and scientific techniques. The material resources which we can afford to use for the assistance of other peoples are limited. But our imponderable resources in technical knowledge are constantly growing and are inexhaustible. I believe that we should make available to peace-loving peoples the benefits of our store of technical knowledge . . . and in co-operation with other nations, we should foster capital investment in areas needing development. Our aim should be to help the free peoples of the world, through their own efforts, to produce more food, more clothing, more materials for housing and more mechanical power to lighten their burdens. We invite other countries to pool their technological resources in this undertaking. Greater production is the key to prosperity and peace. And the key to greater production is a wider, more vigorous application of modern scientific and technical knowledge."

This invitation to a co-operative enterprise in which all nations work together through the United Nations and its specialized agencies, wherever practicable, could scarcely have been issued unless there lay behind it the draft of a project in which ways and means are dealt with in considerable detail. It is true that President Truman linked this proposal with the continuance of support of the United Nations and of the European Recovery Programme as well as with the support of freedom-loving nations against aggression by regional pacts, such as those embodied in the treaty of Rio de Janeiro or at present being worked out for the North Atlantic Area. Nevertheless, it is not easy, even with the precedent of the Colonial Development Corporation before us, to visualize the exact means by which this idea of co-operative capital development can be made to work.

Capital investment is admittedly one of the fundamental needs of the backward areas ; but even if the proposal means that the United States are prepared to take over the role of leadership in this century which Britain filled in the last, the task is immensely more complicated. Against the greater advantages and resources for human welfare which science and technology have given us to command, there have to be set the growth of nationalism and the extent to which the expectations of the under-privileged everywhere have been magnifying the standards achieved in more prosperous countries. Even without the existence in Communism of a political force which not only makes these aspirations articulate but also may confuse the issues to support a rival bid for world leadership, the task of reconciling opposing, or apparently opposed, interests will be far from easy. The report of the Commission of Enquiry into the Swollen Shoot Disease of Cacao in the Gold Coast provides sufficient illustration of the way such considerations may intrude on a purely scientific or technical problem.

Mr. Truman's statement was warmly welcomed by the Foreign Secretary, Mr. Bevin, in his speech to the Foreign Press Association on January 25. Mr. Bevin thought that all the Powers responsible for overseas territories would throw into the pool all the knowledge, ability and resources they had at their command. Successive Colonial Secretaries have already made plain the readiness of Britain to associate herself with schemes of regional development in the Caribbean, Africa and elsewhere, while at the same time dissociating themselves from any idea of international government. Discussions, in fact, have already taken place in Paris on the possibility of closer economic co-operation between France and Great Britain in their Colonial territories.

Unfortunately, the Trusteeship Council of the United Nations has so far conspicuously failed to win the respect accorded by the Colonial as well as the Mandatory Powers to the Permanent Mandates Commission of the League of Nations. Time will be required to dispel the suspicion that the new Council is being used mainly as a sounding board for irresponsible and destructive criticism and not as an organ of co-operation. Meanwhile, quite apart from the fact that the whole trend of President Truman's statement indicates that he is prepared to use other agencies where the specialized agencies of the United Nations are ineffective, there has already been demonstrated a growing measure of international co-operation in the scientific and technical field, and it is on this field that President Truman laid particular stress. No such obstacles as may beset the proposition for co-operative capital development, with the necessity for dovetailing such projects very carefully with the demands made under the Marshall Plan, need hinder the spread of technical knowledge in these undeveloped areas.

That in itself is a long-term project which will require time for fruition. There are, however, various ways in which the United States could probably render immediate and direct assistance. Thus it could share its own pre-eminent development of industrial and scientific techniques at no great cost by broadening the facilities offered to students of all nations to study in the universities and technical institutes of the United States. This would do much more than simply ease the great strain placed on the over-crowded universities of Great Britain through the admission of increased numbers of overseas students and co-operation in the development of the new universities throughout the Colonial Empire. The students may be expected to carry back to their own lands both knowledge and also an enduring appreciation of the American way of life.

Whether such help is given in the form of men and women, or of space in educational institutions, or of finance—and in few fields could a relatively small financial outlay bring such a large return—it can only be welcomed by Britain and other Colonial Powers. At first, indeed, it can only be on a small scale, for students well equipped to profit by the opportunity will not easily be found until education has further advanced in the African and other backward territories concerned. Some part of the American effort might accordingly take the alternative form of assisting educational enterprises in lands that have not the resources to break the fetters of illiteracy for themselves.

Significantly enough in this connexion, it may be recalled that the Colonial Office has already asked the United States Economic Co-operation Administration whether American men of science and technicians could fill posts in the Colonial Geological Survey and the Colonial Geodetic and Topographical Survey until the recruiting position caused by the gap in training during the war years improves. The vacancies are for reconnaissance work required before new areas can be opened up for mineral and other development, and the recruitment of some fifty Americans in this way would be a notable step in the pooling of experience. It would be a manifestation of Anglo-American partnership in service which might well contribute to the spread of Anglo-American ideas and principles in a way comparable to the permeation of Indian thought in the last century by the ideas of British educationists.

President Truman's proposal should give a further stimulus to the zeal and enthusiasm lying behind some of the striking achievements of science and technology, which are opening up new opportunities for human welfare and economic development in Africa, and to the international and regional co-operation required to realize those possibilities. It should be remembered that, more than a year ago, in a speech in the House of Commons on January 22, 1948, the Foreign Secretary linked the development of the backward areas with the economic recovery of Western Europe. The imaginative passage in which Mr. Bevin urged the closest possible collaboration between the British Commonwealth and French, Dutch, Belgian and Portuguese as well as British overseas territories, should be set beside Mr. Truman's recent proposal.

Neither Mr. Truman nor Mr. Bevin pursued the idea into any detail. Mr. Bevin was content to emphasize that there is no inherent conflict between the social and economic development of these overseas territories to the advantage of their peoples and their development as a source of supplies for Western Europe and a contributor to the balance of payments. President Truman has clearly responded to this vision of the tremendous resources of the Middle East, Africa and the Far East being brought together, with European and American resources, for the purpose of making the whole world richer and safer. The significance of his proposal lies less in its novelty than in the evidence of American response to a challenge for economic and social planning on a bolder and more imaginative scale than the world has yet seen.

ISOTOPES IN BIOLOGY AND MEDICINE

A Symposium on the Use of Isotopes in Biology and Medicine

Contributors: Hans T. Clarke, Harold C. Urey, Glenn T. Seaborg, Paul C. Aebersold, Alfred O. Nier, Charles D. Coryell, Martin D. Kamen, Donald B. Melville, David B. Sprinson, Harland G. Wood, Konrad Bloch, David M. Greenberg, I. L. Chaikoff, Joseph G. Hamilton, Byron E. Hall, Saul Hertz, William F. Bale, James J. Nickson, Farrington Daniels. Pp. xiv+445. (Madison, Wis.: University of Wisconsin Press, 1948.) 5 dollars.

Advances in Biological and Medical Physics

Edited by John H. Lawrence and Joseph G. Hamilton. Vol. 1. Pp. xi+484. (New York: Academic Press, Inc.; London: H. K. Lewis and Co., Ltd., 1948.) 8.60 dollars.

Radioactive Indicators

Their Application in Biochemistry, Animal Physiology, and Pathology. By George Hevesy. Pp. xvi+556. (New York and London: Interscience Publishers, Inc., 1948.) 60*s*.

THESE three comprehensive volumes dealing with biological and medical applications of isotopes appear within a few months of each other, and mark a milestone in the subject. The rate of development in this field has been so rapid that the opportunity has scarcely arisen to take stock of progress. With their appearance a panoramic view of the literature is provided, with the help of which it becomes possible to assess what has been achieved and to speculate on future developments.

In the first place one is struck by some unusual, if not unique, facts about this new subject. There is, for example, the remarkable feature that it owes its development almost entirely to one man in Europe and to a large number of able investigators in America. This is reflected in the authorship of these books, which comprises G. Hevesy and thirty-one North American contributors. In the case of the radioactive isotopes, this feature may also be looked upon as a reflexion of the distribution of usable cyclotrons during the war years. Whatever truth there may be in this, it must be a cause of general satisfaction that the initial period of unequal opportunity is practically at an end and that isotopes are now within the reach of almost everyone.

It is also doubtful whether any other subject of present or past popularity can lay claim to such a wide audience. Listed among the contributors to these volumes are physicists, chemists, biochemists, physiologists, physicians and radiotherapists, each of considerable eminence in his own subject. In the case of the symposium held at Wisconsin, many of these were brought together in harmony around the same conference table, which is no ordinary occurrence in this specialized age.

Surveying some of the achievements, there is in the medical field the rapid estimation of thyroid efficiency, the location of extra-glandular thyroid tissue and the therapeutic destruction of malignant tissue whether in the gland or in functional secondaries, all by the use of radioactive iodine. This field is conservatively reviewed by I. L. Chaikoff, A. Taurog, S. Hertz and C. P. Leblond. Hevesy and P. F. Hahn set out the satisfying story of the conservation of iron in the body, particularly in relation to the life-span of the erythrocyte. The metabolism of compounds of nitrogen and carbon is reviewed by B. Vennesland and of proteins by D. B. Sprinson. Without detracting from the outstanding merit of their articles, the omission of D. Rittenberg's name from the list of contributors will not pass unnoticed. Much of his earlier work in association with R. Schoenheimer is dealt with in an article of excellent historical perspective by Hans Clarke. H. G. Wood writes on carbohydrate metabolism, whether studied indirectly with radiophosphorus or directly with carbon and deuterium. He makes no claim to completeness, and in this he has clearly been wise, since the prevailing enthusiasm for this field of work is such that in the interval since the article was written there has appeared little short of an avalanche of papers.

We owe to Hevesy more than to anyone the important conception of turnover-time, which shows signs of furnishing the basis for an entirely new point of view in biochemistry. His method of determining it, to take the case of phosphorus compounds as an illustration, is to maintain constant the specific isotopic activity of plasma phosphate and to compare it with the specific activity of the tissue compound at the end of an interval which is short in relation to the time required for complete renewal. This is the experimental basis of his statement (p. 279) that 20 per cent of the lecithin in rat liver is renewed every four hours. He fully recognizes that the value will be affected if the specific activity of intracellular inorganic phosphorus is not the same as that of plasma inorganic phosphate; in other words, the permeability of the cell membrane affects turnover time as determined by his method. However, it was

D. B. Zilversmit *et al.*[1] who first stated clearly in 1943 that the method could be seriously at fault if certain circumstances prevailed. For example, this will be the case if lecithin phosphorus happens to be derived by a rapid exchange from liver glycerophosphoric acid, which in turn happens to be synthesized only slowly from plasma phosphate. In such a case, over a short period of observation the isotope may scarcely reach the lecithin, whereas a considerable exchange of phosphate between lecithin and glycerophosphoric acid will have taken place. As Chaikoff and Zilversmit emphasize in their salutary article, it is essential to identify the immediate precursor, and Hevesy (p. 250) unequivocally supports their contention.

It will be helpful to many to find that this measure of agreement now exists between the experts. On the other hand, it was fortunate for the development of the subject that Hevesy should have adopted the less stringent conception of turnover time in his early work, since it is clearly better to have approximate figures to correct than none at all. This is certainly the choice, since the data required in order to apply the more precise method of the American workers are unobtainable for most intracellular substances or radicals. Fortunately this is not so in the case of plasma compounds, since the method of choice here, namely, to inject the labelled substance and observe its rate of disappearance from the plasma, makes no assumptions about the nature of the immediate precursor.

D. M. Greenberg writes on mineral elements, especially those of the skeleton and those possessing catalytic function, for example, iron, cobalt, manganese and zinc. Medical and therapeutic applications are left to E. C. Dougherty, J. H. Lawrence, J. G. Hamilton and B. E. Hall. There is a useful article by D. B. Melville on the preparation of compounds labelled with deuterium, carbon, nitrogen and sulphur.

A significant sign of the times is the inclusion of articles on health protection by H. M. Parker, W. F. Bale and J. J. Nickson. These are particularly timely in view of the increasing popularity of long-lived isotopes, particularly carbon-14 and iron-55, and of penetrating gamma-emitters, such as cobalt and zinc. Considerable space is devoted to the preparation and assay of isotopes, and the remaining names on the title-pages are mainly of contributors to these aspects. Much of the subject-matter here has appeared in review articles in physical and chemical journals, but its inclusion in volumes intended for the biologist is none the less welcome.

The popularity which isotopes have achieved in little more than a decade has been remarkable. It is safe to say that the next decade will see fresh discoveries in the field, but also, one hopes, the appearance of a more critical attitude to claims already made and recorded in these volumes. Following the spectacular demonstration of iodine uptake by the thyroid gland, the belief has grown that, provided an isotope emits gamma-radiation which is penetrating enough, it is only necessary to place a Geiger counter over the appropriate region of the body to derive the whole story of the isotopic uptake and excretion of a particular organ. The fallacy here is not based solely on the poor directional qualities of gamma-radiation but also on the fact that there are few sites in the body which compare with the thyroid in ability to concentrate elements selectively. Almost everywhere else, and with almost all other isotopes, there exists alike in the organ and in the surrounding tissues such a conglomeration of isotopic compounds, with vastly different exchange-rates, that the uptake and excretion by a region or organ as a whole have no useful significance.

Even where this is fully appreciated and the investigation is limited to an isolated compound, the biochemical difficulties of the isolation are, in many cases, only beginning to be appreciated. Tissue cells abound in macromolecules of high adsorptive capacity, with which are associated smaller diffusible molecules, frequently of high isotopic content. A few specialists in the field of surface chemistry have fully appreciated the tenacity of this adsorption, but many working with isotopes are apparently only now discovering it. In a recent investigation of the yeast cell[2] nearly all the phosphorus compounds isolated were found to be contaminated to some extent with other phosphorus compounds, especially metaphosphate, leading the authors to the conclusion that the results obtained from tracer experiments in general should be treated with great reserve until the fractions obtained have been reproduced by alternative methods of fractionation. Many, including the writer, will agree with this.

It is a pleasure to recommend all three volumes to serious workers in this field. For others, where a choice must be made, it is not possible to be categorical. Hevesy, in his monumental volume, has all the advantages of unity of authorship and maturity of outlook, but unavoidably he is not so reliable in some fields as the specialist contributor to the other volumes. Stable isotopes are excluded from his book, and some aspects of radioactive ones are not covered at all. Lawrence and Hamilton, on the other hand, have obtained the collaboration of specialists, including Hevesy, who are representative of the isotope field as a whole. Their articles dovetail much better than those in the symposium volume, which also shows some signs of hasty preparation.

A. S. McFarlane

HIGH-POLYMER PHYSICS

Mechanical Behavior of High Polymers

By Assist. Prof. Turner Alfrey, Jr. (High Polymers, Vol. 6.) Pp. xiv+581. (New York and London: Interscience Publishers, Inc., 1948.) 9.50 dollars.

THE unusually wide range of subjects covered by this work, the sixth volume in this series of monographs on high polymers, makes it difficult to give an adequate idea of its contents and method of approach in a short review. The book begins with what might be called an introduction to rheology—a concise treatment of the classical theory of elasticity, flow in Newtonian and non-Newtonian liquids, plasticity and thixotropy, and the simpler types of visco-elastic behaviour. This is followed by a discussion of the molecular mechanism of flow in amorphous linear polymers, and its formal analysis in terms of model systems, leading up to the development of the concept of a distribution of 'retardation times' or 'visco-elastic spectrum', from which the behaviour of a body under any type of stress variation may be derived. The third chapter deals with the statistical theory of the elasticity of cross-linked polymers (rubbers), and the statistical approach to the study of cross-linking and copolymerization—a fascinating field in which the correspondence between theory and experiment is refreshingly close—and associated problems.

In the remaining chapters the emphasis is on the observed properties of materials. Subjects dealt with are crystallization and its effect on mechanical properties of rubbers and fibres, the mechanical behaviour of wool and rayon, solution properties and plasticization of polymers. The final chapter deals with the question of tensile strength, both from the theoretical and experimental points of view.

Regarding the book as a whole, the treatment generally is sufficiently detailed and extensive for the reader to obtain a very fair grasp of the more important contributions to the subject, even without consulting the original literature. In many places sections of the original papers are quoted *in extenso*, which is extremely helpful for the reader who is actively engaged on research in a particular subject. On the other hand, this method has the drawback of breaking up the smooth development of the subject, making the presentation appear somewhat disjointed, with different parts of the same subject cropping up in various places. It is unfortunate that the section on optical properties could not have included a reference to the work of Kuhn and Grün (1942) on the statistical theory of the photo-elasticity of strained rubber.

The author is at his best in dealing with the general mathematical theory of visco-elastic phenomena, a subject to which he has made important contributions, some of which are set out in mathematical appendixes. The reviewer knows of no other book in which this subject is discussed in anything like the same detail, nor in such a masterly and lucid manner. Mathematics, however, is not physics, and the number of examples in which this kind of formal analysis has been successfully applied to real materials is still quite small. Moreover, there is the very serious difficulty (explicitly stated on p. 218) that the theory discussed is not applicable when the deformations encountered are large. Just as, in rubber elasticity, it has been found necessary to get right away from the classical (small-strain) theory and develop a theory in which large strains are included right at the start, so it may be necessary ultimately to develop a genuinely large-strain visco-elastic theory for the analysis of the non-equilibrium phenomena encountered in rubbers and plastics.

This is not a book for beginners; but for those who already have some knowledge and experience in high-polymer physics, it will be highly valued not only as an everyday guide but also, and perhaps primarily, as a source of inspiration for further research. L. R. G. TRELOAR

MECHANISM OF MAGNETIZATION

Paramagnetic Relaxation

By Prof. C. J. Gorter. Pp. vii+127. (New York and Amsterdam: Elsevier Publishing Co.; London: Cleaver-Hume Press, Ltd., 1947.) 12*s*. net.

ALTHOUGH Langevin's theory of paramagnetism is known to every physics student, the study of the mechanism of the magnetization process is comparatively new; Waller's first calculations were published in 1932, and experimental investigations may be said to begin with Prof. C. J. Gorter's first paper in 1936. Since then it has been intensively studied under his leadership in several of the Dutch universities: but, up to the present, many of the results have been published only in the form of theses. This monograph, written in Holland during the 'starvation winter' of 1944–45, is the first book to be devoted to the subject.

The magnetization of a paramagnetic salt is an equilibrium between the forces exerted on the magnetic ions by the magnetic field, the random forces of thermal agitation, and the constraints due to interactions either among the magnetic ions themselves or between the ions and the surrounding crystal lattice. When this equilibrium is disturbed by a change of magnetic field, it can be re-established only by a flow of heat, which proceeds at a rate which can be described in terms of two characteristic relaxation-times. As the time for the establishment of thermal equilibrium among the magnetic ions, or spin relaxation-time, is generally appreciably shorter than that for equilibrium between the ions and the crystal lattice, and also has a different dependence on magnetic field, it is possible to separate the two effects experimentally.

After a brief review of the theory of paramagnetism, Prof. Gorter surveys the experimental methods used in relaxation work. Essentially, these are measurements of magnetic dispersion or absorption at different frequencies; but, as the relaxation times range from spin relaxation-times of 10^{-10} sec. to lattice relaxation-times which at low temperatures may exceed 0·1 sec., a great variety of techniques has been employed. The high-frequency circuit work is nowhere very elaborate—it must be remembered that the whole of the work described is based on 'pre-radar' radio technique—but some of the methods used are beautifully simple, notably the work of H. Volger. There follows a summary of the experimental results, and a discussion of their significance in the light of the theory of lattice and spin relaxation.

For many readers the greatest interest will lie in the values which emerge for the magnetic specific heats. When the spin relaxation-time is sufficiently short compared with the lattice relaxation-time, measurements at a suitable frequency give the magnetic susceptibility under adiabatic conditions, in which the magnetic dipoles, although in thermal equilibrium among themselves, are effectively isolated from the surrounding crystal lattice. From this measurement, combined with that of the ordinary isothermal susceptibility, the specific heat of the dipole system can be obtained by a simple thermodynamic transformation. In the few cases in which the comparison is possible, this elegant method gives specific heats which yield values for the magnetic energy-levels in good agreement with those obtained by other methods. The experimental results on relaxation-times, on the other hand, have not yet been fitted into a satisfactory theoretical framework. The dependence of the lattice relaxation-times on magnetic field is not consistent from one substance to another, while the experimental data do not yet suffice for a full analysis of its temperature dependence.

While its appeal is necessarily specialized, Prof. Gorter's book is an important contribution to the study of paramagnetism. It is beautifully produced and printed—an important point in a monograph containing so many numerical data. It has no index.

A. H. COOKE

Practical Five-Figure Mathematical Tables

By C. Attwood. Pp. v+74. (London: Macmillan and Co., Ltd., 1948.) 3*s*.

ALTHOUGH the contents of this volume do not differ essentially from those normally to be found in books of this kind, many innovations have been introduced in the arrangement and presentation, and the author has spared no pains to ensure that the comparatively limited space available is utilized to maximum advantage and efficiency. In addition to the ordinary tables of common logarithms, there is a supplementary table covering the range 1·000–2·099 at intervals of 0·01, and a similar feature appears in the trigonometrical sections, where entries are provided at 1′-intervals for cotangents and cosecants up to 18° and for secants and tangents in the range 72–90°.

Great emphasis has been laid, both in the preface and in a final explanatory section, on the use of proportional parts. The author explains, by means of well-chosen examples, the various methods that are available for avoiding or reducing the inaccuracies produced by mean proportional parts. The use of smaller ranges, where necessary, has already been mentioned and occurs constantly throughout the book. Other methods include backward interpolation, the use of inverse tables, and Bessel interpolation with second-order differences. Several illustrations compare and contrast the results of their application.

Other tables supplied include squares, cubes, square and cube roots, reciprocals, exponentials and hyperbolic logarithms; and the author has been wise enough to ensure that all differences to be subtracted are printed in red. He claims that more than 95 per cent of the 160,533 possible combinations of mean proportional parts produce no error or an error of one unit in the last figure, while less than 0·6 per cent produce an error in excess of three units. In a few cases, where the error is liable to exceed five units, italic type has been employed as a warning.

The book is beautifully printed and should prove a valuable asset in all elementary numerical work.

J. H. PEARCE

Technical Literature

Its Preparation and Presentation. By G. E. Williams. Pp. 117. (London: George Allen and Unwin, Ltd., 1948.) 7*s*. 6*d*. net.

MR. G. E. WILLIAMS' book is an expansion of his paper "The Presentation of Technical Literature", published in the *Journal of the Institution of Electrical Engineers* in 1944. To the extended sections of that paper Mr. Williams has now added chapters on the preparation of manuscripts, the art of sub-editing and on illustrations, and he also appends some notes on editing standards. In these respects his book differs from that of Prof. Kapp on "The Presentation of Technical Information", and although similar in scale and alike in their emphasis on the technical ideal that the treatment of a theme and the choice of words should be determined by their fitness for the purpose to be served, there are marked differences between these two books. Mr. Williams is concerned only with the writer, whereas Prof. Kapp deals with the lecturer also.

While the psychological approach is not overlooked, Mr. Williams emphasizes the factor of interest in his introduction—psychological principles bearing on the communication of knowledge are discussed separately in an appendix. Here Mr. Williams seems to be less successful than Prof. Kapp, though it is only fair to point out that these few pages are intended to serve no more than as an introduction to the subject, and that, unlike Prof. Kapp, Mr. Williams gives his readers clear guidance as to where further help may be sought. He includes a bibliography which, if not extensive, is adequate and discerning. The book is severely practical. It is lucid, well written and much to the point. For all the merits of Prof. Kapp's book, that of Mr. Williams will be preferred by many—and those not only the engineers and physicists primarily addressed—because, although slightly shorter, it is comprehensive and guides the student to the further sources where he may study, in greater detail, particular questions that arise in writing technical literature.

R. BRIGHTMAN

Notions fondamentales sur les vernis et peintures

Par Louis Kientz. Pp. xxi+234. (Paris: Gauthier-Villars, 1947.) 475 francs.

THE purpose of this book is "to inform the technician on the nature and properties of paints and varnishes". Such a limited aim the work fairly well achieves. Thus, there are chapters on resins, oils, pigments, paint testing and the like, where the information, if not novel in tenor or presentation, is of the kind likely to be useful to the paint technologist. However, some unfortunate statements have found their way into the text. Thus, to condemn fillers as solely useful for cheapening a paint, and as finding no place in a first-quality product (p. 70), is unnecessarily exclusive. It is a great pity that nothing better to illustrate the text could be found, assuming that illustrations are necessary, than a handful of ill-executed and uninformative line-drawings. The title is most misleading. It is true that a section will be found devoted to the theoretical concepts of physical chemistry, and throughout the text are scattered discussions on such matters as the mechanism of oil oxidation, structural formulæ of complex molecules, etc.; but these disquisitions are marred by a diffuseness and a lack of precision that render them more confusing than enlightening. Reference may be made, in illustration, to the inadequate treatment of viscosity and "rigidity" [*sic*] (p. 16), by which is meant anomalous viscosity, and of the classification of drying, semi- and non-drying oils (p. 45). Such imprecision, it must be admitted, is inescapable in a work almost purely descriptive; even the section on paint-testing is almost wholly uncritical. The absence of an index must seriously limit the value of this book as a work of reference.

Brachiopoda and Mollusca from the Productus Limestone of the Salt Range

By Dr. F. R. Cowper Reed. (Memoirs of the Geological Survey of India. Palæontologia Indica, New Series, Vol. 23, Memoir No. 2.) Pp. xii+596+65 plates. (Calcutta: Geological Survey of India, 1944, distributed 1948.) Rs. 63.2 or 96*s*.

ONLY a palæontologist who has lived through much of the development of his science could produce a volume such as this. The brachiopod and molluscan fauna of the Productus Limestone is described in detail with a wealth of references. Though only two new genera, *Blandfordina* (Limidæ) and *Palæolecanites* (Lecanitidæ), and one new sub-genus, *Haydenella* (*Productus*), are found necessary, there are no fewer than 177 new species and 114 new varieties. In this revision of the fauna certain of the conclusions reached by Waagen in an earlier monograph are rejected. In particular, the supposed

Visean affinities of a number of species from the Lower Productus Limestone, and the proposed palæontological zoning of the Middle and Upper Productus Limestone, are shown to be unsupported by evidence. The present author considers the Productus Limestone to be wholly Permian in age.

This work enables closer correlation to be made with Permian beds in other regions, and extremely close relations are apparent with faunas from West Australia, China and Tunisia. There are many anomalies, however. The rich faunas from Indo-China and Timor, for example, contain few identical species, and many of the gastropods are "extraordinarily like" those of the Pennsylvanian of America. Arctic species occur in all three divisions of the Productus Limestone. The author would prefer to regard many of the differences of fauna between Asiatic regions as indicating ecological (facies) variation rather than actual difference in age.

ALAN WOOD

Fishes and Shells of the Pacific World

By John T. Nichols and Paul Bartsch. (Pacific World Series.) Pp. v+201+16 plates. (New York: The Macmillan Company; London: Macmillan and Co., Ltd., 1946.) 12*s*. 6*d*. net.

THIS book provides an authoritative introduction to Pacific fishes and molluscs, and was written primarily to assist the thousands of service men spread over the Pacific Ocean during the latter half of the recent War. The descriptive section on the fishes is illustrated by a number of clear line drawings which are probably of even greater practical value than the photographs which illustrate the section on molluscs. The authors make no attempt to give a complete survey of these groups, but enough detail is provided for anyone to allocate a fish or mollusc to its family or genus. The book is, however, by no means confined to systematics; there are chapters on the origin and distribution of the fishes, on game fishes, and on the collection and preservation of fishes and molluscs.

In the section on molluscs there is a concise account of the chemical and physical factors in the sea, with a discussion of the part played by molluscs in the economy of the sea. There is a good short bibliography appended to the mollusc section of the book, but unfortunately there are no further references on the fishes.

Further popular books of this standard, covering other areas of the world, would be of great value, perhaps even in Great Britain, where many animal groups are still served by handbooks rapidly approaching their centenary.

Nuts

Their Production and Everyday Uses. By Dr. F. N. Howes. Pp. 264+16 plates. (London: Faber and Faber, Ltd., 1948.) 18*s*. net.

THIS is one of those useful books which present simply and shortly all but the more specialized aspects of one particular and comparatively limited subject—in this case the seeds and fruits that are popularly called 'nuts'. Apart from short introductory sections about the uses of nuts for food and their processing and storage, and an end section of cooking recipes, the book is in four parts, dealing respectively with tropical nuts, temperate nuts, nuts in Great Britain, and less familiar sorts. It is well produced and printed, and the illustrations as good as can be expected with such a subject.

As the author says, "most people relish nuts", especially children, and it is interesting to speculate how far this may come from the earliest days of human history when, it seems likely, nuts were one of the chief sources of food, especially in the warmer forest areas, where, indeed, they are still of much greater importance than elsewhere. Another interesting point is the way in which the book illustrates how various are the circumstances which may make or mar a vegetable commodity for purposes of modern commerce, a fact that may, in part, explain why the commercial plant-products of really first-rate importance are so few. Keeping qualities, the presence of unpalatable substances, the thickness of shells, the clinging of skins, the growth-form of the plant, the length of generation, and difficulties of harvesting or processing are but a few of the reasons why, among nuts at any rate, it seems that "the best is still to come".

Dr. Howes no doubt found it difficult to weigh fairly the claims to space of his different subjects, and on the whole he has kept a reasonable balance; but some disturbance of it might have been justified to allow consideration of so topical a matter as the African groundnut scheme. The statement, too, that this plant, which is assumed to be a native of America, has been cultivated in the Old World for "many centuries" is likely to raise some unnecessary hares. There might also be a more consistent insertion of the names of the families to which the various nuts mentioned belong. A detail of the book which is likely to appeal particularly to readers in Great Britain is the interesting account given of garden almond-trees. These often fruit surprisingly well, even on the rigorous north-east coast, where last year, for example, individual trees bore as much as thirty pounds of good fruit; Dr. Howes' reminder that the nuts from these fruits are usually perfectly palatable and wholesome is timely.

RONALD GOOD

Physics and the Surgeon

By H. S. Souttar. Pp. vii+60. (Oxford: Blackwell Scientific Publications, Ltd., 1948.) 7*s*. 6*d*.

THE mention of physics in any assembly of surgeons or physicians can be relied upon to arouse an immediate feeling of apprehension. An outstanding exception to this attitude is Mr. Souttar, who, besides being a surgeon of international standing, has acquired considerable repute as a physicist and mathematician. Unfortunately, the hopes raised by this combination of title and author are doomed to disappointment. The first half of the present book deals mainly with the mechanics and hydrostatics of human anatomy. There are fascinating accounts of the forces involved in muscle action, though the author is often so carried away in descriptive anatomy that the physics is left far behind.

The remainder of the book is devoted to atomic physics. In about thirty pages the reader is carried from the Rutherford atom, through the quantum theory, spectra, X-rays and radioactivity, taking in the cyclotron and isotopes in his stride. One is rather surprised to find that in a book dated 1948 the word 'neutron' appears only once, and the only instrument for detecting atomic particles mentioned is the spinthariscope. The many applications of atomic physics to surgery and medicine are not mentioned.

This book would need considerable expansion and revision in order to fulfil the promise of its title.

J. E. R.

THE UNIVERSITY COLLEGE OF THE WEST INDIES

MR. CREECH JONES, the Secretary of State for the Colonies, announced in January that a Royal Charter had been granted incorporating the University College of the West Indies, that the King had consented to accept the office of 'visitor', and that Princess Alice, Countess of Athlone, had been appointed the first Chancellor. The College does not possess power to grant degrees; its students will sit for the degree examinations of the University of London, until it has fully established its academic reputation and standards. The constitution has been so drafted that only minor changes will be needed when the College reaches the stage at which it feels justified in seeking university status.

The University College now enjoys full constitutional autonomy. The academic staff is strongly represented on the governing Council, and the Senate's control of academic policy is protected by the provisions of the Charter. The College has been admitted to the privilege of the "special relationship" with the University of London, which permits the teaching staff to propose changes adapting the curriculum to local opportunities and needs and to participate in the examining. This relationship guarantees the standard of the degrees, and at the same time gives the College a wide measure of freedom in linking teaching and examining to the research interests of the staff and to the special conditions of the West Indies. By this constructive co-operation with the University of London, the College will be enabled more quickly to work out the appropriate form which the local degrees should take when independent university status is achieved.

In the financial sphere, steps are similarly being taken to give maximum freedom to the College. Without endowments, it is at present dependent for its capital needs on grants from the Imperial Government, and for its recurrent income on contributions from the seven local governments. Devices for avoiding the possible dangers of this dependence, which have proved effective in the United Kingdom, have been adopted. The capital voted for the College under the Colonial Development and Welfare Act may amount to £1½ million, and is administered on the advice of a Colonial University Grants Committee predominantly academic in its composition. The local contributions are given as block grants, not earmarked in details, and as soon as the recurrent needs of the College can be more accurately forecast, they are likely to be given for three- or five-year periods at a time on the model of the quinquennial grant system for the universities of Great Britain.

The general plans for the College were sketched in the report of the Committee under Sir James Irvine which made an extensive tour of the Caribbean in 1944. The Committee recommended that the College should be unitary, residential and located in Jamaica. Although some of the seven territories must have been disappointed that they were not to be hosts to the College, there has been the fullest support from all, and the College is emerging as one of the first 'federal' institutions in the British West Indies. Student admissions are made not on a territorial quota basis but by competition; scholarships and the payment by the College of return passages to Jamaica ensure that candidates are not at a disadvantage through poverty or residence in an island remote from Jamaica. Jamaica has responded generously to its obligations as host to this West Indian institution by presenting a superb site of nearly 700 acres lying between the Blue Mountains and Long Mountain, six miles from Kingston, and by undertaking to meet a substantial part of the cost of an entirely new hospital which is being built on the site as the teaching hospital for the College medical school.

The inter-territoriality of the College has been emphasized by the work of its Department of Extra-Mural Studies, which began shortly before the internal teaching. Six of the seven full-time resident tutors have already taken up their duties in the territories to which they have been assigned; training courses for part-time tutors have been conducted by a specialist lent by the Oxford Extra-Mural Delegacy; and for the twenty-six classes in Jamaica in the autumn term of 1948 there were 1,200 students enrolled.

On the College site in Jamaica there is an extensive hutted camp, some parts of which have been adapted into temporary laboratories, halls of residence, library, students' union and staff accommodation. Designs for the permanent College and Hospital buildings by the architects, Messrs. Norman and Dawbarn, are well advanced, and it is expected that the contractors will begin work on the site within a few months. The availability of the temporary huts has made it possible for teaching to begin on a small scale; thirty-two students, including nine women, were admitted to the Faculty of Medicine in October 1948. A similar number will be admitted for the session 1949–50, together with about twenty-five students in the Faculty of Science. The Faculty of Arts will open in 1950 or 1951, depending on the progress of the permanent buildings.

The progressive stages in the starting of teaching has dictated the programme of staff appointments. The principal, Dr. T. W. J. Taylor, the director of extra-mural studies, Mr. Philip Sherlock, and the registrar, Mr. H. W. Springer, were appointed in 1946–47, the librarian, Mr. Harold Holdsworth, formerly of the Universities of Leeds and Cape Town, in 1948. The professor of botany, Dr. G. F. Asprey (formerly of the University of Aberdeen), the professor of zoology, Dr. Norman Millott (formerly of the University of Manchester), the professor of chemistry, Mr. C. H. Hassall (formerly of the University of Otago, New Zealand, and a research student at Cambridge), and the senior lecturer in physics, Mr. F. H. Bowen, took up their appointments early in 1948. Dr. W. F. Harper (London Hospital Medical College, University of London) has recently been appointed to the chair of anatomy, and Dr. I. F. Mackay (University of Durham) to the chair of physiology. Junior appointments have been made from the United Kingdom, Canada, South Africa and New Zealand. Of the twenty members of staff already appointed, eight are West Indians.

The importance attached by the College to the development of research is illustrated by the fact that it has already established one of its institutes, that for economic and social research, with Dr. H. D. Huggins as director. Undergraduate teaching in the social sciences may have to wait until the work of the Institute has begun to systematize the relevant data, to define some of the trends and problems of economic and social developments in the Caribbean, and to prepare the way for publications and other teaching material.

The University College of the West Indies faces many problems, such as its need for further funds and endowments and the task of building up its library resources at a time of famine in books; but the speed and efficiency with which it has developed in its first two years augur well for its further progress.

BUILDING RESEARCH IN GREAT BRITAIN

THE work carried out at the Building Research Station under the direction of the Building Research Board is well known to all those interested in the design and construction of civil engineering works of every kind and size, and the appearance of the first report of the Board* after the interruption caused by the War is very welcome.

The report covers the period 1940–45, and is divided into two parts, the first of which deals with the normal programme of research in progress in 1945. The second gives an account of the work carried out at the Building Research Station during the War, but contains much information capable of more general application. Finally, there is a classified list of technical publications by the Board and by members of the staff of the Station, which provides a useful guide to current literature. The field covered by the report is very wide, and the space devoted to each aspect of research is necessarily brief; but enough information is given to make clear the method of research and the results obtained.

The first section of the main body of the report deals with investigations into structural materials. The Station has collaborated in a technical survey of the brick-making industry, the testing programme for which was completed in 1945. Work on cement and concrete has dealt with the suitability of different types of limestone aggregates for roads, and with various light-weight concretes. Methods of steam curing have also been studied, and a programme of tests has been carried out at a factory making precast concrete products, to examine the degree of control of quality attainable. Methods which have been developed for determining the specific surface of cements by measurement of air permeability or by nitrogen absorption are likely to be applicable to many other fine powders, and have already been used for some industrial materials.

Perhaps the most generally interesting part of the Station's work is that dealing with the design of domestic buildings. Here the investigation falls into two parts, the first dealing with structural tests on non-traditional methods of construction, and the second with heat insulation, lighting, plumbing and ventilation. The experimental work was carried out on complete houses built for the purpose on land adjacent to the Station. These were then let to tenants whose daily experiences will provide a check on the conclusions reached experimentally. This work is to be continued and extended. Before leaving the subject of house construction, mention must be made of the committees set up by the Ministry of Works to study various aspects of post-war building. The Station was responsible for five of these committees, and provided assistance to others.

Another major investigation is that which started in conjunction with the Ministry of War Transport into the behaviour under load of composite bridge deck systems. The approach to this problem is of interest as indicating the systematic methods adopted by the Station when dealing with complex practical problems. The mathematical analysis is complicated and lengthy, and a series of full-scale tests to cover the whole field is obviously impracticable. The analysis will therefore be accompanied by a number of tests on small models, and the results from these will be compared with those obtained from a few larger models and from actual bridges, thus indicating whether any special conditions of restraint which occur in actual structures have been left out of consideration in the laboratory tests.

Other tests made on existing bridges to determine their suitability for the heavy traffic of war-time showed that many old bridges could safely carry a load of two or three times their 'safe load' as estimated by the usual methods. It was also found that in no case did the dynamic stress caused by a travelling load exceed by more than 30 per cent that produced by the same load at rest.

In connexion with these and other tests, much work has been done on the development and use of the acoustic strain-gauge and the wire-resistance strain-gauge. The acoustic gauge has been found to be particularly valuable both for field and laboratory work, and a method of measuring dynamic strains with it has been worked out. The description of the mobile instrument laboratory is of interest.

Work on soil mechanics has been directed mainly towards the general problem of house foundations. In particular, the cracking and settlement of dwelling houses on clay has been studied, and types of foundation design have been evolved which should prevent this trouble. A point of interest is the discovery that fast-growing trees, such as poplars and elms, may cause serious cracking at distances of as much as 50 ft., owing to the withdrawal of water by their roots.

Studies have also been made of the soil conditions on the sites of several large new civil engineering works. One of the most interesting is the comprehensive investigation carried out in connexion with the proposed Flood Protection Scheme in the Fenland.

The war-time work of the Station ranged from the examination of possible substitutes for scarce materials, such as the use of synthetic bauxite in the manufacture of aluminous cement, to model tests of the effect on structures of explosions in earth, air and water. One of the most spectacular was the destruction of the 1/20-scale model of the Mohne Dam. The success of the air attack made in 1943 upon the actual dam is well known.

A war-time development which will be of permanent value was the establishment of a sound basis for the design of reinforced concrete railway-sleepers. Measurements were made of the load transmitted to the sleeper during the passage of the train, using a robust and compact weighing-device, which, after removal of a chair, could be placed between the rail and sleeper without disturbing the foundation of the tracks. The distribution of pressure under the sleeper was measured by placing between it and the ballast a 'ball sandwich', composed of two steel plates between which were 150 or more hardened steel balls.

---

* Department of Scientific and Industrial Research. Report of the Building Research Board, with a Report of the Director of Building Research for the Years 1940–1945. Pp. viii+112. (London: H.M. Stationery Office, 1948.) 3s. 6d. net.

By measuring the indentations made by these, the load distribution could be determined.

The risk of fire is present both in peace and war, and has been studied by the Station from several points of view. The effect of heat on the strength of concrete and other structural materials has been examined. Tests have been developed to evaluate the degree to which different wall-coverings contribute to or retard the rapid spread of fire. The principles of lay-out to prevent the spread of fire by radiation between buildings have been worked out.

It has only been possible to refer to the more important items discussed in the report; but it will be seen that the range covered includes something of interest to anyone concerned with civil engineering construction. It is satisfactory to learn from the introductory report of the Board that the importance of the Station's work has been recognized by the recruitment of additional staff and the provision of further facilities for research.

MOON ECHOES AND PENETRATION OF THE IONOSPHERE

By F. J. KERR, C. A. SHAIN
AND
C. S. HIGGINS

Division of Radiophysics, Council for Scientific and Industrial Research, Australia

NORMAL ionospheric sounding technique can provide information on only the lower portion of the *F*-region, since waves capable of reaching beyond the level of maximum ionization are not returned to earth by any processes occurring within the ionosphere itself.

The reception of solar and cosmic radio noise at the earth's surface demonstrates that radio energy of sufficiently high frequency can penetrate the ionosphere, but unexpected ionospheric effects are sometimes found in records of 60 Mc./s. solar noise near sunrise. For a study of transmission right through the ionosphere, a signal from a controlled source is to be preferred to the highly variable emissions from the sun. It was thought that signals reflected from the moon might be used in this way for investigation of the ionosphere, and a series of exploratory tests was therefore undertaken.

Moon echoes were first obtained by the U.S. Army Signal Corps[1] and by Bay[2] early in 1946, in the metre wave-length region. The American observers reported large amplitude variations, which may have been due to ionospheric effects. For a specific study of the ionosphere it is desirable to work at lower frequencies, and it has been possible to use facilities already available in Australia for preliminary tests at these frequencies.

The results obtained to date may be summarized briefly as follow:

(1) Echoes from the moon have been obtained on thirteen out of fifteen attempts.

(2) The amplitude of the echoes was sometimes of the order expected on theoretical grounds, but more commonly it was considerably less.

(3) As the moon rose, echoes could not be obtained until the moon's angle of elevation was higher than was expected from calculations based on vertical-incidence ionospheric soundings.

(4) Analysis of 20 Mc./s. solar noise also shows ionospheric effects, with the significant difference that solar noise energy has been received at lower elevations of the sun than expected.

Experimental Arrangements

On several days each month, the moon passes through aerial beams used by the high-frequency broadcasting station Radio Australia for regular transmissions to the United States and Canada. This station is located in Shepparton, Victoria. With the co-operation of the Postmaster-General's Department, arrangements have been made for the use of a transmitter at this station when it is not required for broadcasting. The transmitter is pulsed by land-line from the Radiophysics Laboratory receiving station at Hornsby, New South Wales, 380 miles away. The electrical characteristics of the system used in the preliminary tests are summarized below.

Transmitter: *VLC*9, 17·84 Mc./s., 50 kW. output, or *VLB*5, 21·54 Mc./s., 70 kW. output.

Receiver: R.C.A. type *AR*88 communications receiver, with the band-width adjusted to 70 c./s. The stability with regulated supplies was such that slight retuning was necessary every 10–15 min.

Transmitting aerial: 16-element broadside array, with maximum of beam at 63° azimuth, 9° elevation, and first minimum in vertical plane at 23½°. Gain over an isotropic radiator, 22 db.

Receiving aerial: Rhombic aerial system, directed towards the region of the sky illuminated by the transmitting aerial. Beam steerable over a limited sector in the horizontal plane. Calculated gain over an isotropic radiator is 17 db. at 17·84 Mc./s.

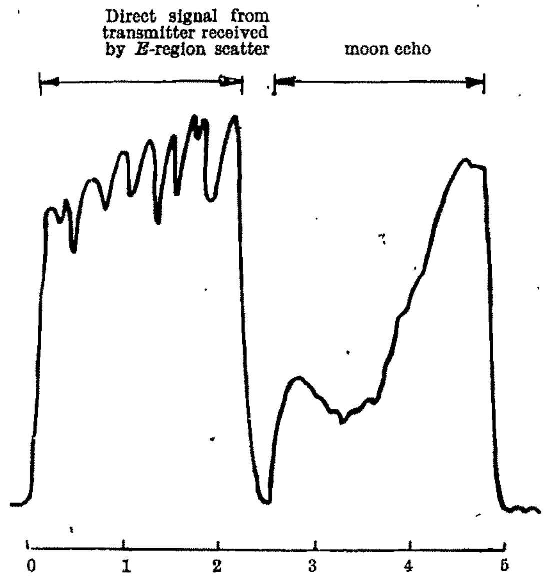
Display: (*a*) Long-persistence cathode-ray tube, and photographic recording. (*b*) Loudspeaker, using the beat-frequency oscillator of the receiver. The aural method was the more sensitive for detection of weak echoes.

Keying procedure: The most frequently used keying signals were: (*a*) A group of three ¼-sec. pulses (for identification of weak echoes). (*b*) A single pulse 2·2 sec. long (for studying short-period amplitude variations of the echo, which began to appear 2·6 sec. after the start of the transmitted pulse). The pulse repetition period was 6 sec.

Owing to the use of fixed aerials, observations are possible only when the moon is within the beam of the aerials, ionospheric conditions are suitable, and 'Radio Australia' is not required for broadcasting. The moon passes through the aerial beam on several successive days for two periods each month, at times related to sidereal time and hence varying with respect to solar time. The transmitters are available only during 0230–0530, 0930–1230 Eastern Australian Standard Time. In the latter period, the critical frequency of the F_2-region is usually too high for penetration to be possible. Hence the working time of the system is restricted to days when the moon is in the required part of the sky between 0230 and 0530, that is, to about twenty days in a year.

Echo Characteristics

Observations have been made in the 0230–0530 period on thirteen days, moon echoes being received on twelve of these for an average time of forty minutes. The less suitable 0930–1230 period was used only on two magnetically disturbed days, on one of which echoes were received.



Tracing of photograph showing typical amplitude variation of moon echo during a single 2·2-second pulse. The small fluctuations on the echo trace represent cosmic noise (I.F. band-width = 70 c./s., video band-width = 6 c./s.)

The echoes have shown considerable amplitude variation. First, their strength was found to be much less on some nights than on others. The maximum amplitudes for the various runs, after correction for aerial performance at the angles concerned, showed a variation of more than 20 db., considerably greater than the experimental uncertainty.

Secondly, within a single test the mean amplitude taken over several minutes varied widely. This type of variation showed periods of 5–20 min. For example, on one occasion the echoes were strong enough to overload the receiver during the signal peaks for about 10 min., and then the intensity fell to a barely audible level for a time. Observations normally began shortly after moonrise, echoes being first received when the moon had passed out of the '*F*-region shadow'. The first appearance of the echoes was usually fairly sudden. From the accepted picture of the ionosphere, it might be thought that once echoes had been detected the amplitude would then depend mainly on the polar diagram of the aerial, as the moon elevation increased. In some of the tests the mean amplitude of the echoes varied in this way, but in most cases large amplitude variations of the type mentioned above were superimposed on the variation due to the aerial. On some occasions the echoes were lost completely after a short time, although the moon was still in the aerial beam; on others they faded in and out several times during the period of observation. A striking example of this occurred on March 14 during an ionospheric disturbance. On this occasion moon echoes were received for 23 min., and then lost for 30 min. before being detected again just as the moon was leaving the aerial beam.

Thirdly, considerable short-period fading has been observed. Using the three-pulse system (quarter-second pulses a half-second apart), it was quite common to receive only one or two echoes out of the group of three. An example of a record obtained with a 2·2-sec. pulse and showing a short-period fading is given in the accompanying figure. This fading with periods of less than a second is not unlike that observed in signals reflected from the ionosphere, and so may be mainly ionospheric in origin.

Absolute Amplitude of Echoes

The echo cross-section of a large body is equal to the product of the projected area, the mean reflexion coefficient of the surface, and the directivity of the reflected energy in the direction of the transmitter. The reflexion coefficient depends on the dielectric constant, and the directivity on the shape and roughness of the surface. The strength of the echo from the moon was calculated from the standard radar equation, with reasonable assumptions concerning the reflecting properties of the moon.

The noise background at these frequencies consists mainly of cosmic noise. For a fixed low-angle aerial system, the cosmic noise-level varies with sidereal time and with ionospheric conditions. The noise temperatures at the times of the various tests were of the order of 10,000–20,000° K.

The calculated echo-strength was 30 db. above 15,000° cosmic noise, taking the moon at the centre of the aerial beam and neglecting ionospheric effects. In four of the thirteen tests in which echoes were received the maximum observed echo intensity, with suitable allowance from the theoretical aerial diagram, was within ± 5 db. of the calculated level. This is within the uncertainty of measurements with the equipment used in the exploratory work. In the other nine tests the maximum echo-strength was less by amounts of up to 20 db. On no occasion has the echo intensity exceeded the calculated level by more than the experimental uncertainty.

It cannot yet be said whether the reductions in intensity and the long-period variations are due to ionospheric, lunar or inter-planetary causes. Grieg, Metzger and Waer[3] seek to account for the amplitude variations in the American moon-echo experiments in terms of the interference fading produced by echoes from two or three 'bounce points' on the moon. Such a mechanism could produce short-period fading, but it is scarcely likely that day-to-day variations could arise in this way. If the echo intensity from the moon were predominantly due to reflexion from a few areas with favourable aspect, the echo would at times be expected to rise well above the calculated value for a rough sphere. No such high intensities have been found. An ionospheric origin for the slow variations seems more likely. Simultaneous reception of moon echoes at two points on the earth would provide evidence about the source of the variations.

Doppler Shift

The frequency of the received echoes was about 50 c./s. higher than that of the transmitted signal, the difference being clearly audible in the loudspeaker as a change in the note produced by the beat-frequency oscillator of the receiver. When the echo was sufficiently strong, it was possible to beat the two frequencies together. The frequency shift arises mainly from the Doppler effect of the earth's rotation, with smaller contributions from the moon's radial velocity, phase changes in the ionosphere, and variations in the effective centre of reflexion on the moon. An analysis of the effects of the various factors suggests that precision determinations of the shift and its time variations could be used to yield new information on the *F*-region. New determinations of certain astronomical and geodetic quantities could

Table 1. *F*-Region penetration

Conditions for the transmitted ray at the times of first detection of moon echoes, compared with the theoretical limiting angles for reflexion from the *F*-region back to ground. Following convention, angles of elevation and emission are measured from the horizontal, and angle of incidence from the normal to the *F*-region

Date (1947)	Frequency (Mc./s.)	Time of first detection of echoes (150° E. time)	Angle of elevation of moon	Theoretical minimum angle of emission for penetration	Observed maximum angle of incidence on F_2 for penetration	Theoretical maximum angle of incidence on F_2 for penetration
Nov. 7	17·84	0355	16·7°	12·2°	66·6°	69·8°
8	21·54	0348	10·7	6·2	70·4	72·3
9	21·54	0407	9·2	0	71·1	73·6
10	17·84	0502	14·9	0	67·3	74·5
Dec. 6	21·54	0234	13·5	8·2	69·3	72·2
7	21·54	0238	9·3	8·0	71·5	72·1

also be obtained, but only under very favourable ionospheric conditions.

Penetration Angles

A study has been made of the conditions under which the ionosphere is first penetrated, as the moon rises. The lowest angle at which echoes can be received is in the nature of a critical angle for the sensitivity employed. These minimum angles have been compared with the critical angles for the reflexion of waves from the *F*-region as calculated from the theoretical results of Appleton and Beynon[4].

Owing to the large distance between transmitter and receiver, the two directions of transmission through the ionosphere must be considered separately. *F*-region characteristics for the two estimated penetration points were derived from the vertical incidence data recorded every 10 min. at Canberra and Brisbane. From these were calculated the theoretical minimum angle of emission from the ground and maximum angle of incidence on the *F*-region for penetration. The theoretical minimum angle of emission was then compared with the elevation of the moon at the first detection of echoes, and the theoretical maximum angle of incidence compared with the angle of incidence on the *F*-region of a straight line from transmitter or receiver in the direction of the moon.

Under the conditions of the experiment, the elevation of the moon was about 5° less at Shepparton than at Hornsby. It is to be expected, therefore, that the elevation of the moon at Shepparton would determine the time at which echoes were first detected. As against this, a somewhat lower critical frequency was generally appropriate to transmission than to reception, in consequence of Shepparton's higher latitude. The difference in angles of elevation was found to be the more important effect, so that the limiting angles for echo-detection may be taken as those for the transmitted rays.

Table 1 presents the information on penetration conditions from the transmitter for the first six tests in which moon echoes were detected. It can be seen that echoes were not detected until the moon had risen well above the theoretical minimum angle of emission for penetration. Angle of incidence on the F_2-region is a more significant quantity than angle of emission. The table shows that the average difference between theoretical and observed limiting angles of incidence for penetration is 3°. This comparison refers to the angle of incidence on the F_2-region of a straight line from the transmitter to the moon. The angle of incidence of the penetrating ray will in general be less than this, as the ray path below the ionosphere will be closer to the normal than the ray path above, owing to the deviation which occurs in passing through a curved ionosphere. Under the conditions of the experiment, this deviation amounts to about 1–2° on current ionosphere theory. The effect is in such a direction as to increase the difference between the angle of incidence at which moon echoes might have been expected to appear and the angle at which they were first detected. Although the onset of the echoes was usually fairly abrupt, the maximum angle of incidence for penetration may not be as 'critical' as that for reflexion, and would possibly be reduced by the use of a more sensitive system.

Solar Noise

Information on penetration of the ionosphere is also obtainable from a study of solar noise. In the 20-Mc./s. region no general level of solar noise can be seen, but bursts often stand out from the cosmic noise background. Despite the sporadic nature of these bursts and their wide range of amplitude, useful results on penetration of the ionosphere can be obtained from the records. In contrast with the moon-echo results, it is not uncommon to receive solar noise bursts with the sun below the theoretical minimum elevation for penetration. Some examples are shown in Table 2. (The only theoretical results available on limiting angles for penetration are for the case of penetration from below.)

In comparing the evidence on ionospheric penetration obtained from moon echoes and from solar noise, two points must be remembered. First, in the echo experiments the limiting conditions were those for penetration of the ionosphere from below, whereas for solar noise, penetration was from above. The second difference is that the amplitude range for detectable solar noise bursts is greater than that for detectable moon echoes. Hence, if the cut-off at the *F*-region shadow were not sharp, high-intensity solar noise bursts could be seen at lower elevations than is possible for moon echoes. Present evidence sug-

Table 2. Examples of reception of solar noise bursts with the sun below the theoretical *F*-region shadow angle, as calculated from vertical incidence data

Date	Frequency (Mc./s.)	Time of reception of burst from sun (150° E. time)	Angle of elevation of sun	Theoretical minimum elevation for reception of penetrating rays	Observed angle between straight line from sun to receiver and normal to lower side of F_2	Theoretical maximum angle between penetrating ray and normal to lower side of F_2
July 10, 1947	18·3	1039	30·8°	37·2°	55·9°	50·2°
July 16, 1947	18·3	0938	24·9	31·5	61·0	55·3
April 16, 1948	18·3	1526	23·6	37·4	62·2	50·2

gests, however, that the cut-off is fairly abrupt, leading to the conclusion that transmission through the ionosphere in the two directions, from below and from above, appears to be different. Such lack of reciprocity could arise from the effect of the earth's magnetic field.

The work described in this paper is part of the research programme of the Division of Radiophysics, Council for Scientific and Industrial Research, Commonwealth of Australia.

OBITUARIES

Dr. F. H. A. Marshall, C.B.E., F.R.S.

Born at High Wycombe on July 11, 1878, Francis Hugh Adam Marshall died suddenly after an operation in a Cambridge nursing home on February 5. He was the younger son of Thomas Marshall, and was educated at St. Mark's School, Windsor, and privately. After a short time at University College, London, he went up to Christ's College, Cambridge, in 1896 and took the Natural Sciences Tripos. Inspired by the work of Walter Heape in Cambridge on sex physiology, he then accepted an invitation to work in Edinburgh with Prof. Cossar Ewart, who at that time was conducting his well-known experiments on telegony in farm animals at Penicuik. Here he started his research career and worked in conjunction also with the distinguished group of research physiologists centred around Sir Edward Sharpey Shafer. During this time he published many valuable papers on the œstrous cycle in the sheep (1903), the ferret (1904) and the dog (1905); but perhaps one of the most important was that on "The Ovary as an Organ of Internal Secretion", for it led to large developments in this field later. The University of Edinburgh honoured him with a D.Sc. and later with an LL.D. degree, and he was elected a fellow of the Royal Society of Edinburgh.

In 1908 Marshall returned to Cambridge, where he became lecturer in agricultural physiology in the newly formed School of Agriculture. He was also elected a fellow of Christ's College and lectured to medical students in the Department of Physiology on reproduction. It was during these years that he gathered the materials for and wrote his classical book on "The Physiology of Reproduction", which was first printed in 1910, a second edition appearing in 1922. This book appeared at an opportune time, for during that period research work was expanding rapidly in the United States and elsewhere, and the book, giving complete references to the literature on the subject, formed a background for the spectacular advances made later on the internal secretions of the reproductive organs, a subject to which much of Marshall's earlier work was devoted. At the time of his death he was busy with proofs of the third edition of this book, chapters for which had been contributed by many of his former pupils and associates whom he had inspired by his passionate devotion to his subject.

In the period of some thirty-five years during which he was lecturer, and afterwards reader, in agricultural physiology at Cambridge, he also laid the foundation for this subject as a basis for training in animal husbandry, and his book on the "Physiology of Farm Animals" is widely used and has run through several editions. In conjunction with the late Prof. T. B. Wood, the first director, he helped to develop the Institute of Animal Nutrition at the School of Agriculture, Cambridge, and became director himself for a short time after Wood's death. For his work for agricultural science he was made a C.B.E.

Marshall's literary talents were well developed and he wrote with a clarity and ease of style which held the attention of his readers. These powers he put to good use not only in his books but also as editor of the *Journal of Agricultural Science* and as a founder member of the editorial boards of the *British Journal of Experimental Biology* and the *Journal of Endocrinology*.

In 1920 he was elected a fellow of the Royal Society and served on the Council from 1933 until 1935. In the following year he delivered the Croonian Lecture on "Sexual Periodicity and the Causes which Determine it", in which he stressed the exteroceptive factors, especially of light, a subject on which he did much experimental work in his later years. He was awarded a Royal Medal in 1940.

At Cambridge Marshall played his part, too, in academic affairs, becoming tutor, dean and finally, in 1940, vice-master of Christ's College. He was a proctor during 1911–12 and afterwards served on the Council of the Senate. His kindly and gentle manner endeared him to his students and to the many aspiring research workers who came to seek his advice from far and wide. John Hammond

Prof. L. Farkas

The death of Ladislas Farkas, at the age of forty-four, removes from our midst a relatively young physical chemist of singular charm and undoubted ability.

Ladislas Farkas was the younger son of a Hungarian pharmacist living at Dunaszerdahely, and, like his elder brother, revealed a particular aptitude for physical chemistry. He attended the Technische Hochschule in Berlin, and then worked with Prof. Fritz Haber at the Kaiser Wilhelm Institut in Berlin-Dahlem at the period when the possible participation of atoms and radicals in chemical reactions had been recognized and demanded intensive investigation. His work here was so effective that he was promoted to 'assistant'. As the Nazi regime in Germany became more definitive, he found his position becoming more difficult, and he emigrated to work in the Department of Colloid Science at the University of Cambridge.

Deuterium, at that time, was scarcely obtainable in Britain, and its obvious utility, on account of the mass and zero point energy differences, in throwing light on the detailed mechanism of homogeneous, heterogeneous and catalytic reactions, suggested a promising field for inquiry. Farkas prepared deuterium compounds by the orthodox electrolytic and diffusion processes, and in addition elaborated a number of ingenious partition and chemical methods for its separation. The results of the investigation of a number of chemical and catalytic reactions, in which hydrogen and hydrogen-containing compounds were replaced by deuterium, were presented in a series of papers. His experimental work was characterized by elegance in design and execution, while his theoretical insight, already appreciated by Haber, was confirmed by his British co-workers.

Before the Second World War, when the Hebrew University of Jerusalem was undergoing extension, Farkas, at the request of Dr. Ch. Weizmann, joined the staff there and was appointed professor of physical chemistry in 1936, a post which he held at his death. During the last ten years he was particularly active in training young chemists in Israel. Early in 1942, the Palestine War Supply Board set up a scientific advisory committee to co-operate with the Middle East Supply Centre in Cairo, and Farkas became its scientific secretary. He developed methods for the local production of many important chemicals such as ethyl chloride, ethylene bromide and vitamin D.

He took an active part in the exploitation of the Dead Sea minerals, particularly the recovery and utilization of bromine.

At the end of December Farkas left Jerusalem for the United States to purchase scientific equipment, and on this journey he was the victim of an aeroplane crash in the vicinity of Rome. ERIC K. RIDEAL

WE regret to announce the following deaths:

Dr. Tenney L. Davis, emeritus professor of organic chemistry in the Massachusetts Institute of Technology, and editor-in-chief of *Chymia*, an annual publication devoted to historical chemistry, on January 25, aged fifty-nine.

Prof. T. S. Patterson, Gardiner professor of organic chemistry in the University of Glasgow, on February 14, aged seventy-six.

NEWS and VIEWS

Department of Scientific and Industrial Research: Sir Edward Appleton, G.B.E., K.C.B., F.R.S.

THE appointment of Sir Edward Appleton to be principal and vice-chancellor of the University of Edinburgh was announced in November last, and he will be taking up his new duties there in May. Sir Edward became secretary of the Department of Scientific and Industrial Research in February 1939, after a brilliant university career, during which he conducted his classical researches on the transmission of radio waves which led to the award of the Nobel Prize for Physics in 1947 (see *Nature*, November 22, 1947, p. 703). During the ten years he has been with the Department of Scientific and Industrial Research, Sir Edward has devoted all his energy to its interests and purposes. These are broadly: first, to seek scientific truth by carrying out research in the Department's establishments and by encouraging programmes of research in other appropriate places; and secondly, to foster the application of scientific knowledge for the benefit of the community. This period of service has included the arduous war years during which the duties and responsibilities of the head of the Department were particularly onerous and of vital importance to the nation. As an administrator, Sir Edward has come to be respected by all the staff who worked under him; as the Civil servant who represented the Government in all branches of science, except medicine, agriculture and fisheries, he has commanded the attention and appreciation of the whole of Britain. His wisdom, shrewdness and gentle, but persuasive, drive have made him much sought after as chairman of national committees of all types, whether these were concerned with scientific or technical matters or with the practical details of staffs and their organisation. Throughout his decade of Government service, Sir Edward has succeeded in maintaining a close and active interest in the field of radio science which he has made his own and for which he has an international reputation. There is little doubt that, while in his new position he will naturally be mainly concerned with university administration, he will find opportunities to continue his favourite line of research work.

Sir Ben Lockspeiser

SIR BEN LOCKSPEISER, who succeeds Sir Edward Appleton as secretary of the Department of Scientific and Industrial Research, was born in 1891. He was educated at the Grocers' School, London, and Sidney Sussex College, Cambridge. He served in the First World War, taking part in the Gallipoli Campaign. Invalided home, he worked under Prof. A. V. Hill on problems relating to fuses. His association with aeronautics started in 1920, when he went to the Royal Aircraft Establishment, Farnborough. He was at first engaged in research on crystal structures with Dr. A. A. Griffith; later he worked on aerodynamics and instrument design. He made valuable contributions to the theory of aircraft flutter and to the development of a chemical method of de-icing. He was placed in charge of the Air Defence Section at the Royal Aircraft Establishment in 1937, and it was perhaps in this that his best work, most of it secret, was done. He was transferred to the Ministry of Aircraft Production to take charge of armament research, being made assistant director in 1939 and deputy director in 1941; he became director of scientific research in succession to Dr. D. R. Pye in 1943, and director general in 1945. When the Ministry of Supply took over the responsibilities of the Ministry of Aircraft Production for aircraft, the need for a man of science to co-ordinate the scientific investigations of the whole Ministry was apparent, and Sir Ben was appointed as chief scientist to take over this work. Throughout his career Sir Ben has taken a strong interest in the status of scientific workers in the Civil Service; much of the improvement in conditions of service that has been achieved is due to his untiring efforts.

Physiology at University College, London: Prof. C. Lovatt Evans, F.R.S.

PROF. CHARLES LOVATT EVANS is retiring at the end of the present session from the Jodrell chair of physiology at University College, London, which he has occupied since 1926. He was originally a student and is now an honorary LL.D. of the University of Birmingham. He then went to University College as Sharpey Scholar in Starling's laboratory and qualified in medicine at University College Hospital. As a fellow of the College, as professor and as dean of the Faculty of Medical Sciences, he has spent a large part of his active life in the place. As a member of the Medical Research Council, of the council of the Royal Society (vice-president), of the council of the Royal Veterinary College and of many other bodies, as an experienced examiner at home and overseas, he has made many important contributions not only to original knowledge but also to the structure and organisation of medical, dental and veterinary science and education. During both World Wars his skill in physiological experiment found valuable full-time application to chemical warfare and personnel research. But Starling's laboratory and Starling's inspiration, as he would proudly acknowledge, have made University College his real home. He and Mrs. Lovatt Evans will be sorely missed.

Lovatt Evans is a physiologist of the kind, now becoming rare, with a wide and critical knowledge of the whole field of human physiology. An excellent chairman and lecturer, a wise and understanding colleague with familiar contacts with physiologists the world over, his help and advice have been sought, and will continue to be sought, by those who have problems to solve, gaps of knowledge to make good —or posts to fill. One of his most important services to physiology has been in keeping alive and up to date Starling's "Principles of Human Physiology", an immense and continuing labour to which he has added the authorship or editorship of other books and monographs. The admirable performance of this task depended on, and perhaps added to, the breadth of his knowledge. Lovatt Evans, although retiring this year, is young in mind and activity, and physiologists will expect him to continue as busy as ever in the service of physiology.

Lovatt Evans's own original work has been largely concerned with the circulatory system : heart, lungs, blood, oxidation, frequently with a bias towards the metabolic and chemical side (his early love was chemistry). But among a wide range of interests are also numbered liver function, sugar metabolism, blood *p*H, lactic acid, adrenalin, etc. A suggestion he once made, probably forgotten by him, based on his knowledge of plain muscle, fired off an important train of research on the function of potassium in striated muscle and thence in non-medullated nerve. Some of the best things start, apparently casually, by suggestions of that kind, and Lovatt Evans's wide knowledge must have been responsible for many; his pupils and his friends owe much to him and them.

Dr. G. L. Brown, C.B.E., F.R.S.

Dr. G. L. Brown, who has been appointed to succeed Prof. Lovatt Evans, has been a member of the scientific staff of the Medical Research Council for the last fourteen years. Dr. Brown was a student at the University of Manchester, where he graduated in medicine in 1927, having taken a higher degree in physiology during his course of study. He left Manchester to become demonstrator and later lecturer in physiology under the late Prof. McSwiney at Leeds, where his researches were concerned with the motor innervation of the stomach. When Dr. Brown went to the National Institute for Medical Research in 1934, he joined in the programme of work in Sir Henry Dale's laboratory on the chemical transmission of nerve impulses ; to this work he made major contributions, especially in connexion with the role of acetylcholine in the conduction of impulses through sympathetic ganglia and from motor nerves to skeletal muscle. Since then he has much extended his researches in neurophysiology with full application and development of modern electrical methods ; the results of his work are important not only for their scientific interest but also for their clinical applications. During the Second World War, Dr. Brown gave distinguished service, as secretary of the Royal Naval Personnel Research Committee, both by organising and directly stimulating researches on conditions affecting the efficiency of naval personnel. The chair at University College will thus be occupied by a man who has established himself as a leader in physiology, and who will undoubtedly uphold the great traditions of the Laboratory of which he will have charge.

Prof. Solly Zuckerman, C.B., F.R.S.

The Lord President of the Council has announced that Prof. Solly Zuckerman, a member of the Advisory Council on Scientific Policy and of the Committee on Industrial Productivity, has been appointed deputy chairman of both bodies. The appointment, it is stated, will help to relieve the burden on the chairman, Sir Henry Tizard, who is also chairman of the Defence Research Policy Committee. Prof. Zuckerman will continue as chairman of the panel on imports and as professor of anatomy in the University of Birmingham.

Operational Research in Industry

In reply to a question asked in the House of Commons on January 19 on operational research in industry, the Lord President of the Council, Mr. Herbert Morrison, stated that it is the policy of the Government "to encourage all scientific activities which contribute to increasing the productivity and efficiency of industry. Operational research . . . is a term given in the recent war to the use of the scientific method for obtaining data on which executive decisions can be based. It has been employed by progressive firms in many industries for a number of years ; . . . there is certainly room for more of it. I have had a full report on its possibilities from a Panel of the Committee on Industrial Productivity. Several of the co-operative research associations, in particular the Cotton Research Association, the Iron and Steel Research Association and the Boot, Shoe and Allied Trades Research Association are doing well with it; and with the general expansion of facilities since the War, other research associations are already carrying out, or are planning, similar work." Mr. Morrison added that the Departments concerned will extend every encouragement to firms anxious to develop operational research within their respective organisations.

Submarine Geology : New French Annual

Oceanographers, who have long had good cause to be grateful to two well-known American institutions for their volume of "Collected Reprints" distributed each year, will welcome the recent institution of a comparable practice in France. It is manifestly impossible for individuals, and practicable only for a few major libraries, to maintain subscriptions and exchanges adequate to ensure the receipt of anything like all the important oceanographical papers which appear in the course of a year ; a serious difficulty resides, of course, in the fact that so many organs of publication are concerned. This latter point is evident on scanning a new volume just received, *Travaux du Laboratoire de Géologie Sous-Marine*, vol. 1 (1947). This is produced by the École Pratique des Hautes Études, 1 Rue Victor-Cousin, Paris 5e, under the superintendence of the director, Jacques Bourcart. It contains fifteen papers ; five are by Dr. Bourcart himself, of which three are on the sediments of the French continental shelf, one on sedimentation in the English Channel, and the other on the geology of the 'Iles Atlantides'. A paper by B. Brajnikov on the origin of the alluvial deposits of the Seine estuary is followed by a series of three by Prof. A. Cailleux, of which one discusses criteria for distinguishing between marine and fluviatile gravels. Dr. Claude Francis-Bœuf, who is the author of five of the remaining papers, is well known for papers already published on the processes involved in estuarial sedimentation—a topic of great present-day importance. He discusses the physicochemical factors of estuarial waters in connexion with the tropisms which affect eel migrations; sedimentation in estuaries; the oxygen content of fluviomarine muds, and the production and consumption of oxygen in the topmost surface layer of the latter. The last paper, by V. Romanovsky, is on the elasticity of agar-agar gels. All the papers included are reprints from various publications; the practice of issuing annual fascicules of reprints in special branches of study is very valuable to those directly interested.

International Committee on Nomenclature of Ocean Bottom Features

The International Union of Geodesy and Geophysics re-established, at its Oslo meeting in August 1948, an International Committee on the Nomenclature of Ocean Bottom Features under the chairmanship of Dr. J. D. H. Wiseman, British Museum (Natural History). The other members of this Committee are: Vice-Admiral J. D. Nares (*secretary*), International Hydrographic Bureau, Monaco; Dr. K. O. Emery, United States; Prof. H. H. Hess, United States; Prof. Hans Pettersson, Sweden; and Prof. Ph. Kuenen, Holland. The terms of reference of the Committee are: "To endeavour to establish in co-operation with the chart-making authorities, mechanisms for the International agreement on the nomenclature of submarine topographical features, as well as considering methods of presentation of marine topographical data on bathymetrical charts".

In order to facilitate the work of this International Committee, a British National Committee has been established under the chairmanship of Dr. J. D. H. Wiseman, with the following members: Mr. C. D. Ovey (*secretary*), British Museum (Natural History); Dr. J. N. Carruthers, Admiralty; Dr. L. H. N. Cooper, Marine Biological Association of Great Britain, Plymouth; Mr. H. F. P. Herdman, "Discovery" Investigations; Prof. W. B. R. King, Sedgwick Museum, Cambridge; Lieut.-Colonel R. B. Seymour Sewell, Zoological Laboratory, Cambridge; and Mr. J. A. Steers, president of St. Catharine's College, Cambridge. Early consideration will be given by this Committee to the various physiographical features found at the bottom of the oceans, and at a later stage to nomenclature and the presentation of data on bathymetrical charts. The British Committee would welcome and carefully consider any individual contributions or suggestion, which should be addressed to its secretary, Mr. C. D. Ovey, British Museum (Natural History), Cromwell Road, London, S.W.7.

Maternal Mortality in India

Inquiries into the causes of maternal mortality in Bombay, Calcutta, Delhi and Madras show that the data published in the reports of public health departments are unreliable and do not give an accurate picture of the real situation. These inquiries have been collated by Dr. S. Pandit in a report of the Indian Research Fund Association (No. 17; June 1948), and show that figures obtained by special investigations are considerably in excess of the numbers recorded in the public health reports. According to the reports of the executive health officer of Bombay, for example, the maternal mortality-rate for the year 1937 was 4·4 per 1,000 live births, whereas the rate determined by Dr. J. Jhirad for the same period was 13·5 per 1,000 live births. A clearer picture of the incidence of maternal mortality and of the causes responsible for it could be obtained only when a better system of recording all vital occurrences and of certification of the causes of death become widely established throughout India.

A statistical review of the figures collected during the investigations emphasizes the need for developing health services for prenatal care, adequate domiciliary and institutional midwifery services and close co-operation among the different agencies responsible for them. The reports recommend provision of facilities for institutional treatment for abnormal midwifery and puerperal sepsis cases. It is suggested that medical men and midwives in maternity services should have knowledge of preventive aspects of maternal care and, wherever possible, services of health visitors should be employed for educational and follow-up work. As anæmia forms one of the main causes of maternal deaths in India, its diagnosis and early treatment during pregnancy is of vital importance, and special attention should be paid to this condition. To improve the maternal health programme a service providing correct information on maternal deaths should be maintained and research into all aspects of maternal health should be conducted.

Fertility of Scottish Women

The widely held belief that decline in fertility among women is directly related to the degree of urbanization which has taken place in a community is not borne out by investigations which have been made by R. S. Barclay and W. O. Kermack (*Proc. Roy. Soc. Edin.*, Section B, 43, Part 11, No. 9). Surveying the trends of fertility in various sections of the population of Scotland from 1860 onwards, they gave special attention to the comparison of urban and rural areas. Difficulties in assembling the statistics arose because of the alterations introduced from time to time in the basis of classification used by the Registrar-General; but these were overcome in various ways. The areas investigated were the four chief cities, Glasgow, Edinburgh, Dundee and Aberdeen, and two groups of counties, one typical of the Highlands (Sutherland, Ross and Cromarty, Inverness and Nairn), and the other typical of the Borders (Peebles, Selkirk, Roxburgh and Berwick).

The results show that the fall in fertility in Scotland set in at about the same time in both urban and rural areas and, broadly speaking, the trends have run closely parallel in these two sections of the community. The fall in the urban section was neither earlier nor more rapid than that in the rural section. Other interesting findings are that the trend of legitimate fertility in the Border group of four counties contrasts strikingly with the trend in the Highland group, the fall in fertility in the former having set in earlier and proceeded more rapidly, while the fall in legitimate fertility in Aberdeen appears to have set in about twenty years later than in the other three large cities of Scotland.

Bird-Ringing in South Africa

THE first ringing of South African migratory birds was made early in December 1948 when the Cape Bird Club, under the direction of Dr. G. J. Broekhuysen of the University of Cape Town, used specially designed nets to catch European waders on the mud flats at Muizenberg, and marked them with leg bands inscribed "Zoo-Pretoria". The ringing scheme is sponsored by the South African Ornithological Society and is being extended over the Western Province. The birds caught were weighed before marking and release. Little stints, avocets, Sandwich terns, curlew-sandpipers, stilts and other familiar British birds-of-passage and nesting birds are expected to figure prominently in the South African experiment, which will not only elucidate further details about the winter quarters of European waders, and shore birds, but also determine whether many of the birds found at the Cape remain in the Union throughout the year, or nest elsewhere in Africa. Certain species like the black-winged stilt not only migrate from European nesting haunts but also breed in parts of Africa.

For many years now migratory birds ringed in European nesting haunts have been recovered at winter haunts in Africa. Notable among these have been the European swallow, the house-martin, the common swift, the cuckoo, the nightjar, the red-backed shrike and the Sandwich tern and the white stork. More than a score of common swallows marked when nesting or as nestlings in the British Isles have been recovered in South Africa, and the Sandwich tern from Britain has been recovered in Natal.

Research at the University of Sydney

A COMMITTEE appointed by the vice-chancellor has prepared an interesting description of the original scientific work done at the University of Sydney during the years 1944 and 1945, so continuing the account set out in the previous publication for the years 1942–43. The report shows that, despite the absence of many members of staff on war service and the greater amount of teaching duties undertaken by those who remained at the University, much valuable work was carried out and a considerable number of young workers were trained to undertake research. Subjects of research are listed under the headings: art, law, medicine, science, engineering, veterinary science, agriculture, economics and social studies.

University of Leeds

THE Council of the University of Leeds has announced the receipt of the following gifts, among others: a sum of £200 given to Prof. S. Brodetsky by his friends on his retirement from the chair of applied mathematics and presented by him to the University for the establishment of a prize in mathematics; £1,500 given to the Inorganic and Physical Chemistry Department by the Royal Society for the development of a special Weissenberg goniometer.

The following appointments have been made: Dr. D. G. Christopherson, fellow and bursar of Magdalene College, Cambridge, to be professor of mechanical engineering from September 1, 1949, in succession to the late Prof. W. T. David; Mr. R. Holliday, to be senior lecturer in agriculture.

Royal Society Lectures for 1949

THE Croonian Lecture for 1949 will be delivered on June 30 by Dr. D. W. Bronk, foreign secretary of the National Academy of Sciences and chairman of the National Research Council of the United States. As director of the Johnson Institute for Medical Physics in the University of Pennsylvania, he has greatly influenced the development of biophysics, his special field of work being the physiology of the nervous system; his recent work has been on the oxygen consumption of the brain. The Croonian Lecture was founded by Dr. William Croone, one of the original fellows of the Royal Society, "for a lecture and illustrative experiment for the advancement of natural knowledge on local motion"; the first lecture was delivered in 1738.

The Bakerian Lecture for 1949 will be delivered on May 12 by Prof. H. Raistrick, professor of biochemistry in the University of London. This Lecture was founded by Mr. Henry Baker, "for a yearly oration or discourse by one of the Fellows on some part of natural history or experimental philosophy"; the first lecture was delivered in 1775.

The Wilkins Lecture for 1949 will be delivered on December 15 by Prof. E. N. da C. Andrade, Quain professor of physics in the University of London. The Wilkins Lecture on the history of science was founded in 1947 by Mr. J. D. Griffith Davies, a recent assistant secretary of the Society, who delivered the first lecture entitled "John Wilkins and the Royal Society" in 1948.

Goethe Bicentenary Lectures

A SERIES of six festival lectures in commemoration of the bicentenary of the birth of Goethe will be held at University College, London, under the auspices of the British Goethe Festival Society, beginning on March 3. The first lecture is by Prof. L. A. Willoughby, on "The Living Goethe". The remaining lectures are by Dr. G. P. Gooch, on "Goethe, the Liberal-Conservative" (March 10); Prof. F. Blume, "Goethe and Music" (March 17); Dr. Karl Wolff, speaking in German, on Goethe's religion (April 21); Prof. H. Friedmann, "Goethe's Morphology" (April 28); Mr. L. L. Whyte, "Goethe's Single View of Nature and Man" (May 5). The lectures are at 5.30 p.m. and are open to the public without fee or ticket.

First International Congress of Biochemistry

THE First International Congress of Biochemistry will be held in Cambridge during August 19–25, 1949. The Congress is under the presidency of Prof. A. C. Chibnall, and for the reading of papers and for discussion it is organised into twelve separate sections, each with its own chairman, as follows: animal nutrition and general metabolism, Sir Jack Drummond; microbiological chemistry (vacant through the recent death of Miss Marjory Stephenson); enzymes and tissue metabolism, Prof. R. A. Peters; proteins, Dr. K. Bailey; clinical biochemistry, Prof. E. J. King; structure and synthesis of biologically important substances, Prof. A. R. Todd; cytochemistry, Prof. J. N. Davidson; biological pigments: oxygen carriers and oxidizing catalysts, Prof. D. Keilin; hormones and steroids, Prof. F. G. Young; chemotherapy and immunochemistry, Sir Charles Harington; plant biochemistry, Dr. C. S. Hanes; industrial fermentations, Mr. H. J. Bunker. In addition to the meetings of the sections, there will be Congress lectures and visits to research stations and laboratories. The fee for membership of this Congress is £2. Applications and inquiries should be addressed to the Honorary Organiser, First International Congress of Biochemistry, 56 Victoria Street, London, S.W.1.

Conference in London on Prehistoric Homesteads

A Conference on "Prehistoric Houses and Farms, and Some Later Comparisons" will be held by the Prehistoric Society in collaboration with the University of London Institute of Archæology during April 22–24, 1949, at the latter's address at Inner Circle, Regent's Park, London, N.W.1. Admission to the Conference is free to members of the Society and of the Institute, and for all others the price of admission is 5*s*., inclusive for all days, tickets being obtainable at the door only. The honorary secretary of the Conference is Mr. T. G. E. Powell, Department of Prehistoric Archæology, University, Liverpool, 3.

Medical Research Council: Carcinogenic Action of Mineral Oils

The Medical Research Council has appointed the following to advise and assist in the prosecution of research on the carcinogenic action of mineral oils: Prof. T. Ferguson, professor of public health, University of Glasgow (*chairman*); Colonel S. J. M. Auld, chairman of Research Group No. 2, Institute of Petroleum; Prof. J. W. Cook, regius professor of chemistry, University of Glasgow; Prof. A. Haddow, professor of experimental pathology, University of London, and director of the Chester Beatty Research Institute, Royal Cancer Hospital, London; Dr. J. O. Irwin, senior research worker, Medical Research Council Statistical Research Unit, London School of Hygiene; Prof. J. R. Squire, professor of experimental pathology, University of Birmingham; Dr. D. L. Woodhouse, officer-in-charge, Cancer Research Laboratory, University of Birmingham; Dr. J. M. Rogan, Medical Research Council Headquarters Staff (*secretary*). In addition, the Ministries of Fuel and Power, Health, and Ministry of Labour and National Service, have nominated representatives who will attend meetings when matters of interest to these departments are likely to arise.

Royal Astronomical Society: Officers for 1949

At the annual general meeting of the Royal Astronomical Society held on February 11, Prof. W. M. Smart, regius professor of astronomy in the University of Glasgow, was elected president. The following were also elected officers of the Society: *Treasurer*, Sir Harold Spencer Jones; *Secretaries*, Prof. R. O. Redman and Dr. A. Hunter; *Foreign Secretary*, Prof. F. J. M. Stratton.

The Night Sky in March

Full moon occurs on March 14d. 19h. 03m., U.T., and new moon on March 29d. 15h. 11m. The following conjunctions with the moon take place: March 13d. 06h., Saturn 3° S.; March 23d. 14h., Jupiter 5° N.; March 28d. 05h., Mercury 0·7° N. Mercury rises 45 minutes before the sun at the beginning of the month and 20 minutes before sunrise at the middle of the month, and is unfavourably placed for observation. Venus is too close to the sun during March for favourable observation. Mars is in conjunction with the sun on March 17 and cannot be seen during the month. Jupiter rises at 5h. 04m., 4h. 17m. and 3h. 22m. at the beginning, middle and end of the month respectively, and can be observed low down during the early morning hours in the constellation of Sagittarius. Saturn, in the constellation of Leo Major, can be observed throughout most of the night, setting at 6h. 45m., 5h. 45m. and 4h. 45m. at the beginning, middle and end of the month respectively. Occultations of stars brighter than magnitude 6 are as follow: March 5d. 21h. 49·3m., δ Arie. (*D*); March 6d. 18h. 40·3m., 33 Taur. (*D*); March 8d. 20h. 21·8m., 136 Taur. (*D*); March 10d. 22h. 24·8m., ω Canc. (*D*). *D* refers to disappearance, and the latitude of Greenwich is assumed. Spring equinox commences on March 20d. 23h.

Announcements

The following elections have been made to the Paris Academy of Sciences: M. Constantin Dawidoff, to be *correspondant* for the Section of Anatomy and Zoology, in succession to the late Prof. Johan Hjort; M. André Donatien, to be *correspondant* for the Section of Rural Economy, in succession to the late M. D. Prianichnikov.

The following appointments in the University of Birmingham have been announced: Dr. F. Morgan, to be reader in chemical engineering; Mr. M. Shaw, to be Tube Investments Research Fellow in the Department of Engineering Production. The following have been appointed lecturers in the subjects as indicated: Dr. G. M. Burnett (chemistry); Dr. W. G. Overend (chemistry); Mr. D. A. Bell (electrical engineering); Mr. J. C. Henderson (electrical engineering).

The Council of the University of Sheffield has made the following appointments: Dr. Quentin H. Gibson, lecturer in physiology, to be senior lecturer in physiology; Frank A. Benson, lecturer in electrical engineering; Margaret Gunn, cancer research assistant (to work in the Department of Pathology under the auspices of the British Empire Cancer Campaign).

Dr. C. West has relinquished the post of superintendent of the Ditton Laboratory of the Department of Scientific and Industrial Research on transfer to the headquarters of the Director of Food Investigations, 20A Regent Street, Cambridge, for special duty. He is succeeded by Dr. R. G. Tomkins, of the Low Temperature Research Station, Cambridge. The Laboratory will continue to work mainly on problems of preserving fresh fruit and vegetables by refrigeration.

The trustees of the Ramsay Memorial Fellowships for Chemical Research invite applications before April 16 for these fellowships, one of which will be limited to candidates educated in Glasgow. The value of each fellowship will be £400 per annum, with a grant for research expenses not exceeding £100 per annum. Particulars can be obtained from the Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College, Gower Street, London, W.C.1.

The second 'chemical day' at Clausthal will be held, under the auspices of the Harz Section of the German Chemical Society in the British Zone, during March 4–5.

Errata.—In the account in *Nature* of December 25, p. 985, of the Nutrition Society's meeting on "Anti-vitamins", Dr. L. J. Harris was incorrectly reported to have stated that the active principle of 'Gammexane' is hexachlorobenzene; it should be, of course, the gamma isomer of benzene hexachloride (hexachloro*cyclo*hexane). The statement attributed to Dr. E. Kodicek that live yeast contains thiaminase is also incorrect.

Absorption of Star-Producing Radiation Under Ice

MEASUREMENTS of the absorption of the radiation responsible for the nuclear disintegrations observed in photographic emulsions have been made in the atmosphere and under lead. The star intensity I, at a depth h gm./cm.^{2} from the top of a medium, can be represented by

$$I = I_0 \exp(-h/l),$$

where l is the range of the star-producing radiation in gm./cm.^{2}.

Experimental ranges of 160 gm./cm.^{2} and 140 gm./cm.^{2} have been obtained in air by George[1] and Perkins[2] respectively. By considering the single tracks which accompany stars, and which in number he showed to be proportional to the number of stars, Perkins deduced a value of 320 gm./cm.^{2} for the range of the star-producing radiation in lead. He thus concluded that the stars are produced by unstable particles.

Considering the stars proper, George obtained a range of 310 gm./cm.^{2} in lead and suggested that the increased range in lead compared with that in air could be explained by the different atomic weights of the absorbers, instead of by their different densities. To distinguish between these two possibilities, we had already started an experiment to determine the absorption of the radiation under ice, which, although having a density approximately a thousand times that of air, has nearly the same atomic weight.

If we assume that the primaries have a cross-section for star-production proportional to the geometrical cross-section of the nucleus, we can calculate the expected ratio of the range in air to that in ice. Since the hydrogen in the ice is not disintegrated, the cross-section for star production depends only on the oxygen nuclei present. Hence we get

$$l_{\text{air}} : l_{\text{ice}} = 1 : 1{\cdot}16.$$

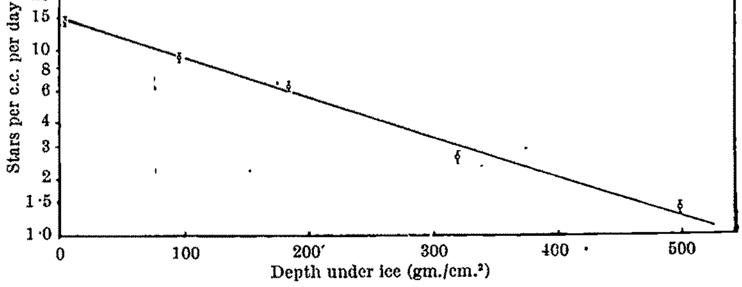
A calculation by George yields

$$l_{\text{air}} : l_{\text{lead}} = 1 : 2{\cdot}4,$$

which is in good agreement with the mean experimental ratio of 150 : 315 = 1 : 2·1.

On this hypothesis, we should expect a range in ice only slightly greater than that in air, whereas, if we suppose that the stars are produced by an unstable radiation, the absorption being proportional to mass, we find that the observed range in ice should be indistinguishable from that in lead.

Ilford *C*2 emulsions, 100 μ thick, coated on glass, were wrapped in black paper and packed in wax-coated cardboard boxes. These boxes were lowered, keeping the plates horizontal, into a narrow crevasse (about 10 cm. wide) in a glacier at the Jungfraujoch, height 3,650 m. Plates were thus exposed at the following depths below the surface of the ice for fifty days: 0 m., 1 m., 2 m., 3½ m. and 5½ m. By the end of the experiment the plates had been further covered by about 50 cm. of lightly packed snow. Taking an average value of 0·9 for the density of ice and allowing 5 gm./cm.^{2} for the snow coverage, we obtain the depths of exposure in gm./cm.^{2}. The experiment was commenced within one week of manufacture of the plates (four days were spent below 1,500 m., and three days below 200 ft. of rock at 3,650 m.) and the processing completed within four days of the termination of the experiment. We have not corrected our results for pre- or post-exposure.



Using a 4-mm. objective, the plates were scanned for stars at the rate of 1 sq. in. per day, and then re-scanned at half this speed. Using the results of both scannings, we are sure that not more than 1 per cent of the stars have been overlooked.

We have defined a star as having at least two prongs, one of which must have a range of more than 60 μ of emulsion, and we have only included those two-track stars which could definitely be distinguished from large-angle deflexions in single tracks. We have thus under-estimated the true number of two-track stars, but have included the certain ones in order to better our statistics. A significantly different result is not obtained by considering only stars with three or more prongs.

The number of stars per c.c. per day has been plotted on a logarithmic scale against the depth in gm./cm.^{2} of ice. The deviations shown are the calculated probable errors on the finite number of stars obtained.

Depth under ice in gm./cm.^{2}	5	95	185	320	500
No. of stars observed	138	102	91	84	78
Area of plates in cm.^{2}	19	22	29	64	110
Stars/c.c./day	14·3±0·8	9·1±0·6	6·3±0·4	2·6±0·2	1·4±0·1

The range of the star-producing radiation as calculated from the slope of the graph is 200 gm./cm.^{2}, which is 1·33 times the mean range (150 gm./cm.^{2}) in air. This is in fair agreement with the ratio calculated, assuming that the cross-section for star production is proportional to the geometric cross-section of the nucleus; and from the range of 200 gm./cm.^{2} we calculate an effective cross-section of 0·15 barns for an oxygen nucleus.

We thus conclude that the stars are produced by stable particles, their range depending on the atomic weight of the absorber. It may here be noted that the radiation responsible for the single tracks has a range of 200 gm./cm.^{2} in ice, thus confirming Perkins's earlier conclusions that the stars and single tracks are in equilibrium. This work is being reported fully elsewhere[3].

We should like to express our indebtedness to Prof. A. von Muralt and Dr. R. Stämpfli for providing facilities at the Jungfraujoch Scientific Station during the course of this experiment.

Adenosine Triphosphate and Muscular Contraction

It is commonly stated, on evidence obtained with muscle extracts, that the energy of muscular contraction is derived in the first instance from the breaking of the terminal energy-rich phosphate bond of adenosine triphosphate. Why not try to find out whether it really is, not in muscle extracts which cannot contract but in muscles which can ?

The total energy obtainable from this source, from the whole of the adenosine triphosphate present in muscle, is calculated to be about 0·05 calorie per gm. In the maximal contraction of a frog's muscle at 20° C., this would last only about 0·5 sec. Before then, however, according to current hypothesis, the restoration of the adenosine triphosphate at the expense of the energy of creatine phosphate breakdown (the 'Lohmann reaction') is well under way; the difficulty of resolving chemical events occurring so rapidly might very well be regarded as insuperable. But there are two easy ways around this obstacle: (i) to use a slower muscle; and (ii) to work at a lower temperature. The liberation of energy in toad's muscle during maintained contraction is only half as rapid as in frog's, in tortoise's only 1/10 to 1/20 as rapid; and its rate can be diminished about nine times by lowering the temperature to 0° C.

One cannot be sure how fast the adenosine triphosphate (if it *is* broken down in contraction) would be restored by the Lohmann reaction at 0° C. during maintained activity. Apart from such restoration, its breakdown in toad's muscle would be complete in 10 sec., in tortoise's in 50–100 sec. Probably in times of this order a balance would be reached between breakdown and restoration, at a level substantially different from that at rest. The slowness of the processes involved, particularly in tortoise's muscle at 0° C., should allow ample time for the necessary treatment preliminary to chemical analysis, and good resolution in time could probably be obtained. The experiment might allow a clear decision to be reached as to whether adenosine triphosphate is really concerned with the contractile process as such, or whether —like every other chemical change known to occur in muscle—it is part of the mechanism of recovery.

Prof. T. B. L. Webster recently provided an epigram to be posted in my laboratory: Ὑπόθεσις ἔλεγχους μὴ ἀποδεχομένη οὐκ ἐξοιστέα, which means that hypotheses should not be put forward that do not admit of test. The hypothesis that adenosine triphosphate breaks down during the contraction of a living muscle ought not to be left in that category, but only biochemists can remove it.

Meson Masses and the Principle of Reciprocity

In two previous letters, M. Born and H. S. Green have proposed a new theory of elementary particles and quantized fields and applied it to the case of mesons. We shall give some numerical results which follow from the theory.

There is an infinite number of particles predicted by this theory, the rest-masses of which are the square roots of the solutions of certain transcendental equations, namely,

$$\mathbf{L}_n^{(1)}(x) = 0, \tag{1}$$

where $\mathbf{L}_n^{(1)}(x)$ are the Laguerre polynomials of the first kind. The first of these were given in the first paper, and it is easy to calculate the following ones with the help of a well-known recurrence formula. We have solved the equations (1) and found the following values for their roots:

n	x				
1	2				
2	1·26	4·73			
3	0·93	3·31	7·75		
4	0·74	2·57	5·73	10·9	
5	0·53	2·11	4·61	8·40	14·26

These figures are connected with the masses in the following way: let a and b be the absolute length and momentum such that $ab = \hbar$. Then the wave equation for particles belonging to a given value x is

$$(p^2 - E^2 - xb^2)\,\psi = 0. \tag{2}$$

Hence one has for the mass

$$m = b\sqrt{x}/c. \tag{3}$$

Consider the first particle corresponding to $n = 1$ and replace b by $a/\hbar$, then

$$m = \hbar\sqrt{2}/ac. \tag{4}$$

Now we make the assumption which at the present state of the investigation cannot be justified from theoretical arguments but seems rather plausible, namely, that a is the classical radius of the electron, given by

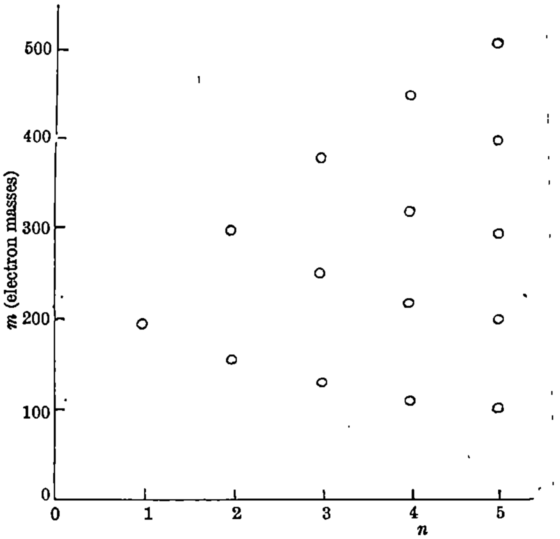
$$a = e^2/\mu c^2, \tag{5}$$

where μ is the mass of the electron. If this is substituted in (4) one obtains

$$\frac{m}{\mu} = \frac{\hbar c}{e^2}\sqrt{2} = 137\,.\,\sqrt{2} \simeq 194. \tag{6}$$

We venture the suggestion that this value of m is the mass of the most stable meson. Indeed, the experimental determinations of the mass of the mesons which are observed at sea-level, and are therefore presumably the most stable ones, is given by the Bristol workers as about 200 μ, in good agreement with our calculated value. (According to the report by J. A. Wheeler on the Pocono Conference, the value found at Berkeley is 192 μ.)

The accompanying figure gives the masses of the other mesons, based on the same assumption (5). One sees that the next most stable meson of higher mass has $m = 300\,\mu$, which corresponds very well to the observed π-mesons. The ratio of the two first calculated masses is 1·54, in good agreement with the results obtained in Bristol, while the Berkeley experiments are reported to give 1·32.



But there are many more less stable mesons predicted, and the spreading of the values obtained by different observers might be very well explained by the assumption that they had to do with different types of particles.

A preliminary investigation of particles with spin has shown that the rest-masses given by this theory are of the same order of magnitude except one, which is zero. Hence the observed small value of the mass of the electron must be of secondary origin, namely, a self-energy produced by the surrounding electromagnetic field. Investigations of this question are in progress.

Optical Sensitization of Lead Sulphide Layers made without Oxygen

Information regarding the preparation of photosensitive lead sulphide layers has already been published[1,2], the preparation involving the introduction of oxygen as an essential impurity. Sensitive layers have now been made without the use of oxygen by forming the lead sulphide layer by evaporation in sulphur vapour.

During the course of this work, it was found that if the layer was collected on a surface at a temperature of about 100° C., it was not normally photosensitive, but could be made so by prolonged illumination by visible light of high intensity, while the cell was maintained at a low temperature (90° K.). The photosensitivity (defined as the decrease, $\Delta R/R$, in cell resistance for unit incident intensity) was measured at a wave-length of 1·2 μ, using radiation of intensity small compared with that of the sensitizing light, which was shut off while measurements were being made.

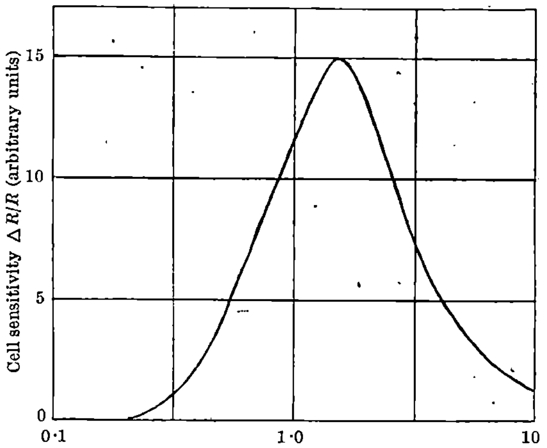

Fig. 1

The variation in cell sensitivity and dark conductivity during sensitization are shown in the figure, the time-scale being logarithmic. If at any time the sensitizing light is removed and the cell maintained at 90° K. in the dark, it returns slowly to its original condition. This process takes many hours at 90° K., but may be accelerated by warming slightly, suggesting that thermally metastable levels (that is, electron traps) are filled during sensitization. Sensitization at 77° K. proceeds more quickly than at 90° K., the subsequent decay proceeding more slowly, thus confirming the above hypothesis. Measurement of the thermal decay of the traps indicates that they have a depth[6] of about 0·3 eV.

The time taken to reach maximum sensitivity or a chosen value of the dark conductivity is inversely proportional to the sensitizing intensity, provided that this time is short compared with the mean decay time of the traps. The sensitivity and dark conductivity are thus a function of the product (sensitizing intensity × time), and it is found that the conductivity is described by the equation:

$$\sigma = \sigma_0 + c \log (I.t + 1),$$

where I is the sensitizing intensity in arbitrary units.

An equation of this type describes the number of electron traps filled on illumination of silver halide crystals[3] and zinc sulphide phosphors[4]. It seems

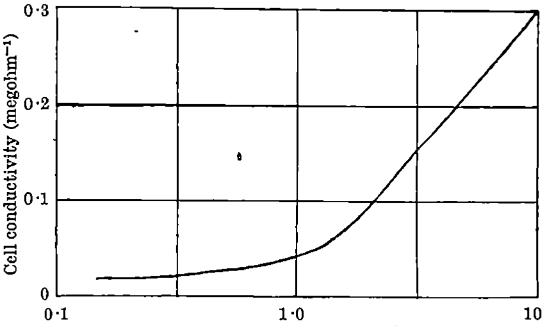

Fig. 2

reasonable to suppose, therefore, that the increase in dark conductivity is determined by the number of mobile positive holes left when the excited electrons are trapped. Thermo-electric power measurements confirmed that the conductivity was due to positive holes.

The sensitization spectrum was found to be very similar to the photoconductivity spectrum of free sulphur. In view of the conditions of preparation, it is likely that specks of free sulphur exist in the layer; and hence the sensitization process entails the raising of electrons from the filled band of the sulphur crystals into the conduction band, from which they are afterwards trapped.

There is no completely satisfactory explanation of the rise and subsequent fall in cell sensitivity as sensitization proceeds. It is analogous to the variation in cell sensitivity found during the manufacture of normal lead sulphide cells as the layer moves from an excess to a deficit semiconductor[2]; but it is curious that the point of maximum sensitivity does not coincide with a point of maximum dark resistance. The time constant of the cell (defined as the time taken for a signal to decay to $1/e$ of its original value) also passes through a maximum at about the same time as maximum sensitivity is reached.

The spectral response of the cells moves to longer wave-lengths during sensitization, the spectral limit reaching about the value found for normal lead sulphide cells at 90° K. when maximum sensitivity is reached[5].

The above work was carried out in the laboratories of the Telecommunications Research Establishment, Great Malvern, and thanks are due to the Chief Scientist, Ministry of Supply, for permission to publish this note.

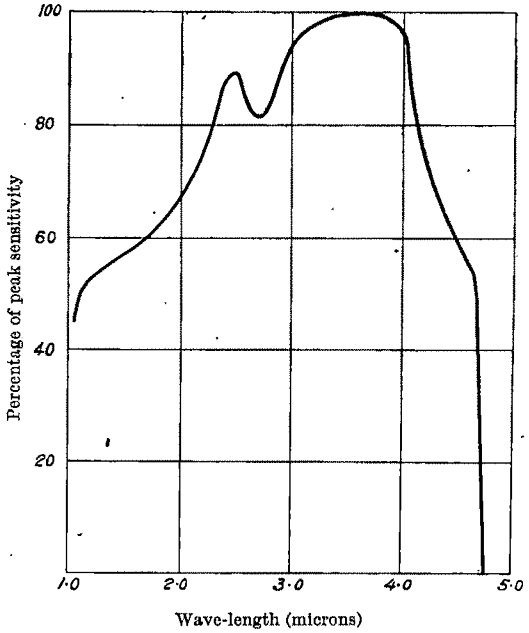
Lead Selenide Photoconductive Cells

The superiority of lead selenide photoconductive cells over lead sulphide cells and over purely thermal infra-red detectors in the 3–4 μ region has already been described[1,2]. The preparation of these sensitive layers has always been by an evaporation method[3,4] analogous to that previously used for lead sulphide[5]. Chemical deposition processes[6,7] for the preparation of lead sulphide cells have been further developed by us, until comparable sensitivity at room temperature and greater sensitivity at low temperatures than those obtained with evaporated cells are available.

We have recently made successful trials of a chemical process for preparing lead selenide layers, based on information about a process tried with unknown results by Sommer in Germany[8]. A thin film of lead sulphide is first deposited on the cell blank to act as a seed layer for the growth of the lead selenide microcrystals. This film is prepared by a short immersion in a bath of lead acetate and thiourea, while this is gradually made strongly alkaline. The lead selenide is then deposited on this seed layer from a bath of lead acetate and selenourea; this reaction is much slower than the lead sulphide deposition and usually requires about an hour to develop a sufficiently thick layer of lead selenide. The lead selenide film is then subjected to a partial oxidation by baking in air to about 300° C. for 10–15 min.



The sensitivity of these lead selenide cells when cooled with liquid air is such that a signal equal to noise is obtained for 10^{-8} to 5×10^{-9} watt/mm.² of 200° C. black-body radiation, 800 c./s. interruption frequency with 30 c./s. band-width. A typical spectral distribution curve at liquid air temperature is shown in the accompanying graph. It will be observed that this type of lead selenide cell has a broad maximum at 3–4 μ, in this respect resembling the cells reported by Starkiewicz[4]. The position of the long-wave cut-off could not be exactly determined owing to the use of fused silica windows, which absorb strongly in the 4·5–5 μ region; good sensitivity, however, exists up to at least 4·6 μ.

These cells have so far only exhibited appreciable sensitivity at low temperatures, such as those of solid carbon dioxide and liquid air. The investigation is, however, still in an early stage, and these preliminary results are encouraging.

Plastic Deformation of Optical Glass

I DESCRIBED recently a form of hardness micro-tester which permits light loads to be applied to a diamond indenter of pyramidal form as a means of determining the hardness figures of minute individual crystals in a mosaic[1]. It is also possible with the same instrument to draw the loaded indenter across a surface and to determine the hardness figure by means of a scratch test.

It was intended by this latter means to attempt to assess the hardness figures of many of the known types of optical glass, and a beginning was made in this direction. In addition, the opportunity presented itself of observing the form of the resulting fracture when the loaded indenter was used in a static manner and brought into contact with a plane polished glass surface. It was then discovered that a lightly loaded pyramid diamond left a perfectly defined and lasting impression on the polished surface. Thus, in the case of borosilicate crown and extra dense flint glasses, perfect impressions were formed with loadings up to about 50 gm.; with loadings of 100 gm., fractures appeared emanating generally from the corners of the square impression, and at some intermediate loadings fractures sometimes appeared after a short interval of time (Fig. 1).

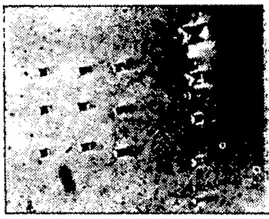

Fig. 1

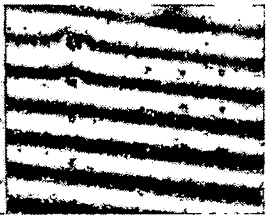

Fig. 2

Fig. 1. Nine impressions under load of 20 gm. Single impressions under loads of 100, 50, 20, 10 and 5 gm. × 200

Fig. 2. As Fig. 1, but with the addition of interference fringes which indicate a raised rim around the two larger impressions. (Wave-length, 546 mμ.) × 200

With borosilicate crown glass 509/650, the diagonals of the impression under a load of 50 gm. measured about $12{\cdot}3\,\mu$, giving a hardness figure of 613; and under identical conditions the hardness figure for extra dense flint glass 650/337 was 433 with the diagonals measuring $14{\cdot}6\,\mu$.

The interesting fact is that the surface layer was found to be sufficiently plastic to take an impression. Thus, with a loading of 100 gm. the volume of the displaced borosilicate crown glass was $115\,\mu^3$, and an interference test showed a raised rim of glass around the depression (Fig. 2). The volume of glass raised above the original surface was found to be about $90\,\mu^3$, but accurate measurement was difficult and there may well be perfect correspondence.

In view of the uncertainty which exists regarding the nature of a worked glass surface[2,3], similar tests were carried out on a newly fractured and on a fire-polished surface of the same borosilicate crown glass. No difference in behaviour was noted and no evidence was forthcoming to support the presence of a soft superficial layer of glass on the optically worked specimen.

A Theoretical Comparison of the Performance of Stationary-Target Crystallographic X-Ray Tubes Operating on Alternating and Direct Voltages

IT has been suggested that if a normally self-rectifying crystallographic X-ray tube is operated on D.C. instead of A.C., it should be possible approximately to double the power input to a tube and therefore similarly to increase the X-ray output. Unfortunately, this does not take into account the fact that the maximum target loading, determined by consideration of the heat dissipation, is normally obtained in a tube using A.C., so that at first sight it would seem to be impossible to increase the power input by operating the tube on D.C. However, as Terrill and Ulrey[1] point out, the temperature of the focal spot will fluctuate with each half-cycle in the case of A.C.; if the maximum temperature obtained is equal to the maximum permissible temperature for the target, which is also the steady temperature in the D.C. case, it follows that the average temperature will be lower for A.C. than for D.C. Thus the power input with A.C. must be made smaller than with D.C. in order that the maximum temperature shall not exceed the safe value. Terrill and Ulrey give no actual figures for this difference, but DeGraaf and Oosterkamp[2] state that with a four-valve circuit the maximum load is roughly 15 per cent higher than for A.C., and that for a well-smoothed 'Greinacher' voltage it is about 20 per cent higher.

It can be shown theoretically, moreover, that for a *given* power input the mean intensity of characteristic radiation is slightly greater for a D.C. high-voltage supply than for A.C., and so also, under certain conditions, is the ratio of intensities of characteristic and white radiations.

The relation[3] between the intensity I of the characteristic radiation, the current i passed by the tube, and the voltage V applied to it, is given by:

$$I = Ai\,(V - V_k)^{1\cdot5},$$

where V_k is the critical voltage for the material of the anode, and A is a constant.

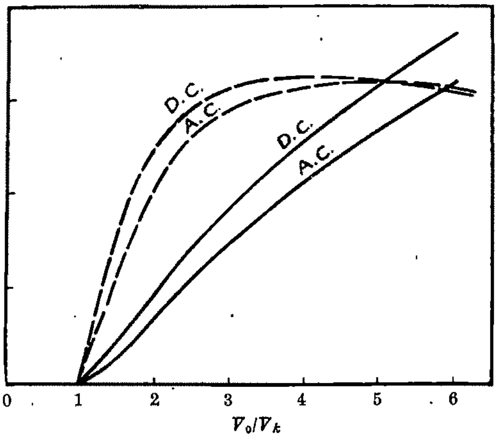
In the case of D.C., values of voltage and current can be substituted directly in this equation; but for the A.C. case it is necessary to obtain the mean value of this function over the whole voltage cycle, and this involves the integration:

$$I = A\,\frac{1}{\tau}\int_0^{\tau} i(V - V_k)^{1\cdot5}\,dt,$$

where τ is the periodic time of the A.C. supply, and V is the instantaneous voltage at any point in the cycle. This integration has been carried out numerically, including only that part of the cycle where $V > V_k$.

The accompanying figure shows the variation of the intensity I with voltage V_0 for both A.C. and D.C., the mean target loading, that is, the power input, being the same in both cases. In the A.C. case, V_0 represents peak voltage, and it has been assumed that the voltage wave-form is purely sinusoidal; in the D.C. case, V_0 has the same value as V.

The curves have only been drawn to values of $V_0/V_k = 6$, as at higher voltages it has been shown



Full lines, variation of intensity; broken lines, variation of contrast

practically that the intensity approaches asymptotically a limiting value[4].

Another important factor in crystallography is the ratio of the intensities of the characteristic and white radiations, which we might designate as contrast. The white radiation intensity[5] is proportional to iV^2, and hence for the D.C. case, a measure of contrast (C) is given by:

$$C = A(V - V_k)^{1\cdot 5}/A'V^2.$$

In the case of A.C., integration is again necessary, the relation being:

$$C = A \int_0^T i(V - V_k)^{1\cdot 5}\,dt/A' \int_0^T iV^2\,dt.$$

The variation of contrast with voltage for the two cases is also shown in the figure. It will be seen that the contrast curves each show a definite maximum, occurring when V_0 is equal to $4V_k$ for D.C. and $5V_k$ for A.C., the former being about $1\frac{1}{2}$ per cent higher than the latter. Thus if the high-tension voltage is increased above these values, although there may be a slight increase in intensity there is a slight decrease in contrast. This explains the use of a voltage of about $5V_k$ to obtain the best results with the typical crystallographic X-ray set, the desired intensity being obtained by varying the emission current. This has no effect on the contrast, since both line and background intensities are affected to the same degree by altering the current.

The intensity curves show that, for a constant power input, and working at the usual voltage of $5V_k$, the theoretical increase in intensity obtained by using D.C. is about 18 per cent. This, combined with the possibility of a 20 per cent increase in the power input using D.C., results in a total increase in intensity of approximately 40 per cent.

It is therefore concluded that the increase in intensity obtained by operating a stationary target X-ray tube on a D.C. high-tension supply as opposed to an A.C. supply, although advantageous in itself, is considerably outweighed by the additional expense and maintenance of a D.C. supply. The ratio of characteristic radiation to white radiation, referred to here as contrast, is practically unchanged.

Metallic Delay Lenses

AN experimental study of the metallic delay lens described by Kock[1] has been made in this Establishment, using a lens constructed of parallel strips as in Fig. 1, the E vector being normal to the line of the strips. The dimensions were such that Kock's formula for refractive index

$$n = \sqrt{1 + \frac{\pi}{4} s^2 N},$$

where s is width of strips and N is number of strips per unit area viewed end on, gave the value 1·41 for n. The predicted cut-off wave-length was 1·8 cm.

An experimental investigation of the optics of the lens gave a refractive index of 1·71 at $\lambda = 10\cdot 0$ cm. The same degree of accuracy could not be achieved with $\lambda = 6\cdot 0$ cm., but there was no measurable difference in the value of n. For $\lambda = 3\cdot 0$ cm. the lens was practically opaque.

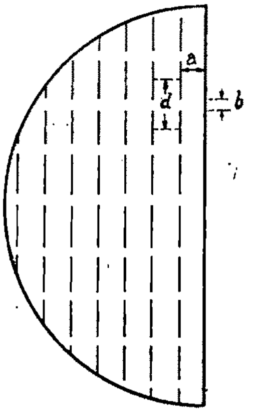

Fig. 1. Metallic delay lens

A new formula for refractive index has been calculated on the assumption that the refracting medium behaves similarly to a transmission line the characteristic impedance of which is that of air loaded at equal intervals by a capacitance, which depends on the width of the metal strips and the gap between them. The method of calculation is similar to those employed by Macfarlane and others in the study of wave-guides[2]. The computed values of refractive index are shown in Fig. 2, the cut-off wave-length being $\lambda = 2\cdot 97$ cm.

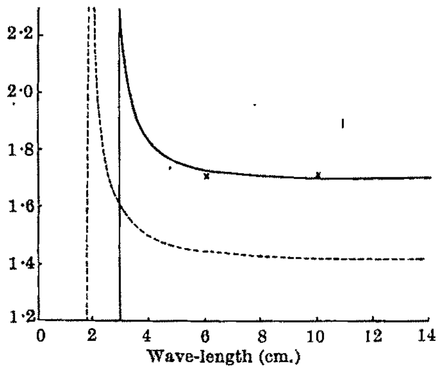

Fig. 2. Refractive index of metallic delay lens. ×—×—, observed points; full line, new formula; broken line, Kock's formula. Two vertical lines, broken and full, show cut-off at $\lambda = 1{\cdot}8$ and 2·97 cm., respectively

Over the range of wave-lengths for which the refractive index is constant, its value is given by:

$$n^2 = 1 + \frac{2d}{\pi a}\log_e\left(\operatorname{cosec}\frac{\pi b}{2d}\right),$$

where the distances a, b, d are as shown in Fig. 1.

The new formula predicts a value of n which is observed within experimental accuracy, whereas the formula given by Kock gave a value 18 per cent too low.

It is hoped to publish a fuller account of this work elsewhere.

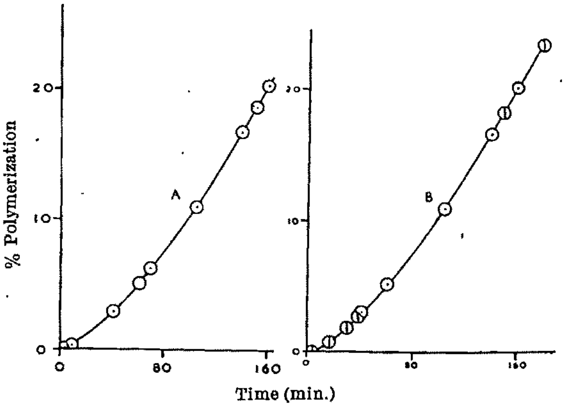
A New Catalytic Effect in Vinyl Polymerizations

In his experiments on the polymerization of vinyl chloride catalysed by benzoyl peroxide, Prat[1] observed that the rate of polymerization increased throughout the first 40 per cent of reaction. This acceleration he suggested might be either due to the gradual attainment of a steady state, consequent upon the existence of long-lived radicals, as suggested by Dostal and Mark[2], or alternatively to consecutive initiation reactions, as put forward by Cuthbertson, Gee and Rideal[3] to interpret a similar phenomenon in the case of vinyl acetate. This phenomenon in the case of vinyl acetate was later shown[4] to have been caused by the presence of impurities in the monomer.

Now the polymer which separates from liquid monomeric vinyl chloride is insoluble in the monomer. It is, therefore, possible to use a sealed dilatometer to give an accurate measure of the rate of polymerization. Such dilatometers containing accurately measured quantities of the benzoyl peroxide catalyst were filled with highly purified monomer by distillation in a high-vacuum apparatus, and sealed off. The results of Prat were confirmed: if the monomer had been insufficiently purified there was an induction period of up to several hours depending on the amount of catalyst added, during which absolutely no reaction could be observed, followed by a period of acceleration lasting for the first 40 per cent of reaction. Repeated purification (in particular from acetylene) reduced and finally removed completely the period of induction, but had no effect on the period of acceleration or the rate of the reaction.

In order to prove that this acceleration of the reaction in the case of vinyl chloride is a true kinetic effect and independent of impurities which are removed as the reaction proceeds, the following experiment was devised. Some purified vinyl chloride was polymerized to an extent of about 20 per cent conversion, in the presence of 1·04 mol. per cent benzoyl peroxide at 47° C.; the unchanged monomer was then distilled under vacuum into a second dilatometer which contained an amount of benzoyl peroxide such that its concentration in the new solution was equal to that in the original; the polymerization in the second dilatometer was then followed at 47° C.



Polymerization of vinyl chloride, catalysed by 1·04 mol. per cent benzoyl peroxide at 47° C. ⊘, original monomer; ⦶, unchanged monomer

In the accompanying graph, curve *A* represents the course of the first polymerization, and curve *B* that of the unchanged monomer. It is seen, on plotting the results from curve *A* on curve *B*, that both polymerizations proceed in an identical manner. It was then found that if vinyl chloride is polymerized to about 20 per cent polymerization, the unchanged monomer removed, and an equal quantity of fresh monomer added, the continued polymerization proceeds at the accelerated rate. This evidence makes clear that the phenomenon of acceleration is not caused by impurities which retard the rate initially, and indicates the conclusion that the polymerization is in some way catalysed by the precipitated polymer.

In confirmation of this, we have found that when polyvinyl chloride is added to vinyl chloride containing 0·5 mol. per cent benzoyl peroxide, and the mixture polymerized at 47° C., the rate of polymerization increases with the amount of polymer added; but in the absence of benzoyl peroxide no polymerization is observed even when large amounts of polyvinyl chloride are added. Further, if a solvent for the polymer, such as dibutylphthalate or tetrahydrofuran, is added to vinyl chloride catalysed by benzoyl peroxide at 47° C., the polymerization proceeds in the homogeneous phase at a constant rate throughout the early stages of the reaction, without any indication of the acceleration observed when the polymer is precipitated.

The conditions for polyvinyl chloride to exert a catalytic effect are therefore: (*a*) that it is present in an undissolved state; and (*b*) that benzoyl peroxide, or some other source of reactive free radicals, is also present in the system. It is suggested that this co-catalytic effect is due to a gradual increase in the total number of active centres as the polymer accumulates in the system. The additional centres are believed to be derived by a chain transfer reaction between free radicals and conglomerates of polymer, thus producing immobile radicals in the surface of the polymer which are largely free from the process of self-neutralization which occurs in the liquid phase. The number of these radicals will be proportional to the surface area of the polymer and also to the number of mobile radicals present, while the latter will depend upon the concentration of the catalyst. As the reaction proceeds there will therefore be an increase in the number of radicals present and consequently an increase in reaction-rate.

It is well known that 'polymer begets polymer'. For example, with vinyl chloride it has been found in technical operation that if a small amount of polymer be formed at a bend or constriction of a pipe conveying the liquid monomer under pressure, this will grow in course of time, often with serious results. Upon the above ideas it is easy to see that, even in the absence of catalyst, adventitious centres in the monomer can react, by transfer with the polymer as they flow past, to produce an active surface, which will cause the initial seed to grow continuously though slowly until the pipe is blocked.

A detailed kinetic analysis has been made, and this, together with full experimental results, will appear elsewhere.

Photo-chemical Activity of Paint Pigments

Recent experience has shown that certain grades of zinc oxide of local manufacture markedly accelerated the initiation of chalking in paint films. In the course of an investigation into these differences, it was observed that they corresponded to differences in the fluorescent behaviour of the zinc oxides when irradiated with ultra-violet light. The zinc oxides (Series *A*, three samples from two manufacturers), prepared by burning zinc vapour in air (French process), showed no visible fluorescence at room temperature and markedly accelerated the initiation of chalking, as compared to the zinc oxides (Series *B*, four grades from three manufacturers) prepared by burning zinc vapour in air containing reducing gases (as in the American process), which showed a strong yellow fluorescence.

This result is in apparent conflict with some statements made in the literature[1], but a comparative test for fluorescence using an 'Osira' lamp has provided a useful means of selecting non-chalking grades of zinc oxide available in Australia.

A distinct difference in the photo-chemical activities of (*A*) and (*B*) was also noted. An aqueous suspension of (*A*), after irradiation for a short period with an 'Osira' lamp, was found to contain hydrogen peroxide[2], liberating iodine from potassium iodide solution, decolorizing permanganate solution and giving a yellow colour with titanium sulphate solution. Longer irradiation by direct sunlight also caused formation of hydrogen peroxide. A suspension of (*B*) treated in the same way gave no reaction for peroxide.

The major contributing factor in the different performances of paints containing (*A*) and paints containing (*B*) must be that in the former the high-energy portion of the solar radiation is utilized as photo-chemical energy, whereas in the latter it is dissipated as lower-energy radiation[3]. From (*A*) the energy may be transferred directly to the unsaturated fatty oil, providing the energy required for the removal of hydrogen from the α-methylenic group, this being the initial step of the oxidation suggested by Farmer[4]. From the above evidence, however, it appears to be more likely that transfer of energy to oxygen takes place followed by entrance of molecular oxygen at the double bond, as suggested by Hilditch[5]. The production of hydrogen peroxide in the presence of water also provides an explanation for the observed acceleration of chalking under moist conditions.

It is hoped that a detailed study of the fluorescence spectra and their dependence on environment for a number of differently prepared zinc oxides and other pigments will provide further information about their influence on the photo-chemical oxidation of paint vehicles.

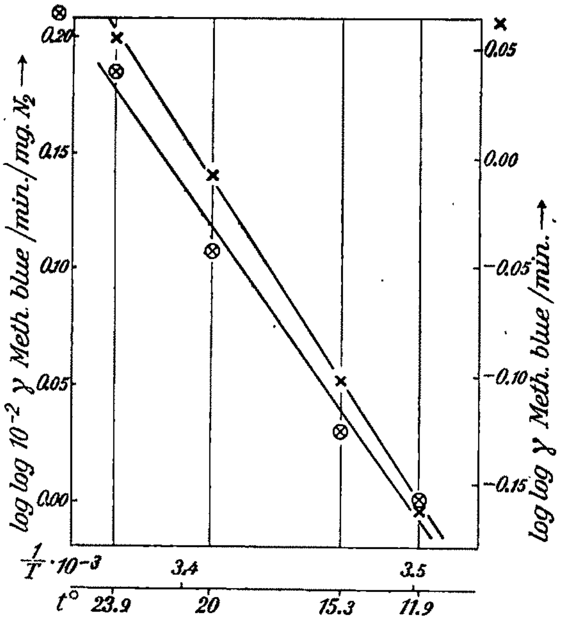
Thermal Activation of the Dehydrogenase Systems of the Unfertilized and Fertilized Eggs of the Sea Urchin, *Paracentrotus lividus*

Runnström[1] and Örström[2] were the first to try to compare the dehydrogenase activity in the sea urchin egg (*Paracentrotus lividus*) before and after fertilization by means of methylene blue reduction experiments. They could not reveal any difference. However, Ballantine[3], carrying out similar experiments, was able to demonstrate a rise in the rate of methylene blue reduction in the sea urchin *Arbacia punctulata* ranging from 2·2 to 3·7 times. In 1939 Miss Inger Stordal, in preliminary experiments in collaboration with one of us (P. E. L.), proved the methylene blue reduction by fertilized eggs to have a higher temperature coefficient than that of the unfertilized egg. The completion of these experiments was postponed because of the outbreak of war.

Our experiments carried out at Roscoff (France), at a temperature of about 12°, 16°, 20° and 24° C., confirm this result; thus the difference in reduction-rate is nil, or comparatively small, at 12°, but rather considerable at 24° C. This is due to the different slopes of the temperature curves, and also to the different forms of the curves, those of the fertilized eggs being more bent than those of the unfertilized ones. Further analyses of these data reveal that, for the unfertilized eggs, the logarithm of the reduction-rate plotted against $1/T$ forms a straight line; but for fertilized eggs there is still a bent curve. If, however, the logarithm of the reduction-rate of the fertilized eggs once iterated is plotted against $1/T$, an approximately straight line is obtained (see graph). Thus the thermal activation seems to follow the Arrhenius equation in the unfertilized egg, whereas a more complicated relationship holds for the fertilized egg.



The rate of methylene blue reduction is referred to 1 mgm. of egg nitrogen (except in the experiments with egg extract). ⊕, fertilized eggs; ×, egg extract + coenzyme I + glucose-6-phosphate

It is well known from Warburg[4], Runnström[5] and others that the respiration of unfertilized sea urchin eggs slowly rises, this process being suppressed by agents inhibiting the respiration[5]. As in the experiments described, the unfertilized eggs were handled for about two hours before the performance of the measurement; during washing and mechanical removal of the jelly coats, their respiratory state was supposed not to correspond to the original one typical of the egg as expelled from the ovaries. Thus the ovaries were allowed to discharge into sea-water of 10° C., at which temperature the eggs were kept during the preparations. In such cooled unfertilized eggs the thermal activation is of still another type, the rate of methylene blue reduction giving a straight line when plotted against $1/T$.

We have thus observed three different types of thermal activation of the dehydrogenase activity in eggs: (1) that of the cooled, unfertilized eggs, representing the state of those freshly laid; (2) that of the uncooled eggs, representing the state after some hours in sea water; (3) that of the fertilized egg.

The difference in thermal activation of the fertilized and the unfertilized (cooled) eggs disappears when the eggs are crushed by adding distilled water, the same type of curve being obtained as in the case of cooled unfertilized eggs. We are unable to suggest any theoretical explanation for this type of curve. When, however, coenzyme I and glucose-6-phosphate are added to an almost clear egg extract, obtained by centrifuging crushed eggs, the very high rate of methylene blue reduction resulting shows a thermal activation identical with that of the fertilized living egg (see graph).

The dependence of the rate of the methylene blue reduction in an exponential way on the rate of another reaction, for example, a phosphorylation—the thermal activation of which follows the Arrhenius equation—may possibly be the basis of this iterated logarithmic function. Such a coupling between oxido-reduction processes and phosphorylations is well known to exist, for example, during the exponential induction phase of artificial fermenting systems. According to Lindberg and Ernster[6], the oxidation of glucose in homogenized sea urchin eggs is coupled with the esterification of phosphate.

Effect of Necrosin on Spontaneous Tumours in Swiss Mice

I HAVE demonstrated within the last decade the presence, in inflammatory exudates, of various substances with definite biochemical properties. These substances are at present relatively crude, and it is hoped they will be purified further. Analysis of the exudate reveals some substances, which appear to be polypeptide in some cases and proteins in others, capable of reproducing the same effect as the whole exudate. Blood serum fails to show the presence of these substances unless there is a concomitant inflammation. This would indicate that presumably these substances penetrate from the site of injury into the circulation, for in the early stage of an inflammation they are absent from the blood, whereas they can already be detected at the site of an acute inflammation[1].

One of these substances is concerned with the basic pattern of injury in inflammation. It is closely associated with the euglobulin fraction, particularly of acid exudates. I have given the term 'necrosin'[2] to this substance. Its introduction into normal tissue induces severe injury with all the signs of an acute inflammation. Other protein fractions of exudative material fail to produce a similar picture.

Necrosin is found in the euglobulin fraction of exudates, freed in turn of insoluble material in the presence of electrolytes. Ludford[3] and Duran-Reynals[4] have shown that dyes or proteins are localized into tumours. Duran-Reynals ascribes this localization to the greater permeability of capillary vessels in a tumour than is found in normal circumstances[4]. For this reason necrosin, as a substance associated with a protein fraction of exudates, was injected into about two hundred Swiss mice with spontaneous tumours. The tumour is a mammary one and it is very vascular. The subcutaneous injections of the material were always made at a distance from the tumour. The amount of necrosin administered in the fluid state varied from an equivalent dose of 0·2 μgm. of necrosin to 1,748 μgm. of lyophilized necrosin. After one or several injections, the material induced hæmorrhagic or other forms of necrosis, such as a mucoid-like yellowish fluid, or rarely a caseous-like central necrosis, in the tumour. Hæmorrhagic necrosis was also found to occur in some of the metastatic foci of the lung. A certain amount of necrosis in these areas appeared as early as one hour after the administration of necrosin. This toxic substance concomitantly causes hepatic injury in the form of vacuolation of the cytoplasm of the liver cells. Sometimes one encounters various forms of leucocytic infiltration in the liver. Whether or not the hepatic injury is the cause of the death of the animal is not yet clear. At times, injury to the kidney is also seen in the form of foci of leucocytes. This and other factors are at present under investigation, for to date there is no evidence that the span of life is prolonged with necrosin treatment. Nevertheless, the effect is specific and does not occur with other protein fractions, such as the euglobulin of normal blood serum or with papain. Further work is being conducted with different strains of mice; methods are also being devised to counteract the toxic effect of necrosin on the liver.

Para-Aminobenzoic Acid in Human Leukaemias

BICHEL[1], and later Zarafonetis and co-workers[2], recorded interesting data concerning the effect of *para*-aminobenzoic acid in leukæmias.

In an attempt to confirm Bichel's findings, we investigated the effect of a single intravenous injection of *p*-aminobenzoic acid on patients with leukæmias, and on controls; we administered the sodium salt in 3–5 per cent solution. The intravenous infusions were given for 10–21 minutes. In each case the total amount was 5 gm. The *p*-aminobenzoic acid serum levels (maximum) ranged from 18 to 31 mgm. per cent.

We made nine trials in seven patients with leukæmias and six trials in six persons not suffering from this group of diseases. The patients tested could be grouped as follows according to clinical condition: three chronic myelocytic leukæmic myeloses, one subchronic promyelocytic–myelocytic leukæmic myelosis, one chronic subleukæmic lymphoid leukosis, one chronic aleukæmic lymphoid leukosis, and one acute paraleukoblastic form. The group free from leukæmia included one healthy individual, one with Hodgkin's disease, one with Vaquez–Osler disease, one with cirrhosis hepatis, one with Besnier–Boeck–Schaumann disease, and one case of rheumatic fever.

We found that all four patients with myelocytic leukæmia developed a fever response, with chill and shivering, which occurred between one and four hours after the injection had been given. The fever might exceed 39° C. (102° F.), and showed no close relationship to the *p*-aminobenzoic acid blood-level or to the speed of the infusion. The two patients with lymphoid leukæmias and the case of acute paraleukoblastic form did not show this reaction; nor did the non-leukæmic controls.

The total and differential leucocyte counts, and the cells of the spleen (the latter were examined in only two cases), did not show constant significant deviations. It was remarkable that in our leukæmic patients the renal elimination of *p*-aminobenzoic acid occurred in the same manner as we have described for healthy individuals.

Our evidence to date indicates that the phenomenon here noted cannot be obtained if the leucocyte-producing system is under the influence of a completely developed urethane effect[3].

We suggest a humoral basis for the shivering and fever, and conclude that it may be caused by some substance liberated from the leukæmic leucocytes as a result of the administration of *p*-aminobenzoic acid. To confirm this view, experiments are in progress with whole blood, with serum, and with leucocytes, etc., inoculated into guinea pigs.

We hope to publish the results of these tests, and also of the investigation reported above, in detail later elsewhere.

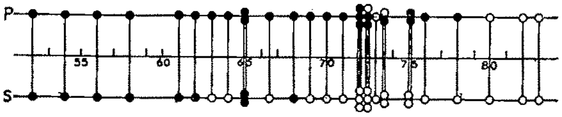
Failure of Transmission of Motor and Sensory Nerve Impulses after Nerve Section

HITHERTO the time at which failure of transmission of nerve impulses occurs following section of the nerve trunk has been determined in mixed nerves only. In the popliteal and sciatic nerve of the cat it was found to occur after about three and four days respectively[1,2]. Erlanger and Schoepfle[3] found degeneration in the phrenic nerve to be complete after about four days.

It is possible that failure of impulse transmission after nerve section sets in at different times in different groups of nerve fibres. Indeed, Moenkeberg and Bethe[4] had shown histologically that degeneration proceeds more quickly in sensory than in motor nerve fibres, and von Muralt[5] as well as Rosenblueth and Dempsey[6] consider that the thick nerve fibres with a rapid conduction-rate degenerate earlier than the thin, slowly conducting ones. Rosenblueth and Dempsey found that in a few nerves the *A* spike had already considerably decreased at a time at which the *C* spike was still normal. They supported their conclusion also by the fact that the rate of conduction increased in the degenerating nerves when the stimulating electrode was moved peripherally towards the recording electrode, suggesting that degeneration followed a centrifugal course. However, Erlanger and Schoepfle showed that failure of nerve conduction does not proceed centrifugally, but that conduction fails at scattered loci increasing in frequency peripherally.

We have re-investigated the question by using for comparison the sural and peroneal nerve of the rabbit. The sural nerve, apart from its sympathetic contribution, is a purely sensory nerve; the peroneal nerve, apart from its sympathetic contribution, contains afferent and efferent fibres from and to skeletal muscles. The nerves were excised at different times after section and placed in a thermostat on platinum electrodes. The temperature of the chamber varied from 36° to 38° C., but was approximately constant for any given set of observations. The electrical responses of the nerves were recorded by a cathode ray oscillograph (highest sensitivity 80 microvolts/cm.), the distance between stimulating and recording electrodes being 2–4 cm.

The time at which the nerves failed to conduct impulses after nerve section varied considerably in different animals, and was to some extent dependent on the age of the animal. Therefore the comparison was always made for the nerves of the same animal, and one- to two-year-old rabbits were used. From the accompanying diagram it will be seen that in the same animal impulse conduction failed about 10 hr. earlier in the sural than in the peroneal nerve. In the sural nerve, it failed after about 63–68 hr.; in the peroneal, after about 72–80 hr.



Times in hours at which the excitability of the peroneal (P) and the sural (S) nerves were tested following nerve section. Both nerves are taken from the same animal. Filled circles: action potential could be recorded; empty circles: no action potentials could be recorded when stimulating the nerve

Further evidence in favour of differences in the time course of degeneration in different groups of nerve fibres was provided by the electrical responses of the degenerating nerves. The height of the spike potential decreased with increasing time of degeneration. Moreover, in the sural nerve two spikes could be observed at the beginning, but one only at later stages of degeneration. The nerve fibres thus appear to cease functioning successively and according to a certain order.

We may conclude that the sensory fibres from the skin degenerate earlier than the afferent and efferent fibres in motor nerves. The thickness of the myelin sheath may be the main factor in determining the time course of degeneration after nerve section. These findings may be useful when classifying nerve fibres according to their morphological and physiological characteristics.

Determination of Proteins in Cerebro-Spinal Fluid

It appears from conversations I have had with medical officers concerned with trypanosomiasis that there is a need for a reliable and rapid method of estimating the protein content of cerebro-spinal fluid. Existing methods that rely either on the estimation of opalescence or volume of precipitate[1,2], when a protein-precipitant is added to cerebro-spinal fluid, are open to a number of obvious objections.

I have found that the xanthoproteic reaction can be made quantitative and that an easily reproducible artificial standard can be used. The method is as follows:

Reagents. $M/3$ zinc sulphate solution; $N/2$ sodium hydroxide solution; 6 N nitric acid solution; 10 N sodium hydroxide solution. *Procedure.* Dilute 2·0 ml. of cerebro-spinal fluid with 4 ml. water in a centrifuge tube. Add 0·1 ml. $M/3$ zinc sulphate; mix. Add 0·1 ml. $N/2$ sodium hydroxide; mix and centrifuge. Decant the supernatant liquid and drain well. Add 3 ml. 6 N nitric acid and place the tube in boiling water for 15 min.; cool. Add 2 ml. 10 N sodium hydroxide. Cool and dilute to 6·0 ml. Compare the colour of the solution so produced with a suitable dilution of an accurately standardized solution of potassium dichromate.

The protein content of the cerebro-spinal fluid is given by: mgm. per cent of protein $= T/S \times C \times 1{\cdot}6$, when T/S is the ratio of colour intensity produced by the above method to that of the standard; C is concentration of standard dichromate solution in mgm. per cent of $K_2Cr_2O_7$.

The zinc hydroxide precipitate packs down well, even in a small hand-operated centrifuge, so that the method can be used in field stations. Alternatively, the zinc precipitate may be collected on a sintered-glass filter and afterwards washed through into a fresh tube with 3 ml. of hot 6 N nitric acid divided into small portions. 'Globulin' may be determined by adding to cerebro-spinal fluid an equal volume of saturated ammonium sulphate solution (adjusted to pH 5·4 with acetic acid) and separating the precipitate. The test may then be applied to this precipitate, giving 'globulin'. 'Albumin' can be calculated by difference from total protein.

The zinc hydroxide precipitation is only necessary when there is a possibility of the presence in the cerebro-spinal fluid of compounds, other than proteins, containing aromatic nuclei, for example, tryparsamide, sulphanilamide or similar drugs. If such compounds are known to be absent, the test may be applied directly by adding 1 ml. of concentrated nitric acid (s.g. 1·42) to 2·0 ml. of cerebro-spinal fluid and proceeding at once with the 15-min. heating in boiling water. The subsequent steps are the same as already described.

The dichromate solution is not of exactly the same colour shade as that produced in the test but is close enough to it to be almost indistinguishable in a Du Boscq or 'wedge' type of colorimeter when the protein in the cerebro-spinal fluid is less than 40 mgm. per cent, which is the most important range. A phenol solution may be used as a colour standard and gives a closer approximation to the shade of the test colour when put through the same process; but it was considered that for field use a hollow wedge colorimeter with dichromate solution in the wedge was the easier with which to work. It was interesting to note that when a Spekker photo-electric absorptiometer was used with Chance 0B1 filters, the protein values obtained with the dichromate standard were only slightly greater (less than 5 per cent) than those determined visually in a colorimeter, using the same standard.

A micro-Kjeldahl method, adapted from a combination of the methods of King, Haslewood and Delory[3,4], and of Miller and Miller[5], was applied to individual samples of cerebro-spinal fluid and also to bulked samples. The figures for protein concentrations thus obtained were used to calibrate the dichromate standard. Unfortunately, owing to pressure of other work, it was not possible to devote as much time to this work as was desirable. The factor (1·6) relating dichromate colour to xanthoproteic colour cannot, therefore, be assumed to be absolutely accurate, but is not likely to be far wrong. In only a small proportion of the samples did the factor differ greatly from 1·6. This seems to justify the assumption that, although the colour developed in the test is dependent on the presence of phenyl groups in the protein, the proportion of these is substantially constant in the proteins of the cerebro-spinal fluids tested.

The factor 6·25 was used to convert the Kjeldahl nitrogen figures into protein figures. This assumption can only be checked by isolating and purifying the protein from cerebro-spinal fluid.

It is hoped to check and undertake a more detailed study of the method when an opportunity arises. However, as I can find no previous reference to a similar method, it appears desirable that these preliminary findings be made known so that other workers might be able to examine the method.

I wish to express my thanks to Dr. G. F. Saunders for indispensable help in obtaining samples of cerebro-spinal fluid and for his interest and constructive criticism, to Dr. G. Tooth for first bringing to my notice the need for a simple method of estimating proteins, and to Dr. J. G. S. Turner, director of Medical Services, Gold Coast, for permission to submit this note for publication.

2 : 3 Dimercaptopropanol (B.A.L.) and Methyl Iodide Intoxication

LEWIS[1] has reported the inhibition of SH enzymes by methyl bromide. It is therefore of interest to note that we have found a similar effect with methyl iodide.

Kerateine was prepared from sheep's wool by the method of Goddard and Michaelis[2]. A 0·2 per cent solution of kerateine in 0·1 *M* sodium carbonate was exposed to an atmosphere containing 10 mgm. of methyl iodide per litre, and a progressive decrease in the colour given with sodium nitroprusside was noted.

A suspension (0·5 per cent) of urease was made up (1) in distilled water, (2) in 0·98 *N* methyl iodide, and (3) in 0·98 *N* methyl alcohol/potassium iodide mixture. After standing four hours, 15 ml. of the urea/phosphate mixture of Sumner[3] was added to each. The mixtures were allowed to stand at room temperature, 21° C., and at intervals samples were withdrawn and ammonia determined with Nessler's reagent. An inhibition of about 50 per cent was found with the methyl iodide mixture, whereas the methyl alcohol/potassium iodide mixture was as active as the control, showing that the inhibition is due to the methyl iodide molecule as a whole.

Inhibition of urease by methyl iodide

Mixture	Ammonia (mgm./ml. reaction mixture)		
	At 20 min.	At 40 min.	At 60 min.
1	2·1	3·75	5·8
2	1·25	1·75	2·25
3	1·9	3·2	6·0

These results led us to try the effect of B.A.L. in methyl iodide poisoning in mice. A dose of 50 mgm. B.A.L. per kilo body-weight administered before exposure gives complete protection from a concentration which would otherwise be lethal for all the animals in a group; but B.A.L. given immediately after exposure has only slightly prolonged the time of survival.

Estimation of Digestibility of Grazed Pasture from Fæces Nitrogen

IN a recent communication in *Nature*, Raymond[1] has proposed a method of estimating the nitrogen content and the related nutritive value of pasture herbage consumed by grazing sheep from the nitrogen content of the resulting fæces. While this relationship should prove very useful in sheep nutrition studies, it appears likely, on the basis of work carried out at this Station[2,3], that a still more precise expression of the nutritive value of the herbage can be obtained from the data used by Raymond. It is the purpose of this communication to describe how the organic matter digestibility of pasture can be calculated from the nitrogen content of the fæces.

As a result of an analysis of the data from digestibility trials carried out at widely dispersed centres in New Zealand, a hypothesis was set up to the effect that the nitrogen excreted in sheep fæces per unit intake of pasture organic matter is constant. Knowing the value of this constant (C), and the concentration of nitrogen in the ash-free fæces (n per cent), the amount of organic matter in the herbage giving rise to 100 gm. of fæces organic matter will then be $100n/C$ and the digestibility will be given by

$$D = \left[\frac{\frac{100n}{C} - 100}{\frac{100n}{C}}\right] \times 100 = 100\left[1 - \frac{C}{n}\right]. \qquad (1)$$

The value of C calculated from the data under analysis was 0·83 ± 0·102 gm. nitrogen per 100 gm. of pasture organic matter consumed. These data were collected from fifty-two digestibility trials[3] covering pastures ranging in organic matter digestibility from 50 to 85 per cent and in protein content from 10 to 36 per cent (dry matter basis).

The accuracy of equation (1) for evaluating D is a function of n and of the standard deviation, s, of the constant C. Thus, if D and D_1 are calculated by using two values for the constant (C and C_1) differing by the standard deviation s, then

$$D = 100\left[1 - \frac{C}{n}\right], \quad D_1 = 100\left[1 - \frac{C_1}{n}\right],$$

and
$$D - D_1 \doteq 100\left[\frac{C_1 - C}{n}\right] = \frac{100s}{n}. \qquad (2)$$

A convenient means of assessing the accuracy of the proposed method of estimating digestibility is provided by equation (2), which shows that the greatest accuracy is obtainable at the highest concentration of fæcal nitrogen. When equation (1) was applied to the data from the digestibility trials mentioned above, it was found to yield results for D the agreement of which with those calculated from measurements of feed ingested and fæces voided were well within the limits of accuracy predicted by equation (2), provided n was not less than 3 per cent (equivalent to about 15 per cent of protein in the pasture consumed). When n was less than 3 per cent, however, the accuracy was not as high as equation (2) predicted, and the results were biased in such a direction as to indicate that $C = 0{\cdot}83$ was too high a value for the low-protein pastures.

Mitchell[4], from an analysis of data from pasture digestibility trials with sheep, has shown that the small variations of protein excreted in fæces per 100 gm. of pasture dry matter consumed are positively correlated with the protein content of the pasture. This provides an explanation of the bias noted above, and suggests that greater accuracy could be achieved in the calculation of D if some provision could be made for the nitrogen content of the pastures. The number of trials on low-protein pasture, however, was considered too small to warrant an attempt being made to carry this out.

In view of these considerations, the investigation was extended to include as much material from published work as could be obtained locally. From the results of one hundred and one digestibility trials[5], plus the data from the fifty-two trials already discussed, a value for C was calculated. This proved to be $0{\cdot}76 \pm 0{\cdot}113$. The pastures covered in this investigation were located in England, United States, South Africa and New Zealand. They ranged in organic matter digestibility from 48 to 85 per cent and in protein content from 5 to 36 per cent.

Further inspection of the data indicated that they could be divided conveniently into two groups: (A), 103 trials, in which the protein content of the pasture was 15 per cent or more; (B), 50 trials, in which the protein content of the pasture was less than 15 per cent. On this basis, C was found to be $0{\cdot}80 \pm 0{\cdot}081$ for group A and $0{\cdot}67 \pm 0{\cdot}120$ for B.

The results of the foregoing discussion suggest that the method proposed of calculating the digestibility of pasture by sheep is of fairly wide applicability both in terms of pasture types and geographical location. The most important factor contributing to the different values of C obtained appears to be the nitrogen content of the pastures, and although the differences between these values are not statistically significant, real differences may nevertheless exist. Some advantages might, therefore, be gained by using values of C_1 determined by the range of the nitrogen content to be expected in a pasture herbage under investigation.

From points made in this communication, the graph presented by Raymond may now be interpreted in terms of organic matter digestibility. Using $C = 0{\cdot}76$, the mean value obtained for all pastures studied, the nitrogen scale of his graph may be converted to a digestibility scale with a range from 69·6 to 81·0 per cent.

A New Theory of Phyllotaxis

A REVIEW of my book "La Théorie des Hélices foliaires multiples", which appeared in *Nature* of November 20, p. 798, does not give an objective view of its subject-matter.

In my opinion, the fundamental character of a law being its generality, a common phyllotaxic law should at least apply to all the angiosperms. Now, the numerous phyllotaxic theories, all of which rely on the idea of divergence, cannot be verified except in particular cases or in ideal examples where the mind corrects and adjusts Nature where it is judged imperfect. The leaf considered as a point, or the stem considered as a cylinder, are typical examples of this idealization.

Taking as my starting point cases where it is impossible to find constant divergence along the line which, going from leaf to leaf, forms a genetic spiral—cases where it is only possible to trace a spiral because one wishes to do so and so makes corrections, with a pretence of metatopy, in the position of almost half the leaf points—I have discovered a law concerning the position of leaves on stems which has not previously been recognized. It is based on the existence of series of leaves called leaf-helices. The plotting of these lines is not arbitrary, since the successive leaves in a leaf-helix are contiguous so far as the segments by which they extend along the stem are concerned. The leaf-helices are usually two in the dicotyledons, but vary in number (frequently three, sometimes one) in the case of the monocotyledons.

This interpretation offers a solution to numerous problems of morphology. It unifies the arrangement of leaves in spirals or in whorls, and explains the frequent change from one to the other on the same plant. It unifies the most diverse leaf arrangements and explains the stems of palms as well as cacti. It offers a new explanation of teratological phenomena present in leaf-bearing stems, and, in particular, fasciation. It offers a hypothesis on the nature of the growing-point; but I have also shown that experiment alone can demonstrate the value of the theory.

It is not reasonable of the reviewer to reduce the book to a hypothesis on the physiological constituents of the growing-point. Moreover, the way in which he has substituted, in the title and the matter of his text, the idea of leaf formation for the idea of phyllotaxis—which implies only the arrangement of leaves on stems—in order to criticize the absence of studies on growing-points, betrays confusion on his part. Moreover, readers will find that the points of view of the reviewer have been met in an article called "Hélices foliaires, point végétatif et stèle chez les Dicotylédones" which appeared in the *Revue générale de Botanique* (**54**, 49; 1947).

LUCIEN PLANTEFOL

La Sorbonne,
45 rue d'Ulm,
Paris V.
Dec. 5.

PROF. PLANTEFOL'S chief criticism of my review seems to be that I have taken as the most important feature of his book the conclusions concerning leaf formation at the apex which he has based on his observations of the relative positions of leaves or of their scars on mature stems. He claims that even apart from these conclusions his observations have value and lead to a law which solves various morphological problems. But his book and also his recent paper make it appear throughout that this law or theory, the theory of the foliar helices, was indeed intended as a causal theory of leaf formation. Thus, for example, on p. 195 of his book, in discussing *Lilium candidum*, he refers to the three foliar helices which he finds as being a "système fait de l'activité de trois centres générateurs de feuilles, entités douées chacune de propriétés mitotiques particulières, qui se transmettent de proche en proche suivant la ligne que trace l'hélice". I maintain, therefore, that I was right in regarding his theory of the foliar helices, supplemented by his theory of the apical organiser, as being essentially a causal theory of leaf formation at the apex, though based on observations made on mature parts of shoots. If he now proposes to regard this theory as being essentially only a descriptive rule, then how can such a descriptive rule concerning the positions of leaves on mature stems explain anything, or lead to anything more than a classification of facts ?

My criticism of the theory that leaves are formed along the foliar helices was that these helices are at best only one set arbitrarily selected from the two well-known sets of intersecting parastichies, or paths along which the bases of leaves or other lateral members are in contact. Prof. Plantefol claims that his helices are not arbitrary, since the bases of the lateral members are in contact along them. But so also are they in contact along the helices or parastichies of the other set which crosses the first set, as can easily be seen on a pine cone, for example; and there are no valid grounds for preferring the one set to the other. The same can be seen in the figures of bud sections in his recent paper, in which he marks the parastichies of one set as being his foliar helices, but ignores those winding round the apex in the opposite direction. Also there is no rule that the parastichies of either set are only two in Dicotyledons, though the number two is rather common for the reasons given before. So the theory is another theory of leaf formation along lines continuing parastichies into the apex, something like that of Church[1], but with the disadvantage that it is based on an arbitrary selection of parastichies. In addition, all such theories are in conflict with evidence now available from experiments on stem apices[2] which reveal no *leaf-forming* influences extending into the stem apex from below or obliquely below, but only effects *delaying* leaf-formation which are exerted by the young leaves just below the apex. The only indications of leaf-forming influences from below are at present those obtained by Weisse[3] in various ridged succulents: and those influences do not follow the parastichies but the nearly vertical ridges.

Threat of Disease in Tropical Crops

THE report by a committee of pathologists of three nations which has been inquiring into swollen shoot disease of cacao (His Majesty's Stationery Office, Colonial No. 236) contains matter of interest beyond the field of inquiry. Pathologists in the past have often been inclined to consider infection in a biological vacuum. The disease organism (assisted in the case of viruses by a vector) was regarded as an agent of destruction subject to no external conditions except those which might be imposed by pathologists.

This attitude has left its mark on the present report. It asserts that, "Drought, old age, lack of canopy, and poor soils have nothing whatsoever to do with it"—the disease. This is emphatic. But it is not a conclusion derived from experiments with swollen shoot of cacao. The genetically unstandardized condition of the cacao trees in West Africa would invalidate any experimental evidence that might be available on the question. None, in fact, is adduced by the committee.

In a word, there is no reason for supposing that the committee has discovered an exception to the biological law that external (as well as internal or genetic) conditions affect to a greater or less degree the incidence of every type of pest and disease of plants and animals.

On the other hand, the genetic variable is of the first importance, and this is recognized by the committee. It points out "the development of varieties resistant to infection would be an ideal solution of the problem". But it omits this fundamental principle from its conclusions; and it has postponed the application by a dangerous misstatement: "It takes *many* years to obtain seed from a single crossing of two parents". In fact, it takes *two* years; and this time could be reduced by experimental improvement of growing conditions. Hence, the committee concludes, "This is a long term problem without any immediate practical significance". This is again emphatic. But what does it mean ? It means that in prosperity plant breeding had no immediate significance. In disaster it has no practical significance. Thus in cocoa as in all other British tropical crops (except cotton) the ideal solution, the fundamental solution, has still to be treated as a subsidiary matter of no urgency. And there is no plan for attempting it. This is the immediate and practical significance of the report on swollen shoot in cacao.

ROYAL SOCIETY OF CANADA

ANNUAL MEETING

THE 1948 meeting of the Royal Society of Canada was held at Vancouver (June 14–16) and Victoria (June 17) in British Columbia. This was the first time in its sixty-six years of existence that the Society has met west of Winnipeg, and for a while it seemed that the serious floods of the Thompson and Fraser Rivers would force the cancellation of the sessions here reported.

A general meeting of the Society, at which new fellows were introduced, was held on the morning of June 14. Those elected to the Scientific Sections of the Society were as follows: Section 3 (chemical, mathematical, and physical sciences), John David Babbitt, Adrien Cambron, Frank Thomas Davies, Richard Norman Jones, Robert Lloyd McIntosh and George Michael Volkoff; Section 4 (geological sciences), John Fletcher Caley, Edward Darwin Kindle and John Tuzo Wilson; Section 5 (biological sciences), James Kenneth Wallace Ferguson, F. E. J. Fry, Nathaniel Hew Grace, Rene Pomerleau, Frederick Smith and Omond McKillop Solandt.

On the evening of the same day the Flavelle Medal was presented to Margaret Newton, who was for a long time associated with the Dominion Rust Research Laboratories at Winnipeg, and whose work on the fungi attacking wheat has been of such importance in Canada. The Lorne Pierce Medal was awarded to Gabrielle Roy, author of "Bonheur d'Occasion", and the Tyrrell Medal to Canon Groulx. The president of the Society, Dean W. P. Thompson, of the University of Saskatchewan, then delivered his presidential address on "Mutations". This proved to be a masterly treatment of a difficult subject, made intelligible to a general audience. The final meetings were held in Victoria on June 17.

Officers for the session 1948–9 were elected as follows: *president*, Dr. Gustave Lanctot; *vice-president*, Dr. J. A. Pearce; *honorary secretaries*, Dr. F. J. Alcock and Dr. Seraphin Marion; *honorary treasurer*, Dr. L. E. Howlett; *honorary editor*, Dr. G. W. Brown.

Section 3: *President*, Dr. J. S. Foster; *vice-president*, Dr. C. S. Beals; *secretary*, Dr. H. G. Thode.

Section 4: *President*, Dr. Victor Dolmage; *vice-president*, Dr. T. L. Tanton; *secretary*, Dr. George Hanson.

Section 5: *president*, Dr. A. H. Hutchinson; *vice-president*, Dr. T. W. M. Cameron; *secretary*, Dr. R. D. Gibbs.

In Section 3 the presidential address, delivered by Dr. E. W. R. Steacie, was on "Photosensitization", an illuminating review of processes involved in photochemical reactions. Two symposia, of interest to the whole section, were held, at the first of which, on "Chemical Kinetics", four papers were presented: "Reactions of Atomic Sodium", by Dr. D. J. LeRoy; "Halogen-Sensitized Photoreactions", by J. W. T. Spinks; "The Thermal Decomposition of Complex Molecules", by C. C. Coffin; and "The Radiation Chemistry of Aqueous Solutions", by F. H. Krenz. LeRoy studied the subsequent reactions of the free radicals invariably produced in the primary reaction between atomic sodium and various halides. Particular attention was given to the free vinyl radicals produced in the reaction of atomic sodium with vinyl chloride and vinyl bromide. When using hydrogen as a carrier for atomic sodium, spurious results may sometimes arise. Reactions due to atomic hydrogen were possible in such a system as one containing sodium hydride, hydrogen and ethane. Spinks, using spectroscopic evidence which indicated whether absorption of light by the halogen results in the formation of atoms or excited molecules, together with kinetic studies, described the mechanisms of a number of photochemical reactions sensitized by chlorine, bromine and iodine. Coffin discussed the effect of molecular structure on the activation energies, frequency factors, etc., of certain decompositions, particularly those of methylidene diacetate, peraldehyde and their homologues decomposing in the gaseous state at temperatures low enough to ensure the absence of free radical complications. F. H. Krenz described work to determine the 'indirect effect' on biological systems of the hydrogen atoms and hydroxyl radicals produced in aqueous solutions subjected to radiation. The effect was studied through the properties of irradiated water. Evidence was obtained for the production of long-lived activity in irradiated water, which may be due to electronically excited 'polymers' of water, and which may account for the efficiency of the 'indirect effect'.

At the second symposium, on "Nuclear Physics", papers were presented as follows: "Experiments with Neutrons", by Dr. B. W. Sargent; "The $4n+1$ Radioactive Series", by E. P. Hincks; "Variations in Isotope Content of Light Elements", by H. G. Thode; "Progress Reports on McGill Cyclotron Project", by J. S. Foster; "Nuclear Physics Programme of the University of British Columbia", by G. M. Shrum. Sargent discussed determinations of the half-life of photoneutrons, measured after shutting down a low-powered atomic pile, following different lengths of activation. Instrumentation had to be improved to allow for the large range of intensity encountered. Thode described experiments using a mass spectrometer to measure the isotopic constitution of boron obtained from various mineral deposits in the earth's crust. This investigation involved the use of boron trifluoride gas prepared from boric acid. Both BF_2^+ and B^+ ions were considered in the determination of the boron-11/boron-10 ratios. Automatic recording equipment gave the relative values of these ratios for the different samples with a precision of ± 0·1 per cent and an absolute accuracy of ± 0·5 per cent or better. The ratio was found to vary from 4·27 to 4·42, depending on the source of the boron. Corresponding variations in the chemical atomic weights have been calculated using the latest mass data for the isotopes. For the remainder of the programme Section 3 was divided into subsections, and seven papers were given in the subsection on chemistry, twenty-eight papers in general physics and mathematics, and fifteen in astrophysics and geophysics.

In Section 4 the presidential address, delivered by Dr. F. J. Alcock, was on "Problems of New Brunswick Geology". The rocks of New Brunswick range in age from Precambrian to Triassic. Deformation and intrusion took place in the Precambrian, the Devonian and the Carboniferous ages; and the Triassic rocks have been extensively faulted. Volcanism was recurrent. Detailed study in local areas has established the main facts of the geological story of the Province, but there are many places where the absence of fossils, the metamorphosed character of the rocks and the predominance of volcanic members present problems of correlation. The paper gives the conclusions reached by the author as a result of field work carried out in that region over the last quarter of a century, and is a most useful summary for all who are interested in the Appalachian geology of eastern Canada.

Thirteen papers were presented, and a lively discussion on the origin of granites followed the presentation of a paper entitled "Back to Logan" by H. C. Cooke, in which he briefly reviewed the development of theories of granitization and concluded, in harmony with an early interpretation by Sir William E. Logan, that many bodies in granite in Canada have been thus formed. Problems in the interpretation of age relationships of granites were dealt with in "Extent of Proterozoic Granite Intrusions in the Western Part of the Canadian Shield", by J. F. Henderson, and "The Relation of the Granite and the Seine Series at East Shoal Lake, Ontario", by E. L. Bruce and J. S. Ross. "Recent Data on the Nature and Origin of some Iron Deposits in the Canadian Shield", by E. S. Moore, gave information about Algoma and Labrador, where exploration for iron ore is in progress. "An Occurrence of Boron Minerals at Silver Harbor, Ontario", by T. L. Tanton and Eugene Poitevin, described a vein in which danburite has been found for the first time in Canada. "Radioactive Nodules in Sediments of the Sibley Series, Nipigon, Ontario", by T. L. Tanton, reported the results of a recent study of nodules in the red beds of the Sibley series, which were observed to be lithologically similar to uranium-bearing nodules in the Permian red beds of Devon, England. "Eoeponidella", by R. T. D. Wickenden, described a new genus of foraminifera. A paper of general interest to the members of the Section was "The Geological History of Greater Vancouver", by M. Y. Williams.

Section 5 had a very crowded programme with more than fifty papers listed, and for some sessions the Section split into separate botany, zoology and medical sciences subsections. The address of the president, Dr. E. Gordon Young, of Dalhousie University, was entitled "Canadian Dietary Patterns, 1937–1947", and constituted a survey of work on diets in Canada, particularly with reference to the war years. One session was devoted to a symposium on atomic energy in relation to biology. Contributors to this were an introduction by G. M. Shrum; "Problems of Handling and Measuring Stable Isotopes", by H. G. Thode; "Measurement and Handling of Radioactive Isotopes", by A. J. Ciprianni; "Precautions for Workers Using Radioactive Isotopes", by G. H. Guest; "Botanical Problems", by J. W. T. Spinks; and "Radiation Genetics", by C. E. Ford.

It was natural that sessions held in British Columbia would include several papers on salmon and other fish. "Mortality in Pink Salmon" was discussed by A. L. Pritchard; "Fecundity and Mortality in Pacific Salmon" and "Migrations and Spawning of Sockeye Smolt" by R. E. Foerster; and "Movement of Fundy (Atlantic) Salmon" by A. G. Huntsman. Papers dealing with the butter sole and the lemon sole were read by J. L. Keith Stuart Ketchen, and A. L. Tester spoke on "Catch Limitations for Regulation of the B.C. Herring Industry".

SOLUBILITY OF INDUSTRIAL SILICEOUS DUSTS

By Dr. P. F. HOLT
University of Reading
AND
Prof. H. V. A. BRISCOE
Imperial College of Science and Technology, London

THE theory that tissue damage in silicosis is caused by silicic acid formed by solvent action of the plasma on inhaled particles stimulated the study of the solubility of airborne siliceous dusts and of the materials which give rise to them. The investigation of the solubility of mineral silicates is complicated by their peculiar properties. When a powdered siliceous mineral is shaken with water, the solution may contain particles which range from large colloidal particles to simple ions; and different workers have determined the solute gravimetrically after filtration[1], gravimetrically after ultracentrifuging[2] or colorimetrically as the silicomolybdate complex which is formed both with simple and with more complex colloidal silicic acids. King and McGeorge[3] consider that the colorimetric method is most likely to give figures representing physiologically active 'soluble silica'.

A mineral suspension does not reach equilibrium with the liquid phase within a reasonably short time, and a comparison of the solubilities of two substances must normally be made by comparing the quantities of solute after a fixed time. The apparent solubility depends on the temperature, the particle size of the dust and on the ratio of dust to solvent[4]. Since the extraction of dust particles in the lung by constantly changing lymph is so complex a process that any true imitation is impossible, investigators have attempted to compare solubilities under simplified fixed conditions, and with simpler solvents. For example, Briscoe and others[4] investigated the effect of water, Whitehouse[5] used 1 per cent sodium carbonate solution, Emmons and Wilcox[6] used plasma, while King and McGeorge[3] used ascitic fluid, similar to plasma but with less protein.

Experiments already reported[4] have shown that airborne industrial flint dusts have a relatively high silica-solubility in water at 100° C., and this solubility increases greatly as the particle-size is reduced. Under the same conditions industrial cement dusts show a much smaller solubility which varies but little with particle-size. Since flint produces silicotic lesions and cement does not, these results were accepted as supporting the general theory that dangerous dusts have a higher solubility than those which have no pathological action. Further investigation has shown that the solubility values are widely influenced by a number of additional factors. For example, the proportion of silica which dissolves

Table 1. Solubility of flint dusts in water at 100° C.

	Dust : water ratio	Raw flint	Calcined flint
Composition of dust			
SiO_2	—	76·0	79·1
CaO	—	12·7	6·5
Composition of solute			
SiO_2 (mgm. from 1 gm. dust)	1 : 100	3·9	1·2
	1 : 1000	8	24
CaO (mgm. from 1 gm. dust)	1 : 1000	12	64

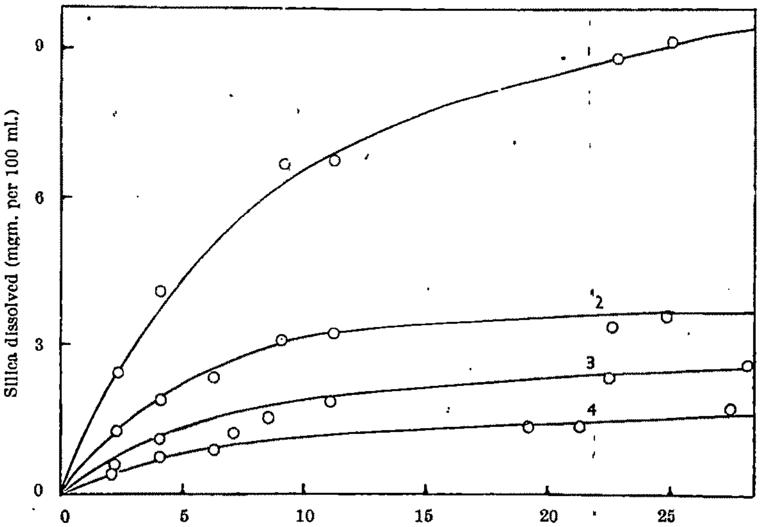

Fig. 1. Effect of carbon dioxide on the solubility of flint dust. (1) Ignited sample + CO_2; (2) normal sample + CO_2; (3) normal sample + air: (4) normal sample + air free from CO_2

from these industrial dusts depends markedly on the gravimetric ratio of dust to water, as is well illustrated by the figures for raw and calcined flint dusts given in Table 1.

Carbon dioxide will also affect considerably the solubility of dusts. Calcium is present mainly as carbonate in raw flint dust, and as carbonate, silicate and sulphate in calcined flint dust. The silica solubility figures shown by the dusts in the presence of carbon dioxide may be influenced by one or more of the following factors:

(*a*) Calcium silicate is decomposed by carbon dioxide, resulting in an increase in the silica which passes into solution, as is shown by re-igniting a sample of calcined flint dust, thus converting much of the calcium sulphate into calcium silicate. The solubility is much increased (Fig. 1).

(*b*) Carbon dioxide reduces the solubility of lime-free flint.

(*c*) Calcium carbonate increases the solubility of flint. The effects (*b*) and (*c*) were demonstrated by using calcined flint dust freed from calcium by washing with hot hydrochloric acid and water. Three 1-gm. portions of this sample were extracted with 100 ml. of water through which air, air freed from carbon dioxide, and carbon dioxide respectively were bubbled. The solubility values given after three days are compared in Table 2 with those obtained when the original flint dust was similarly extracted. It is apparent that, whereas the original dust is considerably more soluble in the presence of carbon dioxide than in its absence, the reverse is true of the acid-treated sample. Moreover, the solubility in the absence of carbon dioxide is much greater after acid extraction. King[7] found that the solubility of a number of dusts in Ringer solution was considerably increased after acid treatment. The addition of calcium carbonate, a substance which is present in most industrial dusts, to calcium-free flint dust increases its solubility to a maximum value in the presence of carbon dioxide; further addition lowers the solubility (Table 3).

Table 2

	SiO_2 (mgm.) dissolved from 1 gm. of dust		
	CO_2	Air	CO_2-free air
Acid-extracted dust	0·2	4·3	8·6
Untreated dust	2·0	0·9	0·6

The curves in Fig. 2 are plotted from data obtained by following the silica-solubility of calcined flint and cement dusts when extracted with water in the presence of carbon dioxide at 18° C. In both cases the water was replaced periodically. The rates of solution in the first and fourth extractions are illustrated. Flint shows a progressive decline in the rate of solution with each successive extraction, but the opposite is true for cement. Carbon dioxide increases the silica-solubility of cement to a value comparable with that of flint, and the value is increased in subsequent extractions until it is considerably higher than that of flint.

The experiments recorded indicate that solubility values can be greatly altered by variation in the conditions of extraction. Since the composition of the dust, particularly with respect to the form and concentration of the calcium compounds it contains, largely affects the solubility, a change in composition resulting from the removal of the more soluble constituents will alter the silica-solubility values during subsequent extractions. *In vivo*, the fluid affecting the particles is continually renewed, and possibly the solubility *in vivo* might be more nearly deduced from a study of the curves obtained by repeated extractions than from any single solubility

Table 3

$CaCO_3$ added (mgm. per 1 gm. flint)	Dissolved SiO_2 (mgm. per 100 ml.)
0	0·6
18	1·9
93	4·1
187	5·9
300	5·7
500	5·1
1000	4·3

——— Cement; - - - - flint

determination. Simple comparison of the solubilities of dusts using fixed conditions may give misleading results, and the correlation of solubility with pathological action by *in vitro* means will require a much more exhaustive study than has so far been attempted. In experiments designed to show the dissolution of dusts in the body, which will be reported elsewhere, cement has shown a relatively high solubility as compared with flint, sand (harmful dusts) and carborundum (harmless).

FIXATION OF FREE NITROGEN BY BARK BEETLES

By PROF. J. PEKLO and J. SATAVA
Prague

IN 1912 and 1916 one of us isolated *Azotobacter* (*A. Sulcii*) from Aphides[1,2]. More recently, L. Tóth and others[3] proved by micro-Kjeldahl determinations that species of *Rhynchota* (Aphides, etc.) can also rapidly and considerably increase their nitrogen content by utilizing atmospheric nitrogen, though Smith[4] has not been able to confirm these results. This year, we made more progress in studying nitrogen fixation by the bark beetle, *Ips*, which has done much damage lately in Czech spruce forests.

The larvæ were mostly collected in mountain forests. Over successive intervals they were crushed with oxalacetic acid solution or similar reagent, oven-dried at 100° C., and subjected to Kjeldahl estimations. Using large amounts (0·5–0·8 gm.), as described by Csaky and Tóth[5], did not give good results. Samples often showed a decrease in nitrogen compared with the controls. Hence, only small numbers of larvæ (30–50) were used. It was also found that results depended on the age of the larvæ. Half-grown (approximately three weeks old) larvæ fixed atmospheric nitrogen, whereas fully fed and fat ones often showed a decrease. This agrees with our view[6] that the microbial symbionts of *Ips*, which occur in the peripheral (so-called adipose) tissue, soon find their way into the alimentary canal, where they are digested. Pupæ and young beetles do not fix nitrogen.

Though they were often found under the bark in great quantities, it was found inadvisable to collect larvæ directly in the forest. It was best to collect large samples (10–15 kgm.) of the infested bark and to isolate the larvæ in the laboratory, grouping them according to size. Even so, it was sometimes difficult to ensure that only one species of *Ips* was under examination, since several can occur together.

In the first series, using *Ips amitinus* L., from the Jizerské Mountains, in July 1948, the reagent used was either: (*A*) 0·088 per cent oxalacetic acid, 0·5 per cent dextrose, 0·7 per cent sodium chloride, 5·4 per cent dipotassium hydrogen phosphate; or (*B*), which contained 0·2 per cent succinic acid in place of the oxalacetic acid and 9 per cent of phosphate. Both had *p*H = 7·2, and 3 c.c. were used with each sample of larvæ.

Sample	Dry weight (gm.)	Per cent N in dry material	Duration of fixation	Increase of N
1	0·2466	1·7	control	—
2	0·2480	1·92	13 hr.	13 per cent
3	0·2473	1·81	24 ,,	6 ,,
4	0·2552	2·08	48 ,,	21 ,,
5	0·3590	1·52	control	—
6	0·3727	1·46	13 hr.	decrease
7	0·3634	1·61	24 ,,	6 per cent
8	0·3820	1·57	48 ,,	—

Reagent *A* was used for the first four samples, and reagent *B* for the others. Oxalacetic acid is considered preferable to succinic acid for this work.

Further results were obtained using samples of the same species from the same locality. Small larvæ and small amounts were used, but with slightly different reagents. Reagent *C* contained 0·1 per cent of aspartic acid and had a *p*H = 7·2; reagent *D* contained 0·0669 per cent of oxalacetic acid, 1 per cent dextrose and 12 per cent phosphate besides the sodium chloride; its *p*H = 7·7. Reagent *E* was the same as *A* except for dextrose (1·5 per cent) and 5·4 per cent K_2HPO_4, *p*H = 7·0. Reagent *F* contained 0·132 per cent of oxalacetic acid and the higher amounts of dextrose and phosphate, *p*H = 7·0.

In the following samples, reagent *C* was used for 1 and 2; reagent *D* for 3 and 4; reagent *E* for 5 and 6; and *F* for 7 and 8.

Sample	Dry weight (gm.)	Per cent N in dry material	Duration of fixation	Increase of N
1	0·0922	2·89	control	—
2	0·0923	3·19	12 hr.	10 per cent
3	0·0950	3·46	control	—
4	0·0885	3·64	12 hr.	5 ,,
5	0·1804	1·78	control	—
6	0·1798	1·84	12 hr.	3 ,,
7	0·3816	0·84	control	—
8	0·2572	1·33	12 hr.	60 ,,

A third series of tests was made with *Ips typographus* L. and *Ips* (*Pityogenes*) *chalcographus* L., from Broumov Rocks (August 1948), using an oxalacetic acid reagent.

Sample	Dry weight (gm.)	Per cent N in dry material	Duration of fixation	Increase of N
1	0·1919	1·46	control	—
2	0·1872	1·39	14 hr.	—
3	0·1819	1·12	24 ,,	—
4	0·2016	1·59	control	—
5	0·2086	1·67	14 hr.	increase
6	0·2142	1·57	24 ,,	—
7	0·1944	1·63	48 ,,	increase
8	0·2024	1·28	control	—
9	0·1887	1·11	14 hr.	—
10	0·1929	0·98	control	—
11	0·1863	1·09	14 hr.	increase 11 per cent

In the first three samples, the *I. typographus* were very small; small to medium specimens were used in samples 4–7 and medium ones in 8 and 9. The last two samples were young larvæ of *I. chalcographus*. In the first three samples the adipose tissue with symbionts had probably not developed, hence no nitrogen fixation. In the other samples of *I. typographus* the larvæ were probably too old, hence only a small increase or decrease of nitrogen was observed.

In the last two, *I. chalcographus* definitely fixed free nitrogen.

Another series of samples, also collected at Broumov in August 1948, were similarly treated with the same reagent, samples 1–6 with 2 c.c. and 7–11 with 3 c.c. *I. typographus* larvæ longer than 4 mm. were used in samples 1 and 2; *I. chalcographus* (small, young larvæ up to 2 mm.) was used in samples 3–6; samples 7 and 8 were medium-sized larvæ of the same species (up to 3 mm. in length), and samples 9–11 consisted of larvæ up to 5 mm. long.

Sample	Dry weight (gm.)	Per cent N in dry material	Duration of fixation	Increase of N
1	0·1597	1·36	control	—
2	0·1604	1·44	13 hr.	about 6 per cent
3	0·1457	lost	—	—
4	0·1414	1·09	13 hr.*	—
5	0·1492	1·27	26 ,,	6 ,,
6	0·1423	1·33†	72 ,,	21 ,,
7	0·2211	1·39	control	—
8	0·2314	1·59	13 hr.	14 ,,
9	0·2348	1·43	control	—
10	0·2388	1·41	13 hr.	—
11	0·2356	1·39‡	26 ,,	—

* Control. † In contrast with 4. ‡ Larvæ too old.

Thus, on the whole, in all four series there is an increase in the nitrogen content of the larvæ, agreeing with our cytological considerations. This also coincides with the rapid breeding of these insects, though it is not so remarkable as with Aphides. It affords an explanation of the damage caused by *Ips*, and the question arises whether this behaviour can be controlled and even put to some use.

More than a hundred eggs as well as many larvæ were used in order to isolate the symbiotic organisms. In the adipose tissues it is mainly *Torulopsis* (*Cryptococcus*), an extremely variable organism, in contrast with previous experience. In addition, many strains of *Candida* were isolated as well as various species of bacteria, some resembling *Azotobacter*.

MUSHROOM RESEARCH STATION AT YAXLEY

By Dr. R. L. EDWARDS
Director of Research

RESEARCH on some of the problems of mushroom growing has been carried on for many years, particularly in France and in the United States. Two aspects have received special attention —the chemical and microbiological changes in horse manure during composting, and the fungus diseases of mushrooms and mushroom beds. The principal British work on mushroom cultivation is that of Ware on diseases and of Pizer on horse-manure composts. Recently the mechanization of transport has caused an increasing shortage and rise in price of horse manure, and this has become a major problem. Research on synthetic composts was in progress in the United States twenty years ago, and several formulæ have been published; but many of the materials used are not available in Great Britain. Since the end of the War, American growers and research workers have devoted more attention to methods of using the available supplies of horse manure more economically, and to mechanization of their cultural operations. Synthetic composts are not widely used. Some work on synthetic composts was done in France during the 'thirties, but horse manure is still the only medium used commercially.

In 1945 a group of British mushroom growers decided to set up their own research station at Yaxley, with the development of a commercially satisfactory synthetic compost as the main problem. A laboratory, two test-houses, and a covered turning shed were built, and work started in 1946. Six experimental crops have been grown during the past three years, and the main requirements for making a productive synthetic compost from wheat straw have been established. Small-scale tests on a commercial farm have given a yield comparable with the best obtained from horse manure.

As a result of consultations between the Mushroom Research Association, Ltd., which has financed the research station until now, the Mushroom Growers' Association (a specialist branch of the National Farmers' Union) and the Ministry of Agriculture, arrangements are being made for the Research Association to receive a grant from the Ministry and to publish all its results.

Each main cropping-experiment now includes twenty-four composts of about half a ton each, made up side by side in two rows, and separated by iron sheets, so that aeration and losses of heat and moisture are similar to those occurring in one long stack of compost. In this way the replicated comparisons and factorial experiments familiar in agricultural research can be carried out. Analyses and microbiological examinations of the composts are made at suitable stages. Some of the results obtained in this way are likely to interest workers on agricultural composts.

The main nutrients studied are nitrogen, phosphorus, potassium and calcium. The source of nitrogen is very important, organic nitrogen giving higher yields than the inorganic forms so far tested. An empirical mixture of twelve trace-elements has quite a pronounced effect; one problem for the future is to determine which of these are essential and in what proportions. Preliminary experiments with growth substances suggest that further work in this field may give results of practical value, in addition to its scientific interest. The number of mushrooms produced has been increased in several experiments, and earlier fruiting has been obtained.

Variations in the depth of beds and in the intervals at which spawn is sown have quite marked effects on the time of fruiting and on yield. In the course of these experiments the number and size of mushrooms produced are recorded daily, and some measurements of their rate of growth and the relation between dimensions and weight are made. In several instances factors affecting the number of mushrooms produced have been distinguished from those affecting their size, and this work will add much to our knowledge of the appearance of mushrooms in flushes, the opening of the veil, which is subject to considerable variations, and the exhaustion of mushroom beds. These fundamental aspects of mushroom 'macrobiology' have been almost entirely ignored in the past, and their elucidation is of scientific and practical interest.

VELOCITY OF LIGHT AND MEASUREMENT OF DISTANCES BY HIGH-FREQUENCY LIGHT SIGNALLING*

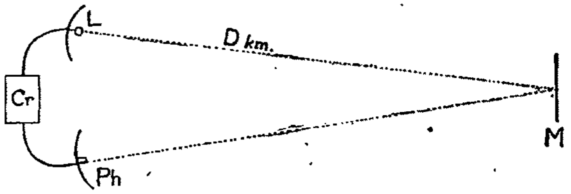
By E. BERGSTRAND

Geographical Survey Office, Stockholm

FIZEAU'S principle of determination of the velocity of light can be used for the measurements of lengths. In modern form an arrangement according to this principle is shown in Fig. 1.

L is the source of light, having a spherical mirror to collect the light in a beam. The source is influenced by high-frequency tension from the crystal-controlled oscillator *Cr*, and thus the intensity of the light emitted varies with the frequency of the oscillator. *M* is a plane mirror, which reflects back the light to the phototube *Ph*. The phototube gets its operating tension from the oscillator *Cr*. Accordingly, the sensitivity of the tube varies with the same frequency as the intensity of the emitted light. As the rapid blinks of light take a certain time to cover the distance to *M* and back again, the moments of high sensitivity of the tube will be more or less timed to the incoming blinks, depending on the distance *D*. Fig. 2 shows how the recording current directed by the phototube depends on the distance *D*.

Fig. 1



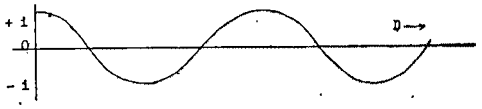


Fig. 2

A low-frequency alternating phase displacement of 180° of the high-frequency light variations makes the current exactly symmetrical with respect to the zero-line. By this means we get sharply marked positions of the mirror where the current is zero. The distance between the zero positions depends on the frequency of the oscillator *Cr*. In the actual apparatus, the frequency is 8·3 Mc./sec., corresponding to a wave-length λ of 36 metres. Thus the current becomes zero every ninth metre in accordance with the expression

$$D = K + \frac{2N - 1}{8} \cdot \lambda,$$

where *D* is the distance to be measured, *K* is a constant, depending on the apparatus used, λ is the wave-length, depending on the frequency and here being 36 metres, *N* is a whole number + 1, 2, 3, 4, ... Usually *N* is known from an approximate knowledge of *D*; if not, it may be determined by variation of λ. The values of *D* corresponding to $N = 1, 2, 3, \ldots$ are constant to the same degree as the frequency is constant, that is, to one part in ten millions; they depend also on the accuracy with which the atmospheric conditions are known. Thus the influence of temperature is 0·9 cm. per degree C. and 0·4 cm. per millibar air pressure, for a distance *D* of 10 kilometres.

In the field, the mirror *M* usually is not placed exactly at a zero-point. We then decrease the frequency slightly from its 'normal' value. The farthest zero-point glides out and passes the mirror. Just then the photo-current changes its direction and passes through zero. We now read off the change of frequency and get the distance of the mirror from the farthest 'normal' zero-point. In this way we get the extreme value of the distance to be determined. The other end is fixed in a similar way. Here we use the value of *D* for $N = 1$. This distance, about 1 metre, is very constant. By means of a variable loop of light, it can be determined or controlled. To get the main constant of the apparatus, the first determination is made on a known base-line.

At a value of *D* of 9 km., the sensibility of adjustment commonly was 0·4 cm. as a mean error of six determinations during a quarter of an hour. Measurements on different days showed a maximum divergence of 3 cm.

Knowing the frequency, we determined the velocity of light *in vacuo* to be 299·796 ± 2 km. per sec. We intend to make further measurements in March; therefore, the values given above should not be considered as definite.

A.G.A., Stockholm, intend to manufacture the 'geodimeter' for sale.

PHOTOMETRY OF THE CONTINUOUS SPECTRUM

PROF. W. M. H. GREAVES, president of the Royal Astronomical Society, delivered his presidential address on February 14, 1948, to the Society at Burlington House, selecting as his topic "The Photometry of the Continuous Spectrum". As Prof. Greaves pointed out at the beginning of his address, he was encouraged to make the attempt of presenting a survey of the subject by the consideration that it "can be used to illustrate the way in which Natural Knowledge is advanced by an interplay between observational and theoretical investigations". The address involves so many technical matters and is so comprehensive that no attempt can be made in this short notice to deal with it in detail; and those who are specially interested in the subject should study the paper itself (*Mon. Not. Roy. Astro. Soc.*, **108**, No. 1; 1948).

A general description is given of the kind of measurement which is undertaken in this comparatively new technique and also of the relation of this technique to that of classical photometry; after this there is a review of the theoretical work on spectral energy distribution which has taken place during the last two decades. The theory of the radiative equilibrium of stellar atmospheres had been independently developed by Lindblad and Milne, and, on the assumption that the stellar absorption coefficient did not vary with wave-length, Milne showed that the stars would radiate like black bodies. The calculated values for the sun's centre-limb contrast, which agreed well with the available data, seemed to substantiate this view, and the theory gave a definite set of temperatures—those of the Fowler–Milne scale—which were approximately identified with colour temperatures. The well-known work of Greaves, Davidson and Martin at Greenwich on the gradient difference between stars of spectral types $B0$ to $B3$ and stars of spectral type $A0$ showed a colour-temperature of 18,000° for $A0$-stars at a wave-length of 5000 A. as against the Fowler–Milne value of 10,000°; and it was necessary to discard Milne's provisional assumption that the stellar absorption coefficient did not vary with wave-length.

Reference is made to the advances which attended the work of McCrea, who calculated the emergent radiation for a model star composed entirely of atomic hydrogen, and of Pannekoek, who independently repeated McCrea's investigations, taking into account the contribution of metallic atoms in the stellar atmospheres. Also dealt with is the observational progress which was made during 1934–39 through the work of Barbier, Chalonge and their collaborators at Jungfraujoch, of Kienle and his colleagues at Göttingen, and R. C. Williams at Ann Arbor. Many others matters are included in the address, and towards the end Prof. Greaves expressed his personal opinion that, though the existence of intrinsic reddening in addition to space reddening has not been absolutely established, the balance of evidence favours the view that reddening by interstellar scattering is not the only process involved. Before attempting the task of interpretation, further measures are very desirable, and in particular the study of the variation of gradient excess with wave-length from the near infra-red to the near ultra-violet.

RUBBER RESEARCH INSTITUTE OF THE DUTCH EAST INDIES

THE Rubber Research Institute of the Dutch East Indies at Buitenzorg, Java, has recommenced publication after the delay of several years caused by the Japanese occupation, and a number of its recent reports contain points of interest.

Publication No. 38 shows that rubber obtained immediately after tapping the tree is readily soluble in petroleum ether, but on standing in the light it gradually becomes insoluble, especially if stored in the form of latex. These changes naturally complicate the supposed distinction between 'sol' and 'gel' rubber.

Publication No. 39 emphasizes the important bearing which the method of preparation of rubber has upon the physical properties of the final vulcanized article, especially in respect of water absorption and tension strength in the wet state; for example, whole-latex rubbers are much stronger when dry than when wet.

A study of the nature of the naturally occurring antioxidants in rubber latex (Publication No. 54) has shown that the amino-acids have a remarkably powerful antioxidant action. The spontaneous coagulation of *Hevea* latex has frequently been believed to result from progressive lowering of *p*H, but it still occurs even when the *p*H is kept constant, and work done in Java (Publication No. 58) suggests that the removal of magnesium ions, as a fatty soap, is the main cause of coagulation.

The vexed problem of the value of incorporating rubber powder in roadways receives a contribution in Publication No. 61, where it is shown that the durability of bituminous coatings in Java is much improved by the addition of rubber powder.

Some of those who use raw rubber have for long maintained that the 'fine hard Para', produced under primitive conditions in Brazil, is of superior quality to that produced on plantations. This controversy will presumably be revived by the report, given in Publication No. 62, that smoked sheets produced under primitive conditions in West Borneo may be of superior quality to those produced by native labour, following modern practice, in south Borneo.

The marked differences between fresh latex and old latex, some of which were commented on above, are responsible for an interesting development which is fully described in Publication No. 68. When old vulcanized latex is coagulated, a continuous coagulum is obtained; but if fresh latex is used for the vulcanizing process, and the product is then coagulated, the coagulum is not coherent and forms a powder, known as 'Mealorub', on drying. This very economical method of producing a powdered rubber will be watched with considerable interest, especially from the point of view of its use as a means of preventing the flow of road bitumens in hot weather, and as a means of binding certain types of road aggregates.

R. G. NEWTON

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, February 28

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 4.45 p.m.—Prof. C. Rimington: "Haem Pigments in Nature".* (Further Lecture on March 7.)

INSTITUTION OF THE RUBBER INDUSTRY, MANCHESTER AND DISTRICT SECTION (at the Engineers' Club, Albert Square, Manchester), at 6.15 p.m.—Dr. L. R. G. Treloar: "Rubber Physics applied to Engineering Problems".

CHEMICAL SOCIETY, EIRE SECTION (joint meeting with the UNIVERSITY COLLEGE OF DUBLIN CHEMICAL SOCIETY and the WERNER SOCIETY, in the Department of Chemistry, University College, Dublin), at 7.45 p.m.—Prof. T. Dillon: "Researches on the Chemistry of the Algæ".

CHEMICAL SOCIETY, OXFORD SECTION (joint meeting with the ROYAL INSTITUTE OF CHEMISTRY, in the Physical Chemistry Laboratory, Oxford), at 8.15 p.m.—Mr. C. S. Robinson: "Research and Productivity in Industry" (Alembic Club Lecture).

Tuesday, March 1

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Mr. R. B. Freeman: "The Life of Fleas".*

MANCHESTER GEOGRAPHICAL SOCIETY (at the Geographical Hall, St. Mary's Parsonage, Manchester), at 6.30 p.m.—Mr. T. Yeldham Unwin: "A Tale of Two Cities and other Places".

Wednesday, March 2

INSTITUTION OF ELECTRICAL ENGINEERS, RADIO SECTION (at Savoy Place, Victoria Embankment, London, W.C.2), at 5.30 p.m.—Mr. E. C. Cherry: "The Analogies between the Vibrations of Elastic Membranes and the Electro-magnetic Fields in Guides and Cavities".

UNIVERSITY OF LONDON (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Dr. Tore Levring (Göteborg): "Submarine Daylight, Photosynthesis and Vertical Distribution of Marine Algæ".* (Further Lecture on Friday, March 4.)

MANCHESTER METALLURGICAL SOCIETY (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Mr. C. G. Conway: "Metallurgical Problems involved in the Manufacture of Components for Jet Engines".

Thursday, March 3

ROYAL SOCIETY (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

CHEMICAL SOCIETY, NORTH WALES SECTION (in the Edward Davies Chemical Laboratories, Aberystwyth), at 5 p.m.—Dr. E. A. Moelwyn-Hughes: "The Liquid State".

Royal Meteorological Society (in the Lecture Theatre, Science Museum, Exhibition Road, London, S.W.7), at 6 p.m.—Prof. Gordon Manley: "British Climatic Fluctuations since Queen Elizabeth's Day".

Institution of Civil Engineers, North-Western Section (at the Engineers' Club, Albert Square, Manchester), at 6.30 p.m.—Mr. H. J. B. Harding: "Site Investigations, including Boring and other Methods of Surface Exploration".

British Institution of Radio Engineers, North-Western Section (in the Reynolds Hall, College of Technology, Manchester), at 6.45 p.m.—Mr. M. A. Alexander: "Some Radar Applications".

Leeds Metallurgical Society (in the Chemistry Department, The University, Leeds), at 7 p.m.—Mr. E. W. Colbeck: "Metallurgical Problems in the Field of Atomic Energy".

Chemical Society (at Burlington House, Piccadilly, London, W.1), at 7.15 p.m.—Scientific Papers.

Friday, March 4

Textile Institute (at 16 St. Mary's Parsonage, Manchester), at 1 p.m.—Mr. T. C. Williams: "Research in the Bedding Industry".

Geologists' Association (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 6 p.m.—Mr. E. Ernest S. Brown: "Work for Amateur Geologists" (Presidential Address).

Institution of Mechanical Engineers (joint meeting with the Institution of Electrical Engineers, at Storey's Gate, St. James's Park, London, S.W.1), at 6 p.m.—Mr. W. F. Harlow: "Causes of Flue-gas Deposits and Corrosion in Modern Boiler Plants".

Royal Statistical Society, London Group of the Industrial Applications Section (joint meeting with the London Section of the Society of Chemical Industry, at the E.L.M.A. Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Mr. G. P. Box: "Statistical Methods in the Interpretation of Experimental Results".

University of London (at the Royal Holloway College, Englefield Green, Surrey), at 8 p.m.—Prof. Paul Dienes: "Science and Ethics".*

Royal Institution (at 21 Albemarle Street, London, W.1), at 9 p.m.—Prof. E. K. Rideal, F.R.S.: "The Foundation of the Royal Institution".

Saturday, March 5

Nutrition Society (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 10.30 a.m.—Conference on "Nutrition and Fertility".

Royal Aeronautical Society (at the Institution of Civil Engineers, Great George Street, London, S.W.1), at 11 a.m.—Discussion on "Air Safety".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Animal Husbandry Adviser at the British Middle East Office in Cairo—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting G.27/49 (March 5).

Demonstrators at the Military College of Science, Shrivenham, near Swindon, in Mathematics (Ref. A.299/48A), Ballistics (Ref. A.299/48A), Physics (Ref. A.299/48A), Chemistry (Ref. F.706/48A), and Metallurgy (Ref. F.707/48A)—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting the appropriate Ref. No. (March 5).

Statistician to maintain statistical sub-offices at Entebbe and Dar-es-Salaam and to carry out surveys on behalf of the East African High Commission—The Director of Recruitment, Colonial Service, Sanctuary Buildings, Great Smith Street, London, S.W.1 (March 5).

Senior Scientific Officers or Scientific Officers, Experimental Officers or Assistant Experimental Officers, for work on safety measures and other research problems connected with the industrial use of explosives and high pressure acetylene, in a Ministry of Supply Research and Development Establishment in London—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.1189/48A (March 10).

Senior Scientific Officers, Scientific Officers, Experimental Officers and Assistant Experimental Officers (unestablished) with practical experience of the working and deformation of metals or of experimental technique in determining alloy constitution, or some knowledge of powder metallurgy, metallography, physics of metals, X-ray crystal analysis or corrosion problems, in Ministry of Supply Research and Development Establishments in London and South England—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.1190/48 (March 10).

Principal Scientific Officers or Senior Scientific Officers, with recognized qualifications in veterinary science with research experience in bacteriology, for unestablished veterinary research posts in a Ministry of Supply Research and Development Establishment in Wilts—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting G.8/49A (March 10).

Scientific Officers with good Honours degree in a biological science or in chemistry, with research experience in biochemistry, physiology, pathology, pharmacology, or bacterial chemistry, and Experimental Officers with a minimum of three years laboratory experience in pathology, bacteriology, biochemistry or physiology, at Ministry of Supply Research and Development Establishments in Wiltshire and Hampshire—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting G.550/48 (March 10).

Chemist or Chemical Engineer for fundamental theoretical and experimental work including work on corrosion, a Chemical Engineer for development of chemical processes subsequent to the laboratory stage and design of plant from pilot plant to larger scale, a Physicist for design, development, manufacture and operation of special instruments for chemical plant, and a Mechanical Engineer for experimental work on problems of stress measurement and high pressure technique, etc., in the Chemical Engineering section of a Ministry of Supply Research and Development Establishment in Essex—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.1188/48A (March 10).

Experimental Embryologist or Immunologist in the Department of Zoology—The Secretary and Registrar, University College of North Wales, Bangor (March 11).

Physicist in charge of a section concerned with the application of radio-active tracer elements—The Registrar, The University, Reading (March 12).

Senior Scientific Officers (with good honours degree in chemistry or physics or equivalent qualification) and Scientific Officers (with good honours degree in chemistry or equivalent qualification), for analytical work in connexion with atomic energy development (Ministry of Supply Chemical Inspectorate)—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.48/49A (March 12).

Lecturers in the Department of Electrical Engineering (Electrotechnics)—The Registrar, The University, Liverpool (March 14).

Readership in Theoretical Physics at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 21).

Professor of Organic Chemistry, and a Professor of Theoretical Physics, in the University of Cape Town—The Secretary, Association of Universities of the British Commonwealth, 32 Woburn Square, London, W.C.1 (March 31).

Chair of Physiology at King's College, Newcastle-upon-Tyne—The Registrar, University Office, 46 North Bailey, Durham (March 31).

I.C.I. Research Fellowships in Chemistry or Physics, or some allied subject such as Biochemistry, Chemotherapy, Pharmacology, Metallurgy or Engineering—The Registrar, The University, Liverpool (April 15).

Ramsay Memorial Fellowships for Chemical Research—The Joint Honorary Secretaries, Ramsay Memorial Fellowships Trust, University College, Gower Street, London, W.C.1 (April 16).

Geologists in the Colonial Geological Survey Service (mainly in the East and West African Dependencies, the Federation of Malaya, and the British Solomon Islands Protectorate)—The Director of Recruitment, Colonial Service, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Industrial Chemist at a Ministry of Supply factory in Nottinghamshire, to be responsible under the Chemist-in-charge for the chemical, metallurgical and testing laboratories and the electro-deposition plant at a heavy engineering factory—The Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting F.65/49A.

Graduate or A.R.I.C. for analytical research for metallurgical problems—The Director, British Cast Iron Research Association, Alvechurch, Birmingham.

Graduate (or equivalent) as Assistant in enquiry laboratory dealing with works problems submitted by member firms—The Printing, Packaging and Allied Trades Research Association, Randall Road, Leatherhead, Surrey.

Physical Chemist (Assistant Scientific Officer or Scientific Officer grade) with an Honours degree in Chemistry, to carry out research on rubber latex and other emulsion systems—The Secretary, Research Association of British Rubber Manufacturers, 105–7 Lansdowne Road, Croydon, Surrey.

Bacteriologist (male) for work in the Stack Laboratories, Khartoum—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Bacteriologist'.

DEVELOPMENT OF BACKWARD TROPICAL REGIONS

IN a memorandum issued with the first report of the Select Committee on Estimates for the session 1948–49*, the Colonial Office replies to some earlier criticisms by the Committee suggesting that there was no coherent strategy of economic planning in the schemes for Colonial development which had been put forward. The Colonial Office in its reply refers to an unpublished memorandum of April 1944 on "The Planning of Social and Economic Development in the Colonial Governments", which states that the two primary objectives of British Colonial policy are the promotion of the best development of the social and political institutions of Colonial peoples, and of their true welfare in the widest sense. The memorandum assumes that the planning of developments to be undertaken in the Colonies would be 'outline' planning in the sense of providing a general framework while leaving a more or less substantial residue of decisions about production and consumption to private planning or individual initiative. On this interpretation of planning, in which strategy is defined as the selection of objectives and the marshalling of the forces necessary to reach those objectives, the Colonial Office submits that there has been a perfectly coherent strategy. The reply goes on to point out that from the beginning it was made clear that the ten-year 'developments' were not to be imposed from Whitehall, but were to be the creation of Colonial Governments and indeed of Colonial peoples themselves. The execution of the plans and the tactics employed are then defended, but in a way which is not altogether convincing.

There is, perhaps, less difference between the Colonial Office and the Select Committee on Estimates than the Colonial Office is disposed to admit. Far more stress was laid by the Select Committee on the necessity of associating the Colonial peoples with development plans at an early stage than would appear from this reply. The Colonial Office indicates the difficulties in co-ordinating the planning of developments in forty-five separate territories; but it never really answers the fundamental criticism that early information on the acute shortages of equipment, materials and man-power, which have brought certain schemes into acute competition for capital equipment required urgently for European reconstruction and development, could only have come from Whitehall. In the field of capital equipment it would seem that a case can be made for criticism. The Select Committee recommended that schemes of Colonial economic development requiring equipment in short supply should be framed in consultation with a planning authority in the United Kingdom having responsibility for allocation among home needs, export demands and all forms of Colonial development. This recommendation the Colonial Office regards as impracticable; but it recognizes the importance of the considerations on which the recommendation is based and is attempting to meet the need in other ways. Other recommendations of the Select Committee, it is stated, have already been adopted.

---

* First Report from the Select Committee on Estimates. Session 1948–49. (London: H.M. Stationery Office, 1948.) 9*d*. net.

Despite this rather heavy-handed reply, it would appear that the criticism of the Select Committee has not been wide of the mark and has had an effect. Moreover, it is obvious from recent discussions on the progress of the groundnut scheme in Tanganyika that the bearing of the general criticism of the Select Committee on the operations of the Overseas Food Corporation has not escaped notice. It has at least strengthened the hands of those who are pressing for information both on the progress of the groundnut scheme and for parliamentary discussion on the activities of the Corporation. President Truman's recent proposal for American participation in the development of backward areas adds a further powerful reason for full public discussion of all the issues involved in Colonial development.

That there is much of scientific interest in such discussion requires no stressing. Thus, Mr. A. J. Wakefield read a paper on the groundnut scheme in East Africa before Section D (Zoology) at the British Association meeting at Brighton in which he emphasized the long-term character of the project and the way in which it is associated with questions of the production of other crops ; he showed that it calls for the services of agronomists, soil chemists and surveyors, entomologists, pathologists, plant breeders, biochemists and others. At the same meeting, Sir Frank Stockdale stressed biological aspects of Colonial development, while the contribution of the scientific worker to human welfare in the Colonial territories was also brought out in the addresses of Lord Rennell of Rodd and of Dr. E. Scott Robertson, as well as in a specific discussion on scientific aspects of Colonial development before Section E (Geography).

Since that meeting, the publication of the four reports prepared for the Tsetse Fly and Trypanosomiasis Committee, reviewed by Sir Philip Manson-Bahr in these columns (*Nature*, January 22, p. 118), have demonstrated the thoroughness with which the task of survey and control of trypanosomiasis in Central Africa is being carried out and its bearing on Colonial development as well as health and welfare. The announcement of the new drug 'Antrycide' indicates the way in which scientific and industrial research in Britain is continually providing the medical and veterinary worker, the protozoologist and entomologist with new weapons, and opening up fresh prospects of controlling the major diseases and pests that ravage human and animal life and limit development in tropical areas. Some of these possibilities have no doubt been considered by the International Scientific Committee for Trypanosomiasis Research which met in London on February 8. This non-government standing committee of scientific men from the United Kingdom and the Colonies, France, Belgium, Portugal, South Africa, Southern Rhodesia and the Sudan, was formed as a result of the international conference held at Brazzaville in French Equatorial Africa in February 1948.

An important section of the report of the Commission of Enquiry into the Swollen Shoot Disease of Cacao in the Gold Coast not only praised the work of the West Africa Cacao Research Institute as basic to the maintenance of the cocoa industry in the Gold Coast, but also suggested an extension of research involving a considerable increase in both the facilities and staff at the Institute. It will also be recalled that in launching the groundnut scheme, the Government expressed the belief that its long-term importance might lie less in increasing the supply of fats for Britain and the rest of Europe than in its practical demonstration of the improved productivity, health, social welfare and prosperity which scientific agriculture can bring to Africa. In a recent address to the Manchester Statistical Society, urging the need for more capital for the Colonies, Prof. Arthur Lewis emphasized that more than this is required. The fundamental needs in all colonies are, in fact, the same. Apart from greater capital investment, the people must learn the laws of good husbandry. Proper cultivation, protection against erosion, the planting and felling of trees, selective breeding of livestock and irrigation where possible are fundamental in the development of every Colony. Behind all lies the need for further research in tropical agriculture: research into plant diseases and fertilizers, the breeding of immune varieties, methods of conserving water, the elimination of pests and the preservation of animal health.

The demands that are thus made on the Colonial Powers may well absorb all the surplus resources of Western Europe for years to come, and indeed a large part of those of the rest of the industrial countries of the world. This demonstrates the immediate significance of President Truman's proposal. This proposal would appear to accept and endorse the recognized basis of British Colonial policy, namely, that the development of the backward areas can only be achieved with outside technical and scientific assistance and large capital investment which must be carefully watched and controlled to avoid exploitation ; and it offers to put the vast resources of the United States behind a great effort to carry out such a policy throughout all the under-developed areas of the world. Such association in itself may well prevent misunderstandings, which may sometimes arise when economic development appears to clash with the advance towards full self-government, and so forestall misrepresentation. The announcement that the Economic Co-operation Administration has approved the British Government's proposal for the augmentation of the Colonial Surveys by about fifty trained American workers, whose salaries would be met by that Administration, is a welcome sign of the beginning of such co-operation.

Research and education must, indeed, precede capital development, and it is a task which Great Britain at present finds peculiarly difficult, owing to its straitened resources of scientific man-power, to discharge adequately even within the Colonial Empire. It may well be hoped, therefore, that one effect of Mr. Truman's proposal may be so to implement both the Fulbright Act, which provides for sending

Americans to study, teach and engage in research abroad and for the cost of travel of nationals of other countries who wish to visit the United States for similar reasons, and also the Smith - Mundt Act of January 1948 for the establishment of an educational exchange service. An agreement between the Governments of the United Kingdom and the United States to put the Fulbright Act into effect was signed on September 22, 1948, but in the present currency situation the chief beneficiaries will be Americans. If, in view of the President's proposal, Congress now makes the necessary appropriations under the Smith - Mundt Act for international co-operation in the interchange of persons, knowledge and skills, the rendering of technical and other services and the interchange of developments in the field of education, the arts and the sciences, the purpose of the Fulbright Act may still be achieved.

Meanwhile, it is worth noting that the Colonial Office has now begun to issue a *Journal of African Administration*, one of the aims of which is to serve as a link between research and administration; the first issue refers to contacts which are being developed between the Colonial Office and the appropriate departments and institutions of foreign Colonial Powers. Here is further encouragement for men of science working in fields touching on human welfare, health and agricultural development, who have already recognized how much international co-operation can do to make their efforts fully effective in areas such as tropical Africa. President Truman's proposal is rightly linked with the European recovery programme and the firm establishment of world order; but there are few fields in which Anglo-American co-operation, the pooling of knowledge and scientific and technical resources and the interchange of staff, could contribute more quickly and richly to human welfare and social advance throughout the world than in the development and education of the backward areas of the world.

TAXONOMY OF THE HAWKWEEDS

A Prodromus of the British *Hieracia*

By H. W. Pugsley. (Journal of the Linnean Society of London, Botany, Vol. 54.) Pp. iv+356+17 plates. (London: Linnean Society, 1948.) 60*s*.

THE hawkweeds have long been known as a group of plants presenting peculiar difficulties to taxonomists. The general facts can be simply stated: in most parts of the generic range the hawkweeds are more or less locally limited entities which morphologically differ definitely, but not greatly, from other entities. These microspecies, or whatever they be called, come true in their differential characters from seed. In the British Isles, the northern and western parts are richest in *Hieracia*, and in the past their study has attracted many British botanists. The late Mr. H. W. Pugsley published "Notes on British Hawkweeds" in 1920, so that it is safe to say that the present prodromus is the result of more than a quarter of a century's investigations.

Within the limits of a 'micro-taxonomical' subject the work is in many ways excellently done. The descriptions are clear, sufficiently full yet concise, and easily comparable one with another. There is judicious citation of specimens and localities. The history of the classification of British *Hieracia* is adequately considered, and there is an interesting section on their morphology.

A conspectus of accepted species classifies these into sections and series; but it is unfortunate that no artificial key is provided to the latter. The greater part of the prodromus consists of descriptions with keys to the 260 groups recognized as species, the keys being generally placed under the series into which the species are classified. A considerable number of such species are here described and named for the first time. Under some of the species varieties are accepted. There is an index to the species and subsidiary groups, and seventeen plates show plants in black-and-white outline.

Various questions arise in perusing this volume. Modern research has shown that many *Hieracia* are apomictic—they set seeds without fertilization. Much of this cytological research has been done in Scandinavia, and apparently British hawkweeds have not been examined for their chromosomes or the absence of fertilization. There is, however, very little doubt that the entities accepted by Pugsley as species are apomicts (or groups of apomicts). Genetically, apomicts are the equivalent of clones. Unlike clones that are propagated, as clones, only by vegetative means, they spread by seeds which reproduce the clone. With these peculiarities there are good arguments for maintaining that apomicts should be taxonomically treated neither as species nor as varieties, but should be classified as distinct categories. It is to be regretted that Mr. Pugsley did not explain clearly the general principles by which he determined which of the presumably apomictic entities should be considered 'species' and which 'varieties'.

Another matter that may be disputed is his treatment of the part played, in the more or less long distant past, by hybridization. On this matter his statements appear to be confused. If *Hieracia* be completely apomictic, at the present day, hybridization cannot occur between the apomicts; but this does not mean that hybridization did not occur when amphimixis was the rule in the genus. Indeed, some cytologists have held strongly that hybridization is an important cause of apomixis.

W. B. TURRILL

THE SPECIES OF MODERN MAN

Human Ancestry from a Genetical Point of View

By Professor R. Ruggles Gates. Pp. xvi+422+27 plates. (Cambridge, Mass.: Harvard University Press; London: Oxford University Press, 1948.) 42*s*. net.

THE subdivision of modern man into distinct species rather than into "races" is justified in the first instance, says Prof. R. Ruggles Gates in his new book, on the score of "convenience" (p. 11). "Consistency in nomenclature and methods of classification necessitate the recognition of several species of living man", he adds (p. 406). Like Prof. Ruggles Gates, anthropologists well appreciate the difficulty of distinguishing (except arbitrarily) clear-races of mankind and of specifying the criteria by which they are to be recognized. Indeed, at the recent International Anthropological Congress at Brussels the complexity of the problem received fresh affirmation. One might have hoped then that the first-fruits of Ruggles Gates' advocacy of the "convenience and cogency" of human species would be that the latter would prove easier to detect than the conventionally recognized 'races' or variants. However, he does not appear ready yet to adjudicate on the taxonomic rank of the many more or less distinctive groups which he recognizes. (The elaboration and adornment of the charts on p. 56 and p. 161 illustrating these groups need not be taken too seriously.) Towards the end of the book (p. 388) he puts forward five strong claimants to the rank of species in the Caucasian, Mongolian, Australian, Negroid and Bushman stocks; but he does not, unfortunately, justify this selection by any detailed reference to the taxonomic and phylogenetic criteria which he insists are at hand to establish species differences; nor is it made plain in which way these particular 'species' exemplify "consistency in nomenclature and methods of classification". Indeed, it comes rather as an anticlimax to find, near the end of the work (p. 378), that for the conferment of species rank one may have, after all, to fall back on the "opinions of a competent systematist".

Ruggles Gates makes his claim on the score not merely of "convenience"; much of the book is devoted to arguments based on palæontological data. According to him modern man may be grouped in distinct species because the taxonomic differences represent the end-products of evolution along largely isolated lines of development. Continental separation has given rise to the four or five groups which he would regard as distinct species. They have, according to him, been developed from quite separate ancestral stocks of the morphological levels typified by *Pithecanthropus* and *Javanthropus* in the Australian region, *Sinanthropus* in the Far East, Neanderthal man in Europe, and *Africanthropus* and Rhodesian man in Africa. It will be recalled that Weidenreich[1] was the foremost advocate of the view that *Homo sapiens* (the Neanthropic level) had emerged from the more primitive Neanderthal (or Palæanthropic level), and that the latter in turn had its origin in the *Pithecanthropus–Sinanthropus* (or Archæanthropic level). Another view, that of Sergi[2], Le Gros Clark[3], and others, is inclined to the belief that Neanderthal man and *Homo sapiens* represent divergent branches from a geologically earlier group combining features of both, as exemplified in the remains from Steinheim, Saccopastore, Krapina, Mt. Carmel, and elsewhere. There is some uncertainty as to the relationship of this group to the Archæanthropic level.

The emergence of modern man is thus capable of various interpretations, even if it is assumed that the transformation and dispersal at each level have taken place at a single centre. Ruggles Gates finds it easier to believe that this transformation has taken place independently, and presumably at different times, in four or five centres, and that the descendants of these rather dissimilar ancestors have undergone an extraordinary degree of parallelism in their different lineages, yet not enough to obscure their specific differences. It would seem, however, that Ruggles Gates has allowed himself much elasticity in his usage of the concept of 'parallelism'. As applied to man, his usage does not, in spite of his implied claim (p. 39), conform to that of Le Gros Clark. In the latter's interpretation (which is the one generally understood) parallel variations are essentially secondary and often superficial, and this is true, in fact, of many of the accepted cases of parallelism in other animal groups instanced by Ruggles Gates himself. If palæontologists of the standing of Broom and Le Gros Clark do not attribute the humanoid resemblances between *Australopithecus* and *Homo* to merely parallel variations, to describe the similarities among modern men as 'parallelisms' seems completely inconsistent.

Quite apart from the difficulties in Ruggles Gates's phylogenetic interpretations, the arguments based on palæontological data (an impressive compilation in this book) prompt serious misgivings. The author gives credence to many expressions of palæontological opinion which are far from commanding general acceptance. Evidence based on remains such as those of *Eoanthropus*, *Meganthropus*, Kanam man and *Africanthropus*, to mention a few, cannot at the present time, in fact, be used as a basis for any far-reaching generalizations. The material is morphologically and geologically too uncertain. Even where there are well-preserved remains, much caution is needed in accepting the speculations of palæontologists on the affinities of particular fossils. One may take an instance on which Prof. Ruggles Gates places great emphasis—the relationships of the Rhodesian skull. The affinities of this specimen to modern and to Boskop man, to the Bushman, to ancestral Negroes, or Neanderthal man have been interpreted so variously as to yield a remarkable criss-cross of contradictory hypotheses. These probably cancel one another out, as a recent critical article by Dr. L. H. Wells[4] would suggest. In handling the palæontological data, opposing points of view have not, in the reviewer's opinion, been given sufficient critical consideration by Prof. Ruggles Gates. This is the work's most obvious inadequacy, and one which goes far to weaken the thesis the author is so intent to sustain.

SYLVICULTURAL STATISTICS

The Silviculture Research Code

Vol. 2: The Statistical Manual (Being the Application of Statistical Methods to Silvicultural Research in India). By A. L. Griffith and Bakshi Sant Ram. Pp. viii+214. (Dehra Dun: Forest Research Institute, 1947.) Rs. 11.2; 17*s*. 6*d*.

WORKERS in the biological sciences need statistical methods as a tool in the ascertainment of results to be derived from experimentation; in particular, when experiments are of the field order, modern applications to the design and analysis of experiments, mainly the work of R. A. Fisher, are essential. The question then arises whether certain standard texts are sufficient, or whether there is need for a book dealing with methods particular to the special field. The "Silviculture Research Manual" of 1931 is out of date, and it has been decided to publish a new "Code" in three volumes. The opportunity has been taken to expand the treatment of statistics from a single chapter, by H. G. Champion, in the former manual to an entire volume which, although vol. 2 of the "Code", is the first to be published.

It is undoubtedly a convenience for sylviculturists to have their own all-embracing text, although as a matter of fact the only feature of the work under review that is peculiar to sylviculture lies in the numerical data, and the actual experiments chosen for purposes of illustration. Generally, the volume is an expository presentation of those parts of the theory and application of statistical methods that are needed in the domain of field experimentation. Full acknowledgment is made of the sources of the compilation, and, although the authors are evidently not mathematical statisticians, the selection of the material and the general presentation are on the whole sound, while a welcome feature is the considerable detail given to all the calculations; so much so, indeed, that the impression may have been left that computation is more complex than it really is, and the so-called 'short methods' not very short after all.

Part 1—general principles—covers the standard methods needed for estimation and tests of significance up to analysis of covariance, with an added chapter (the longest in the book) on the fitting of simple curves, which is mathematical rather than statistical, and which could with advantage have been integrated with the general study of regression. Part 2 deals with the design of field experiments, describing the ordinary arrangements up to simple factorial designs, including split plots, and giving consideration to experiments repeated in space and time. With some unnecessary repetition from Part 2, Part 3 rounds off the work with nine full-scale examples. It would have been a convenience to readers to point out that variance-ratio tables are available, with all the other tables required, in a single book, "Statistical Tables", by Fisher and Yates.

The main points of criticism are a need in some places for integration of alternative methods, a faulty comparison of a total and partial correlation coefficient on p. 57, and some confusion regarding the use of interactions in space-time experiments (for example, p. 177). But, in any event, sylviculturists will be safer with this book than with some of those given in the list of references, and the authors are to be commended for a useful compilation which will have a general value outside the forestry service.

J. Wishart

SURVEY OF THE GREAT WORLD RELIGIONS

Ethics of the Great Religions

With some Account of their Origins, Scriptures and Practices. By E. Royston Pike. Pp. viii+247+20 plates. (London: Watts and Co., 1948.) 15*s.* net.

THIS is an attractively illustrated and very readable book, but one which nevertheless cannot be altogether recommended as a reliable introduction to the subject. Any attempt to study the great world religions which treats them as, in essence, no more than a number of ethical systems, converging towards something like agreement, inevitably fails to do justice to the specific *differentia* of each particular religion.

A religion is more fundamentally a metaphysical than a moral system. Its ethical commandments and prohibitions are understood and justified by its votaries in terms of its metaphysic, and not the other way round. Religious morality is always a relative morality of adaptation to presumed circumstances, and never an absolute morality justifying itself in terms of belief in a conscience or capacity for moral intuition which functions independently of all metaphysical beliefs and presuppositions. Thus even when the ethical prescriptions of two different religions appear, when abstracted from their respective metaphysical contexts, to be in fundamental agreement, the appearance is, in fact, a misleading one. For example, one religion may cultivate asceticism because it distrusts personal life and selfhood, and wishes men to lull themselves into self-forgetfulness and resignation by the elimination of desire; whereas another may resort to ascetic disciplines for precisely the opposite reason, because it believes in personal existence and seeks to intensify its powers by discipline and concentration. The resemblance, in such a case, will be accidental and superficial; the differences are essential and profound.

The truth is that comparative religion is a subject most appropriately studied, because most sympathetically and with most insight, by a man of personal religious experience and conviction. To write about the observed phenomena of religion without knowing the inward discipline of 'being religious' is rather like trying to contribute to the progress of physical science without acquainting oneself with the laboratory techniques of controlled observation and experiment which it employs. It may be replied that the teacher who is a disciple of no one of the great world religions is more likely to display impartiality as between them all than, shall we say, a Christian teacher. But this is one of the great errors of so much liberal educational thought. The real virtue of the teacher is not impartiality—a quality which the mere dilettante can simulate easily enough—but justice, the stern intellectual self-discipline which enables a man who has committed himself utterly to the guidance and promptings of his own convictions to look with charity and understanding upon those of others. Thus a book like this fails to satisfy the Christian reader; but it fails equally, and for the same reasons, to satisfy the Moslem or the Buddhist. A Christian writer on the same subject would do justice to the specific *differentia* of Christianity; but at the same time, and as part of the same process, he would also render a similar service to Islam and Buddhism, and leave the Moslem and the Buddhist at all events less dissatisfied.

To the Christian the author's treatment of Christianity seems particularly defective—he shows, for example, no knowledge or even suspicion of the tendency and implications of recent discoveries in the realm of biblical criticism (he is "almost certain" that St. John's Gospel was not written "earlier than 100 A.D.")—but no doubt a Buddhist would feel that his account of Buddhism is his greatest failure, while a Moslem would complain in particular of a pathetic inability to penetrate the secret of the power of Islam. To be equally unjust to everybody is indeed a travesty of real impartiality; but it is often the fate of the secularly minded doctrinaire liberalism which, in the modern world, has brought the genuine liberal values of our culture into their present parlous condition.

J. V. Langmead Casserley

The Penrose Annual

A Review of the Graphic Arts. Edited by R. B. Fishenden. Vol. 43. Pp. xii+140+40+139 plates. (London: Percy Lund, Humphries and Co., Ltd., 1949.) 21*s.* net.

"THE Penrose Annual" is an old friend of all connected with the printing industry, and its return after an absence of nine years is very welcome. This, the forty-third volume, follows the well-established lines of its predecessors, which in some ways is a pity, because in the nine years elapsing between the appearance of Volume 42 and Volume 43 the printing industry has had experiences which should be recorded. And where more appropriately than in "Penrose's"? The record is desirable not only for historical reasons, but also because much valuable experience was gained in solving problems which arise in an industry in total war, and this should not be lost.

The Annual consists of its usual four parts—"General Articles", "Technical Articles", specimens of contemporary printing and advertisements; and each contributes to the usefulness and interest of the book as "A Review of the Graphic Arts", a usefulness which does not diminish as the years pass. The "General Articles" are concerned mainly with typography and design, illuminated by the outstanding contribution of H. J. Deverson, "Photography in Battledress". The "Technical Articles" cover a wide field, and give promise that there may be outstanding technical developments in the printing industry before long. The printing specimens, covering all the major processes, are excellent in quality and show that British printing is second to none. Anyone who has an interest in good printing and in the ways in which it is produced will find much enjoyment in this volume—now and in twenty years time. It is excellent value for a guinea.

If old friendship permits of frankness, it is to be hoped that one or two of the authors, before they make their contributions for Volume 44, will take a little time off from printing to read Sir Ernest Gower's "Plain Words". There is at least one paragraph in Volume 43 which is good enough for *Punch.*

Proceedings of the Aristotelian Society

New Series, Vol. 47: Containing the Papers read before the Society during the Sixty-eighth Session, 1946–1947. Pp. xx+300. (London: Harrison and Sons, Ltd., 1947.) 30*s.* net.

IT is not infrequently asserted that we are unable, these days, to 'afford' pure knowledge, that it is an intellectual luxury, that it should be strictly rationed, and so forth. Luckily, in addition to *ad hoc* protests against a view so shocking, there occur certain periodic implied reactions; the appearance of a new volume of the *Proceedings of the Aristotelian Society* is one of these, and deserves a special welcome.

There is little continuity to be discerned in this collection; indeed, it is scarcely to be expected; the value lies in its 'forge-like' character, wherein thought-stuff is hammered out, fashioned, tempered and annealed. For example, the president's address provides some teleological clothing for E. S. Russell's functional biology; another contributor presents an exceptionally sensitive view of the role of pain in creative activity, while further on we meet with a penetrating analysis of existentialism in terms (largely) of its historical background. Kierkegaard, typical of a 'crisis-philosopher', fastened upon the story of the immolation of Isaac a nineteenth-century reflexion of the extreme credal position assumed ages before by Tertullian. The last paper is a most interesting exposition of the tentative method of approach to logical definition. Thus, in these ways, and in many more, we are refreshed and stimulated; but above all, it is good to know that some people still ponder for pondering's sake, and for no other reason.

F. I. G. RAWLINS

The Making of Scientific Management

By L. Urwick and E. F. L. Brech. Vol. 3: The Hawthorne Investigations. Pp. x+225+8 plates. (London: Management Publications Trust, 1948.) 12*s.* 6*d.* net.

THE findings and interpretation of what are known as the Hawthorne Investigations, carried out in the United States for the Western Electric Co. at its Hawthorne Plant, are of great interest to all concerned with problems of industrial relations and productivity in Great Britain, where the human factor is frequently the decisive one with which management has to deal. These findings, however, have been presented in seven main publications, four of which deal directly with the research activities and their results, while the other three use certain aspects of those findings to illustrate wider industrial and sociological problems of our time, such as that of leadership in a free society. This volume draws freely on those sources, giving a connected critical account which should be welcomed by those to whom the original volumes (some of which are out of print) are inaccessible. It will give most managers a sufficiently detailed account of the investigations, even if perforce some of the stimulus and vitality of Elton Mayo's and T. N. Whitehead's original books are lacking; and the brief notes on the original volumes which are included will direct those who wish to study the findings in more detail to the appropriate source.

R. B.

Report on Fungus, Bacterial and other Diseases of Crops in England and Wales for the Years 1943–1946

By W. C. Moore. (Ministry of Agriculture and Fisheries, Bulletin No. 139.) Pp. vi+90+12 plates. (London: H.M. Stationery Office, 1948.) 2*s.* 6*d.* net.

THE number of plant diseases, or at least the measure of man's awareness of them, is constantly increasing. Mr. W. C. Moore records twenty-six new diseases and twenty-one new host records during the four years 1943–46. It is possible, however, that only one of these new enemies—bacterial canker of tomato—is likely to add a serious challenge to plant pathologists. The disease, caused by the organism *Corynebacterium michiganense*, has appeared on outdoor tomatoes, mostly in the south-east of England, where some of the outbreaks have involved the death of considerable numbers of plants. The bulletin, however, does more than record the appearance of new diseases; it also assesses the status of pathogens which are recognized already. There is a growing tendency for advisory plant pathologists to become more truly quantitative in their estimates of disease, and Mr. Moore draws freely from the reports of his advisory colleagues and other collaborators. Graphs show the comparative phenology of potato blight in Cornwall, Devon and Yorkshire. Maps show the present position of diseases which are extending geographically, such as red core of strawberries, bacterial canker of tomatoes, asparagus rust, onion smut, and grey bulb rot of tulip. The results of surveys of take-all of wheat, yellows of sugar beet, wart disease of potatoes, and *Didymella* stem-rot of tomato are also given.

It is not the function of this publication to give lengthy descriptions of plant pathogens ; but the text nevertheless includes useful notes on some of the more uncommon troubles. Citations of recent and relevant literature are very frequent, and several photographs of particular diseases are reproduced. The whole makes a very modern symposium of plant pathology in England and Wales, showing the success of control measures for some diseases, indicating the need for new methods of prevention or eradication for others ; it holds the balance between those troubles which are only of scientific interest and those which provide a serious incubus on crop production.

J. G.

Diseases of Cereals

By Dr. W. A. R. Dillon Weston. Pp. x+69. (London, New York and Toronto : Longmans, Green and Co., Ltd., 1948.) 4*s*. net.

HOW cereal diseases can be recognized and controlled is shown in the twenty-six pages of this well-produced and generously illustrated book. The author, as advisory plant pathologist, has devised life-cycles, attractively illustrated by Miss Ann Murray, to demonstrate diagrammatically important stages in the lives of organisms causing cereal diseases, and the means by which they can be controlled. These are used with other drawings to illustrate accounts of diseases caused by fungi and other ailments of cereals. The improvement in crop health since seed disinfection became general is indicated.

This book will be particularly useful to farmers and students for whom it is primarily designed ; and practising plant pathologists will appreciate the clear and concise accounts showing how modern knowledge is used in controlling disease. M. D. G.

Five-Figure Tables of Natural Trigonometrical Functions

Prepared by H.M. Nautical Almanac Office. Pp. iv + 124. (London : H.M. Stationery Office, 1947.) 15*s*. net.

THESE tables were originally prepared in 1941 by the Nautical Almanac Office, at the request of the War Office, for use in survey calculations. In 1945 they were reprinted, but the present issue, dated 1947, is the first one to become available to the general public. They contain *natural* values only, and are intended to replace similar tables, published in 1924 (in Part 2 of the "Manual of Artillery Survey"), which provided *logarithmic* values of the same four functions. It should be emphasized that they are primarily designed for use with calculating machines and are of no great practical value unless such a machine is available.

There are two distinct sections, in the first of which, the auxiliary section occupying some thirty pages, values of the cotangent are given to five significant figures for every second of arc up to 7° 30′. The main table, comprising ninety pages, contains values of the sine, tangent, cotangent and cosine arranged semi-quadrantally for every ten seconds of arc. In the cotangent tables for the range 27–45°, six significant figures are available, there being five only for the remaining entries. Information supplied at the heading of each third of a page enables the range of the tables to be extended to 360° without difficulty, and as the tabular intervals are so small no differences are provided, as interpolation is not considered necessary.

A short list of minor corrections which have been incorporated since 1945 and another of errata noted after printing are appended ; the book is well bound and clearly printed. J. H. PEARCE

Reports of the Progress of Applied Chemistry

Vol. 31, 1946. Pp. 745. (London : Society of Chemical Industry, n.d.) n.p.

IT is unfortunate that, owing to circumstances over which the editors no doubt have no control, the "Annual Reports" for 1946 have appeared only in 1948. Taking into account the fact that the publication of a paper may involve a year's delay, most of the actual work described is from three to four years old.

Apart from this defect, the volume maintains the usual excellence of the series. It is divided into twenty-eight main sections, to which forty-seven well-known authors have contributed. In general, these sections follow the headings adopted by *Chemical Abstracts*. One interesting departure is noted: "Pest Control" is given a separate section of 19 pages with 173 references, thus showing the growing importance of the subject. The main sections are subdivided, making it easy for a reader to look up any subject in which he may be particularly interested. The references cover an extremely wide range, and include papers or patents which may easily be overlooked without such guidance.

The subject-matter, varying from the production of ammonium sulphate in Turkey to the solubility of carbon in molten copper and the disposal of kitchen waste, is too varied to enable even an indication of its nature to be given ; but it may confidently be stated that few readers can glance through this volume without catching sight of something of unusual interest. H. E. WATSON

Sequence in Layered Rocks

A Study of Features and Structures useful for Determining Top and Bottom or Order of Succession in Bedded and Tabular Rock Bodies. By Prof. Robert R. Shrock. Pp. xiii+507. (New York and London : McGraw-Hill Book Co., Inc., 1948.) 45*s*.

THE use of features such as graded bedding and cross-lamination, pillow lavas and pipe amygdales, to establish the order of succession in a series of folded strata is but briefly dealt with in text-books of geology. Prof. Robert R. Shrock sets out to describe and illustrate not only these better-known top and bottom criteria, but also all other features, structures and relations which have been or might be employed in determining the original order of succession in sedimentary, igneous and metamorphic rocks. His comprehensive compilation is a work of quite a new kind which can be used with advantage to supplement existing texts of a more general nature. While prepared specifically for students, it will form a valuable review for experienced field geologists, who will undoubtedly find it most stimulating. The illustrations comprise some 500 line drawings and more than 150 photographs, nearly all of which are new to text-book literature. A bibliography of seven hundred items is drawn principally from American and British publications.

COUNT RUMFORD AND THE FOUNDING OF THE ROYAL INSTITUTION

By THOMAS MARTIN
General Secretary, Royal Institution

A HUNDRED and fifty years ago, on March 7, 1799, a meeting was held at the house of Sir Joseph Banks in Soho Square, London, to consider proposals for founding a new scientific institution in London. The gathering in Sir Joseph's principal room or council chamber included a number of peers, members of Parliament and public men, with others distinguished for their scientific attainments or well known for their charitable and philanthropic activities. Those who had been called to the meeting were the contributors of fifty guineas each in response to an appeal "for forming by subscription, in the Metropolis of the British Empire, a Public Institution for diffusing the knowledge and facilitating the general introduction of useful mechanical inventions and improvements, and for teaching by courses of philosophical lectures and experiments the application of science to the common purposes of life".

The founders of the new institution had gone far towards ensuring the success of their enterprise by enlisting the help of Sir Joseph Banks, the all-powerful president of the Royal Society. Such was his influence in all scientific matters at this time that it is doubtful if they could have succeeded had he opposed their plan. As it was, he presided at the meeting, the proposals, which had been printed and circulated, were adopted, and it was resolved to petition His Majesty King George III for a royal charter. A committee of managers was appointed and requested "to take preparatory measures for opening the Institution". Thus by resolution of this original body of proprietors, the Royal Institution of Great Britain, as it was afterwards named in the charter, came into existence.

Sir Joseph presided at the early meetings of the managers, which were held almost weekly at this time, and the Royal Institution owes much to his sponsorship and encouragement; but for the true inspirers and originators of the project we must look in a less obvious, and somewhat unexpected, direction. Among the subscribers who attended the original meeting were William Wilberforce, Thomas Bernard and Count Rumford. Wilberforce, the member of Parliament for Yorkshire, was the great advocate of the abolition of slavery. Thomas (afterwards Sir Thomas) Bernard was the treasurer of the Foundling Hospital. Sir Benjamin Thompson, Count Rumford, was that remarkable soldier, statesman and man of science who had been born in America and had come to England during the War of Independence: he had recently returned to this country after a long period in high office under the Elector Palatine of Bavaria. Only one of these three, Rumford, had scientific attainments to account for his interest in the new institution; but all were actively engaged in humanitarian and philanthropic enterprises, and in particular were associated in the affairs of a society called the Society for Bettering the Condition and Increasing the Comforts of the Poor.

Rumford, whose title as a Count of the Holy Roman Empire had been conferred on him by the Elector Karl Theodor, had spent the most active and fruitful years of his career in Bavaria. It was in Munich that the greater part of his scientific work on heat had been carried out, including his well-known experiment on the source of the heat excited in the boring of cannon at the Arsenal; but his experiments were by way of relaxation, in a life fully occupied with military and administrative duties. In these he had shown great enterprise and versatility, providing the firm hand which was sorely needed by the Elector in the government of his country. Bavaria was suffering from the ravages of war, there was corruption in high places and poverty and lawlessness among the people. Gangs of beggars and vagabonds, many of them ex-soldiers, roamed the country, converging on Munich, where they systematically extorted alms from the more law-abiding citizens.

The state of affairs had become intolerable, and after much consideration Rumford devised a plan, which with the aid of the military he put into operation on New Year's Day, 1790, for arresting all the beggars in the city. The able-bodied were put to useful work in 'houses of industry' and the infirm given alms from funds subscribed by the citizens. Thereafter begging was prohibited. By his humane and enlightened methods with the poor people and his care in the administration of his 'institutions for the poor', Rumford succeeded in making his system work and in ridding Munich of its incubus for a considerable period of years.

He became much interested in the problems of practical philanthropy, and devoted attention to such matters as economy of fuel, the design of stoves and fireplaces, the improvement of cooking utensils and the preparation of nourishing food at a minimum of cost. The fame of his methods spread to other countries, and he was consulted everywhere on the economy of establishments for the poor. 'Rumford soup kitchens' and 'eating houses' were set up in many places. In London he advised on the arrangements at the Foundling Hospital. Its treasurer, Thomas Bernard, was a particular admirer of his methods, and in 1796 proposed the formation of a society to promote their introduction into Britain. The society thus established, with the active co-operation of Wilberforce and other philanthropists, was the 'Bettering' Society mentioned above.

It was naturally with his friends in the Bettering Society that Rumford discussed a particularly cherished scheme, that of an institution to be devoted to the application of science and invention to the improvement of the lot of the poorer classes; and early in 1799 the Society launched the appeal which, as we have seen, resulted in the formation of the Royal Institution. The Bettering Society was thus the precursor of the Institution; but Rumford early decided that this new establishment was too interesting and important to be merely an appendage of another society. In the proposals, therefore, which he drew up himself, and in which its objects were described in great detail, it was given a separate constitution; and as he worked on the scheme its magnitude and its possibilities grew in his eyes. Before long the house in Albemarle Street, which the Institution still occupies, was purchased; and the royal charter was duly granted by the King. At the request of the managers, Rumford went to live at the house, so that he could personally supervise every detail of the arrangements, and for two years this became his principal occupation.

A special feature of the Institution was to be the Repository or Model-room in which working models of new inventions were to be exhibited. There were to be fireplaces, stoves and kitchen utensils of the latest design. A complete kitchen was to be equipped, from which meals would be served to the proprietors. Workshops would be established and classes held for the instruction of artisans and mechanics. The speedy introduction of all useful mechanical inventions and improvements was to be one of the two principal objects; the other was the application of science to the improvement of arts and manufactures, and for this purpose a lecture room and laboratories would be provided, professors and lecturers engaged, courses of philosophical lectures would be given and chemical and other experiments carried out. For the management of the Institution there were to be committees of managers to govern and direct, and 'visitors' to inspect and audit, responsible to the proprietors, whose interest was hereditary.

For a time the efforts of the early managers met with much success. The ninth Earl of Winchilsea became the first president; the nobility and gentry, the philanthropic and the learned, gave their support as proprietors or subscribers. The lecture theatre, now famous as one of the best for its purpose in existence, was built, the model room, laboratories and workshops constructed and equipped, and the library and reading-rooms opened to the proprietors. Dr. Thomas Garnett, from Anderson's Institution in Glasgow, was engaged as the first professor, and courses of lectures were begun.

This was the Royal Institution as it was originally conceived, and although there have been great changes, those who know it will recognize much that has survived to the present day. It was Rumford's plan, and in the early years his ideas were closely followed. He is rightly regarded as the founder; although by some a share at least of the honours has been claimed for Sir Thomas Bernard.

After a time, however, differences of opinion arose. Rumford quarrelled with Prof. Garnett, and he fell out with some of the other managers, who found him dictatorial and overbearing. Not all of them were in sympathy with his philanthropic ideas or believed that the poor and the working classes in Britain would respond to the methods he had found successful in Bavaria. Moreover, the plan for the Institution proved too ambitious and expensive and had to be curtailed. Rumford began to lose interest; he went off to the Continent again, intending to return; but, in fact, he stayed in Paris to marry the widow of the great French chemist Lavoisier.

The control of the Royal Institution fell into other hands. The new managers quietly dropped the classes for mechanics, the cooking and kitchen economy, and other features of Rumford's plan, and endeavoured to popularize the establishment with those to whom it looked for financial support by arranging courses of lectures on popular science, literature and the arts. Sir Joseph Banks in London grumbled by letter to Rumford regretting his absence, telling him that the Institution was "now entirely in the hands of the profane" and declaring that he would have nothing more to do with it.

But the changes which now took place were due not so much to acts of the management as to the activities and growing reputation of Humphry Davy. Before he left England, Rumford had engaged this young man from Bristol as lecturer in chemistry. Thomas Young had succeeded Garnett, and for a time Young and Davy worked together. Later, Davy became the professor of chemistry, and it is well known how his gifts as a lecturer and his brilliant researches on the chemical action of electricity established both his own reputation and that of the Institution. Scientific research and exposition became the order of the day.

This alteration of purpose was frankly recognized by an Act of Parliament in 1810, which amended the constitution of the Institution, extending its objects to include the "promotion of chemical science by experiments and lectures" and the "diffusion and extension of useful knowledge in general", and substituting for the hereditary proprietors, who were compensated and dispossessed, a body of elected members. Constitutionally, the Royal Institution as we know it to-day dates from the Act of 1810; but its character and traditions were established by the brilliance of Humphry Davy, to be maintained and enlarged by the genius of his assistant and successor, Michael Faraday.

At this hundred and fiftieth anniversary, however, we celebrate the founder, Benjamin Thompson, Count Rumford. He made probably his greatest contribution to its success when he brought Humphry Davy to work in his Institution; and if it is something of a changeling from the establishment he originally intended, none will now deny him credit for the importance of his achievement or its significance in the history of science.

FOREST RESOURCES OF THE WORLD

A SMALL booklet has recently been issued by the Food and Agriculture Organisation of the United Nations, Division of Forestry, entitled "Forest Resources of the World" (Washington, D.C., 1948). This report is of first importance and interest, and discloses the steps which have been taken to have a real inventory of the world's forestry resources prepared, a piece of work far more difficult of achievement than might be supposed. This difficulty is due to the fact that a considerable proportion of the forests of the world are still without any really proper and efficient management. Consequently, any figures obtained on the subject of the abundance or otherwise of their several resources can, in certain cases, be accepted only with reserve.

The report commences with the question as to whether or not man will be compelled to resign himself to a perpetual shortage of forestry products. To this the report's answer is 'No', and this reply applies to a still larger population than at present exists. It will be of interest to follow the argument which, of necessity, must be based to a considerable extent on the still untapped forests of the world.

From earliest times a large section of the world's population has depended on the forest—at first for fuel only, then for timber for house construction, farm implements and so forth. The introduction of more modern forms of building, it was said, would see the importance of timber decrease and, therefore, the people's corresponding dependence on the forest. The reverse has been the case. The modern industrial age has brought with it new demands on wood for direct use in manufacturing industries and for making the crates and boxes which protect these products in transit. The extraordinary, and certainly not foreseen, development in the uses of wood pulp during the past century has made the forest the primary source of most of the world's paper and of a substantial proportion of its textiles. Wood chemistry is constantly developing entirely new products derived from wood. How great are these increased demands and what bearing have they on the existing forests and possibly newly created forests in the world ? For one thing, there is no longer the sharp distinction of utilization which formerly existed between the conifers and the hardwoods. Hardwoods are now converted and used in industry for purposes for which originally only the conifer was considered suitable. This is to the good; and modern machinery and research have made it possible to utilize some of the hardwood species of the mixed tropical forests previously regarded as valueless for commercial and, therefore, sale purposes. Incidentally, this will facilitate the sylvicultural working and management of some of these forests. The other advance which it is imperative should be made is to put an end, in the interests of the world community and not only of those of one particular country, to lumbering in all its forms, with its aftermath so often of bad erosion and destruction, the starting of fires in the debris on the lumbered area, and their spreading into valuable standing forests and often into townships and villages. In this respect the waste in some parts of the world has been enormous; and yet the method still continues in the interests of the few. Less spectacular, but equally serious, is the continuing practice of the removal of forest growing on true forest soils in order to make room for poor and unproductive farms; in the tropics vast areas of forest have been degraded or entirely destroyed by the cycle of shifting cultivation and annual firing followed by excessive grazing, leading to the production of desert condition. With the balance of Nature upset, anything may happen: erosion and loss of valuable top-soil, lowering of water-levels in the soil, floods and devastation caused by such at the lower land-levels.

The first essential steps to ensure the future forest reserves is for the nations to get together and determine the measures required to stop general forest destruction throughout the world. The forester responsible for the well-being and management of the respective forest areas, and the timber and other merchants who extract the varied commodities from the forest and take them to the market, will then all be in a better position to gauge the maintenance of the forest resources position.

A first attempt at a solution was made by Dr. Raphael Zon and Mr. William A. Sparhawk in the United States immediately after the First World War. Their publication of 1922 was followed up by further efforts on the part of Finland and Sweden and by the International Institute of Agriculture at Rome, which published estimates supplied by national Governments in year-books between 1933 and 1948. In 1946, available information on the world's forests was summarized in a report submitted to the second session of the Conference of the Food and Agriculture Organisation under the title "Forestry and Forest Products—World Situation 1937–1946". In the same year, Sir Hugh Watson made a study which appeared in the "British Empire Forestry Handbook".

All these attempts suffered from the inevitable chief drawback—the lack of reliable forest-inventory information, coupled with the lack of common forestry definitions.

How far has this deterrent affected the present publication ? At the first session of the Conference of the Food and Agriculture Organisation in the autumn of 1945, the need for knowledge of the forest resources of the world was recognized. Later, it was decided to issue a draft questionnaire to all countries, only questions essential to an appraisal of the forestry situation in each country being included. The preparation of such a document would not appear to offer much difficulty. But the reality was far different. Quite apart from the diversity of forestry definitions, all sorts of other difficulties had appeared, and the final form of the questionnaire was not approved until the meeting of the third session of the Conference at Geneva in August 1947. Even in that final form it was obvious that difficulties, if not ambiguities, remained; for example, for tropical countries, the filling up of such a form for a province in India, with its regulated forest-management extending over a period of eighty years, as compared with one of the South American States where forestry management has scarcely made an appearance.

Herein lies the danger of an attempt to draw up inventories of forestry resources which are based on world figures designed to form a basis for world production and for utilization for a world population, the growth of which in relation to the use of the forest resources available cannot be correlated. A census of the total world population is possible. But attempts at a similar census of the world's forestry resources, given our present actual knowledge of many of the last remaining forestry areas, as, for example, in the Latin American States, or the large area of forest in northern Russia and Siberia, must inevitably detract from the value of world figures. On the other hand, those figures obtainable for the comparatively small area of forest under a high or even modified forestry management will prove sufficiently accurate; but it is dangerous to take estimates based on such figures and apply them elsewhere to forests of which little is known. This has failed before. It is for similar reasons that calculations of the growth and volume of timber to be derived from plantations made on previously bare unafforested lands are likely to be incorrect.

Nevertheless, both the work and the information we have in this booklet are invaluable. At last the difficulties have been clearly seen and thoroughly grasped. Such items as land classification, classification of production forests, land ownership and volume of growing stock, all of them apparently simple divisions of the subject, produced divergencies of interpretation and meaning. Official statements respecting the forest resources of 101 countries and non-self-governing territories were received up to the date of publication. Additional questionnaires were expected, but the widespread interest aroused by the inquiry was considered to justify the publication of the present booklet. The tabular statements are ten in number and are entitled, respectively: response to inventory questionnaire; forested areas of the world; classification of productive forests; land classification; classification of productive forests, contd.; ownership of productive forests; growing stocks in accessible productive forests; average annual growth and annual drain for all species, for conifers only, for broad-leaved forests, respectively.

From the figures obtained, the authors of the report state that the forests of the world are capable of providing "reasonably adequate supplies" to a population larger than now exists. "But," they write, "the provision of such supplies will entail treatment of all productive forests as renewable crops, opening up of forests which are not yet accessible, and cessation of the widespread devastation of forests which, in this twentieth century, still continues."

If this is to come about, Governments, and their responsible ministers, finance members and treasuries, will have to regard the forest and its management as a very different proposition from that envisaged in the past. With the Governments responsible must be included large masses of the populations existing on the globe to-day; for without their intelligent co-operation in forest protection and management, inventories of forest resources may prove misleading and even dangerous. E. P. STEBBING

NON-UNIFORMITY OF THE EARTH'S ROTATION AND GEOMAGNETISM

By PROF. W. M. ELSASSER
University of Pennsylvania

THE existence of a secular deceleration of the earth's angular velocity at a rate

$$d\omega/dt = -2\cdot5 \times 10^{-22} \text{ sec.}^{-2} \qquad (1)$$

has long been established from astronomical data[1]. The classical work of G. H. Darwin and of Jeffreys, culminating in Jeffreys's computation of the frictional torque of the oceanic tide, seemed to have settled the theoretical aspects of the problem[2]. Later, de Sitter[3] and Spencer Jones[4] re-investigated the astronomical data. The value (1) is based on data from ancient eclipses and represents the average deceleration over the last two thousand years. Observations of the longitude of the moon, sun and planets over the past two hundred and fifty years show that the mean deceleration during this time was smaller than (1) —according to de Sitter 60 per cent, according to Spencer Jones 35 per cent of (1). Both the ancient and modern data seem trustworthy, and the conclusion is that a change in deceleration during the historical age is most probably real. Quite recently, it has been necessary to reopen the question as new geophysical information has become available. It can now be said that in all probability the deceleration of the earth is produced by two independent agencies: the oceanic tide, and a still very obscure effect in the earth's liquid core. While nothing is as yet known about the dynamics of motions in the core, there is good reason for believing that an appreciable fraction of the retarding torque operates in the core rather than in the oceans. This is perhaps close to the original ideas of Darwin, but the observations that lead to this conclusion are novel.

Let us first give a brief idea of the mechanics of the deceleration. We shall ignore the small solar tide as compared to the lunar tide. The angular momentum of the system earth–moon must be conserved. Darwin and Jeffreys have shown that the orbital motion of the moon takes up the angular momentum lost by the earth; the moon gradually recedes from the earth. Now the ratio of energy to angular momentum for the earth's rotation is $\frac{1}{2}\omega_e$; the same ratio for the moon's orbital motion is $-\frac{1}{2}\omega_m$. But $\omega_e/\omega_m = 28$, and it follows that per unit angular momentum transmitted to the moon, only 1/28 of the rotational energy of the earth is transmitted; the remainder must be used up by friction or other transformations of energy in the earth. The frictional forces produce a couple that retards the earth, and at the same time a force acts on the moon, tending to push the latter away from the earth. One of the more gratifying features of this theory is the fact that the observed deceleration is of the right general order to account for a gradual removal of the moon from an original position very close to the earth to its present distance during the known life-time of the earth.

The new evidence arises from rather unexpected quarters; it is based on geomagnetic observations. As we have endeavoured to show[5], the secular variation of the geomagnetic field can be explained by means of motions of the matter in the earth's fluid metallic core. Such motions induce electric currents in the core, of magnitude $I = \sigma v \times B$, where σ is the conductivity, v the velocity of the fluid, B the existing magnetic field. Bullard[6] has recently come to identical conclusions; he has, moreover, applied these principles to a study of the secular variation, with promising results. In general, an electromagnetic field in the presence of internal motions in a fluid conductor is non-conservative; energy is being exchanged between the field and the motion of the fluid. On the other hand, it can be shown[5] that so long as a parcel of the fluid moves without deformation, or if its deformation is negligible, it carries its electric currents and magnetic field with it unchanged except for the free decay of the currents. One immediate consequence of this is the fact that the observed irregular magnetic field rotates with the earth. Another important consequence will be indicated below.

We have recently come into possession of a most remarkable set of world-wide maps of the secular geomagnetic variation, constructed by Vestine and his collaborators[7]. These are based on an exhaustive evaluation of magnetic data and cover the period 1912–42 in intervals of ten years. The maps show that there are a number of centres of the secular variation scattered about the earth; these centres undergo rapid changes of intensity and also displacements of their position. The similarity of these maps and of ordinary weather charts is amazing, and there is no better way of conveying the idea that the secular variation owes its origin to fluid motions in the core than a contemplation of these maps. There are two independent ways in which the velocity of the fluid can be estimated, first by direct inspection of the displacement of the centres, and secondly from the rate of change of the field, using the electromagnetic theory[5,6]. Both methods give velocities of about 0·1–1 mm./sec. The most interesting feature, however, exhibited by these maps is a general *drift* of the whole pattern of the secular variation in the direction from east to west. It is difficult to assign an exact numerical value to this drift motion, since it is superposed upon the irregular displacement of the centres and is of the same order of magnitude as the latter. In order to have a convenient figure, we may estimate a value of 0·5°/year, which at the equator of the core represents a linear velocity of

1 mm./sec. Since this corresponds to an overall displacement of 15° over the period of thirty years covered by Vestine's maps, it is clear that the westerly drift is a conspicuous effect. There can be no doubt as to its reality. It occurred to us that if such a mean motion exists, it might not have escaped the attention of earlier students of the secular variation. In fact, Bauer[8] stated in 1895 that he found a "westerly wave" of the secular variation, and he traces it back to the middle of the sixteenth century. The mean angular velocity, so far as can be seen from his data, seems about half the value given above. The cause of the discrepancy is not clear; it is, no doubt, connected with the great irregularity of the secular pattern. Further corroboration of the effect may be found in the analysis of magnetic data of the sixteenth and seventeenth centuries by van Bemmelen[9].

On the basis of the theory which explains the secular variation as the result of fluid motions in the core, these observations must needs be interpreted as representing a bodily displacement of the core in the direction from east to west. This result agrees with the above-mentioned theorem, that the magnetic field is carried along unchanged if a bodily displacement of the conductor occurs. In spite of great efforts, we have been unable to devise any other even remotely satisfactory interpretation of the phenomenon. It will be noted that the direction of the drift is such as to indicate a *lag* of the core behind the rotation of the earth. This is the opposite of what one would expect if the earth were decelerated by a frictional torque in the oceans. From quite elementary considerations of mechanics one would expect the core to rotate faster than the mantle. The difference in angular velocity would be determined by the amount of eddy friction at the boundary of the core. Considering the magnitude of the velocities inferred from the secular variation, it seems likely that a turbulent boundary layer does exist at the surface of the core. (This view differs, however, from that of Bondi and Lyttleton[10], who assume laminar flow.)

Our first and natural reaction would be to try to explain away the phenomenon. As already noted, it would be practically impossible to explain it as due to cumulative or systematic errors in the observation. Students of meteorology might be reminded of the belts of alternating easterly and westerly winds which are a well-known feature of the atmosphere, and which adjust themselves so that the mean torque between the atmosphere and the solid earth vanishes. A careful study of Vestine's maps has not revealed any indication of an opposing drift motion; the existing westerly drift seems rather evenly distributed over the whole earth. Again, one might think that the present condition of the core is in the nature of a temporary deviation from its average state. If we assumed that there is no oceanic tide and that the core alone is decelerated at the rate given by (1), it is readily found that it takes 22,000 years to build up a difference in angular velocity of 0·5°/year. Since the mean life-time of the centres of the secular variation is much smaller—a few hundred years at the most—it seems well-nigh impossible to interpret the westerly drift motion as a mere fluctuation.

Hence we must conclude that the earth's core actually rotates more slowly than the solid 'mantle' surrounding it. It follows at once that, owing to eddy friction at the boundary of the core, angular momentum migrates from the mantle into the core. The core must continuously lose angular momentum, and this is impossible unless there is a direct gravitational interaction between the core and the moon such that the angular momentum lost can re-appear in the orbital motion of the moon. Perhaps the interpretation of these results is facilitated by the recent discovery[10] that the core is not homogeneous but contains a central body of as yet unknown constitution. This is indicated by the peculiar behaviour of seismic waves at great depths. The boundary of this central body seems the natural locus of any tidal effects in the core.

It is one of the results of the theory of tidal friction that the dissipation in deep seas is negligibly small. The frictional effects of the oceanic tide computed by Jeffreys[11] arise in shallow basins such as the Bering Sea, the Irish Sea, etc. It is in the nature of such a theory that no great numerical accuracy can be expected from it. We have just indicated that in place of one retarding couple acting on the earth there are two, one in the oceans and one in the core. It is difficult to estimate the relative magnitude of the two, as Jeffreys's theory of tidal friction can scarcely afford a quantitative clue. The moment of inertia of the core is about one tenth of that of the earth. Hence if the 'inner' couple decelerated the core alone, and the 'outer' couple acted on the mantle alone, their ratio would be 1 to 10. Since, however, angular momentum migrates into the core, the inner couple must actually be larger. Just what fraction of the whole retarding torque it constitutes can only be said when it becomes possible to estimate the magnitude of the eddy friction at the boundary of the core. Given the great variability of the secular magnetic field and the inference from it that the motions in the core are highly unstable, an explanation of a change in the earth's deceleration might well be sought along these lines rather than by the assumption of a change of friction in the oceanic tide.

The existence of the westerly drift motion throws an entirely new light on the physics of the earth's interior. It strongly corroborates the theories which connect the phenomena of geomagnetism with fluid motions in the core, in that it reveals the existence of a supply of power for the maintenance of such motions throughout the life of the earth. It has been shown[5,6] that the magnetic field in the interior of the core must be much stronger than the field at the outside, and the energy of this internal field is supplied directly by the fluid motion. Numerical estimates make it appear possible that the conversion into magnetic field-energy replaces mechanical friction in the core as the agent productive of the retarding torque. Whatever the ultimate outcome of these theories, it seems certain that the discovery of the westerly drift motion by Vestine opens up a new branch of geophysical dynamics.

OBITUARIES

Dr. H. J. van der Bijl, F.R.S.

Dr. Hendrik Johannes van der Bijl, whose death occurred on December 2, was born in 1887. From early childhood he showed that he was of stern stuff and would be different from others. A successful stay at the University of Stellenbosch concluded with a B.Sc. honours degree. He proceeded to Germany, where, at the University of Halle, he obtained the degree of M.A., to be followed later on by the Ph.D. of the University of Leipzig. It was while he was instructor in physics at the Royal School of Technology at Dresden that he came in contact with Prof. R. A. Millikan, who had gone to Germany to deliver a lecture on an aspect of physics with which van der Bijl was also dealing at the time; this meeting laid the foundation for van der Bijl's meteoric career. So impressed was Prof. Millikan that on his return to the United States he advised the Western Electric Company, New York, to employ the serious young South African to pursue research on the triode, which had recently been invented by Lee de Forest, and was just being applied in the fast-developing art of radio.

Van der Bijl's success was remarkable; it came as the result of an indomitable will to accomplish and an uncanny insight into the workings of thermionics, which he had made his special study in Germany. His promotion was deservedly rapid, and he would undoubtedly have left an even greater mark in the United States had he not lent an ear to the cry of his native land in the person of General J. C. Smuts.

So he became technical adviser on industrial development to the Department of Mines and Industries of the Union of South Africa. Apart from a new Weights and Measures Act, he busied himself in the preparation of the proposed Electricity Supply Act of 1922. Like the slumbering industrial giant in the United States which was first awakened by the First World War, so the Union of South Africa was activated from her slow farming and easy gold-mining economy into the first gropings for an industrial economy. Fortunate indeed was it for the Union that it had van der Bijl, with his great natural gifts and unique technical training, his insight into the future, his willingness to dare, his determination to succeed and his genius for planning.

The establishment and success of the South African Iron and Steel Corporation followed in 1928, and by 1947 he had sponsored and developed numerous other projects.

Van der Bijl's early scholastic attainments have already been mentioned; in addition he held the honorary degrees of D.Sc. of the University of Stellenbosch and LL.D. of the University of Cape Town. He was a member of the American Institute of Electrical Engineers, fellow of the Institute of Radio Engineers, fellow of the Royal Society of South Africa, honorary member of the Koninklyk Instituut van Ingenieurs (Holland), foreign associate of the U.S. National Academy of Science, and fellow of the Royal Society. He was also chancellor of the University of Pretoria. He was the author of a large number of scientific and technical works in German and English published in Germany, America and South Africa. His book, "The Thermionic Vacuum Tube, and its Applications", published in 1920, was at the time the best of its kind in the English language.

His industrial career includes a long list of successful chairmanships and directorships. At the time of his death he was chairman of the Electricity Supply Commission, of the South African Iron and Steel Corporation, chairman and managing director of the African Metals Corporation, Ltd., and of many other bodies. As director-general of war supplies and, later, director-general of supplies during the Second World War, he continued and nursed on the road to completion the industrial development of his homeland, which as technical adviser he helped to initiate in 1920. It is worth recording that the British Government consulted him on its proposed bill for the nationalization of the steel industry in Britain.

The confidence South Africa had in his integrity and ability was remarkable, and he inspired all with whom he came in contact with his ebullient optimism and dynamic activity. In the endeavours for the success of his undertakings it was a fight to glorious victory—or destruction. His end came on December 2, at the peak of his career; he was utterly exhausted by a full and exacting life and by a merciless illness.

J. Theo. Hattingh

Rev. J. P. Rowland, S.J.

We regret to record the death of Father James Peter Rowland, until recently director of Stonyhurst Observatory. Father Rowland was a native of Blackburn, born on June 29, 1875; he was educated at Mount St. Mary's College, near Sheffield, and joined the Society of Jesus in September 1894. In October 1919 he was appointed assistant at Stonyhurst Observatory, and became its director in 1932. He was a member of several learned scientific societies, including the Royal Astronomical and Royal Meteorological Societies.

To the general public, especially in East Lancashire, Father Rowland was known chiefly for his weather forecasts, which were published in the local evening papers, and gained a high reputation for accuracy. To the scientific world, however, his work in seismology was of more importance. Considering, indeed, the limitation imposed by a single Milne–Shaw instrument and the difficulties of the situation, Father Rowland's work was remarkable for its accuracy, and won for him a position among the seismologists of Great Britain. He had two notable successes, in the location of the epicentres of the North Sea earthquake of 1931, and the Wensleydale earthquake of 1933, on the latter of which he read a paper before the British Association.

His other work at the Observatory included the routine magnetic observations, the routine solar observations and occasional astronomical work. All these were remarkable for their accuracy, attained in many instances in spite of the difficulties in the accurate use of old-fashioned instruments. It is to be regretted that there is so little published matter connected with his name. In 1933 he published in the *Monthly Notices of the Royal Astronomical Society* the results of his observations of the period of rotation of the planet Saturn, which probably give the value of this as definitively as is at present possible. There are two papers in his name in the *Monthly Notices* on solar and magnetic work, and during his directorship of the Stonyhurst Observatory he was responsible for the Observatory's Annual Report; but apart from these, his publications are no more than brief notes. Nevertheless, in the course of years of routine observation, especially on sunspots and terrestrial magnetism, he amassed a quantity of material which it is hoped will one day be subjected to profitable analysis.

As a man, Father Rowland had great charm of manner and made many friends, and there was a whimsical mournfulness about him which never failed to amuse those who knew him intimately. He took endless pains to answer the queries of those who wrote to him for information, and in his priestly work was a zealous and sympathetic helper of souls. Towards the end of his life he became rather prematurely aged and enfeebled, and, at the close of 1947, had to retire from all active work. The end came sooner than was expected. He collapsed and was taken to hospital on December 19, and died rather suddenly on the morning of December 26.

WE regret to announce the following deaths:

Prof. C. O. Bergstrand, formerly professor of astronomy in the University of Uppsala, on September 27, aged seventy-five.

Prof. Torsten Carleman, professor of mathematics in the University of Stockholm, on January 11, aged fifty-six.

Prof. Walter Garstang, emeritus professor of zoology in the University of Leeds, on February 23, aged eighty-one.

Prof. Douglas Hay, chief mining engineer (management) of the National Coal Board and president of the Institution of Mining Engineers, on February 24, aged sixty.

Prof. Richard C. Tolman, of the California Institute of Technology, vice-chairman of the U.S. National Defense Committee, on August 14, aged sixty-seven.

NEWS and VIEWS

The Crisis in Soviet Science

LAST August scientific workers all over the world heard with deep disappointment that the Soviet Union had officially adopted an isolationist attitude on certain branches of biology. For the first time in the U.S.S.R. there was established a 'party line' in one of the natural sciences. Since then there has been speculation as to whether this attitude might extend to other natural sciences, and a recent broadcast from Moscow gives point to these speculations. On January 26, 1949, the philosopher Alexander Alexandrovitch Maximov, who is a corresponding member of the Academy of Sciences, and who belongs to the staff of its Institute of Philosophy, gave a broadcast on the Moscow Radio Home Service. The theme of his talk was the correct Bolshevik attitude to natural science. He attacks those foreign physicists who "regard as synonymous the philosophical definition of matter and the objective idea of reality", and who are responsible for other "idealistic misinterpretations" in relativity and quantum theory. He indicts by name Einstein, Niels Bohr and Heisenberg. He warns his listeners against the "Kantian acrobatics of modern bourgeois atomic physicists". He contrasts the ideology of these "social traitors" in capitalist countries with the scholars in capitalist countries who "raise their voice in support of genuine science, of a scientific materialist outlook"; and he cites with approval Langevin, Joliot-Curie, Blackett, Haldane and Levy. The purpose of the broadcast was twofold: (*a*) to emphasize the importance of a correct philosophical approach to physics, based on Lenin's famous "Materialism and Empiriocriticism", and (*b*) to encourage an attitude of "militant intransigence towards bourgeois idealistic philosophy and sociology".

Botany at Bangor: Prof. D. Thoday, F.R.S.

PROF. D. THODAY retires from the chair of botany at the University College of North Wales, Bangor, on September 30. After graduating at Cambridge, he carried out researches on photosynthesis under the late Dr. F. F. Blackman before going to the University of Manchester as lecturer. Thence he became professor of botany at Cape Town in 1918 and returned to Bangor in 1923. Prof. Thoday has successfully combined arduous teaching duties with active research, in which he has made notable contributions in several fields—the water-relations of plants, plant development and differentiation, and the physiology of succulents. In South Africa he was much interested in the native plants, and several of his investigations concern them; in this connexion he revised the genus *Passerina*. He was president of Section K of the British Association meeting at Dundee in 1939, when he gave a stimulating address on the interpretation of plant structure.

During his tenure at Bangor, Prof. Thoday has seen great developments in his Department, for which he has been chiefly responsible. New laboratories were built in 1926; but these were already congested by 1939 when, owing to the War, accommodation had also to be found for the botany students and staff of University College, London. The latter are grateful for his assistance at a critical time. Plans are now under way for a new building to house the Departments of Botany and Forestry. At Bangor there is intimate contact between these Departments and also that of Agricultural Botany, which Prof. Thoday has greatly fostered, especially as regards instruction in plant physiology and ecology. His staff have made important contributions to the ecology of North Wales and to the algal floras of the area. He has warmly supported Prof. Brambell's plea for a marine biological station on the Menai Straits, now happily being brought to fruition. Both as dean of the College faculty of science and in other ways, Prof. Thoday has taken an active part in College and University administration. On retirement, Prof. Thoday hopes to publish his researches on the developmental physiology and morphology of the mistletoe (*Viscum album*), on which he has been engaged for some years, and to carry out further investigations on other members of the Loranthaceæ in South Africa and elsewhere.

Prof. P. W. Richards

DR. P. W. RICHARDS, university lecturer and former fellow of Trinity College, Cambridge, has been appointed to succeed Prof. Thoday in the chair of botany at Bangor. His chief interests are in plant ecology and the Bryophyta, and he will have abundant opportunity for their pursuit in one of the richest regions of Great Britain for such studies. Dr. Richards has been a valuable member of the staff of the Cambridge Botany School since 1937, where he has been responsible for the organisation of the practical classes for first- and second-year students and has taken a principal part in lecturing to them. A noteworthy feature of his teaching has been his wide outlook and his insistence on the study of plants in the field; in this connexion he has conducted many vacation classes in the Lake District and elsewhere. He is one of the editors of the Ecological Society's "Biological Flora of the British Isles", and has encouraged much research on interesting plants.

Dr. Richards has travelled extensively in connexion with his studies of tropical rain forests. In 1929 he was in British Guiana, in 1932 he visited Sarawak, and during 1934–35 and 1947–48 he was the leader of Cambridge botanical expeditions to Nigeria. In addition to publishing papers on various aspects of tropical rain forests he has written a comprehensive book about them, now in course of publication. As a bryologist, Dr. Richards is outstanding, and he is convinced that mosses and liverworts offer a favourable field, hitherto largely unexplored, for experimental studies. He has taken great interest in the Cambridge Botanic Garden. His Cambridge colleagues, while regretting Dr. Richards's departure, congratulate him warmly on his advancement. They prophesy that he will have a very successful tenure of the chair at Bangor. With large developments pending there, Dr. Richards's organising ability and co-operative nature should be valuable assets.

Engineering at Manchester: Prof. A. H. Gibson

PROF. A. H. GIBSON is to retire from the Beyer chair of engineering in the University of Manchester in September. He will then have occupied this famous chair for twenty-nine years, with a distinction well worthy of the traditions created by his master, Osborne Reynolds. Both at Manchester and in his inspiring re-organisation of the Engineering Department of the University of St. Andrews between 1909 and 1920, Prof. Gibson has maintained a firm belief in Reynolds's conception of the aims and methods of university education in engineering: to teach fundamentals and "the physical laws on which mechanics as a science are based"—and to eschew 'spoon-feeding'. His original work is described in an impressive series of books and papers remarkable for the clarity of his writing, the directness of his arguments and the skill of his experimenting. A very few titles taken at random reflect the range of his interests: "On the Depression of the Filament of Maximum Velocity in a Stream flowing through an Open Channel"; "On the Local Intensification of Draught produced in a Horizontal Air Current by the Presence of an Inclined Rod"; "A Study of the Circular-Arc Bow Girder"; "The Behaviour of Bodies Floating in a Free or a Forced Vortex"; "Piston Temperatures and Heat Flow in High Speed Petrol Engines"; "Tidal Model of the Severn Estuary".

Prof. Gibson was for a time simultaneously a member of the Severn Barrage Committee and of the Air Ministry Engine Research Committee. Since 1926, however, his special interest has been in the use of hydraulic scale-models, and a natural outcome of his great efforts in this field was the establishment in 1946 of the Hydraulics Research Organisation of the Department of Scientific and Industrial Research. At the present time, no fewer than six university chairs are occupied by former students and members of his staff, and his personal influence among students and practising engineers alike is as significant as (to quote the citation of the Ewing Medal awarded to him in 1938) his "specially meritorious contributions to the science of engineering in the field of research".

Prof. W. R. Hawthorne

WILLIAM REDE HAWTHORNE, who is succeeding Prof. A. H. Gibson, was educated at Trinity College, Cambridge. He obtained first-class honours in the Mechanical Sciences Tripos and was awarded the Rex Moir Prize. On leaving Cambridge he joined the firm of Babcock and Wilcox, where for a short time he worked on boiler research. He then obtained a Commonwealth Fund Fellowship, which enabled him to go to the United States and work for two years at the Massachusetts Institute of Technology on combustion research. On the completion of this work he returned to England to his old firm. When the Second World War broke out he joined the research staff of the Air Ministry, being later transferred to the Ministry of Aircraft Production. He worked for a short time at the Aircraft Testing Establishment at Boscombe Down and then moved to the Engine Department of the Royal Aircraft Establishment at Farnborough. At Farnborough he was quickly drawn into the work proceeding there on gas turbines, and in a short time was put in charge of this work. In 1944 Dr. Hawthorne was transferred to the headquarters branch of the work, where he became responsible for directing the work on gas turbine research. At the end of the War he returned to the United States and took up a post as lecturer at the Massachusetts Institute of Technology, where he is at present the Westinghouse professor of gas turbines. Prof. Hawthorne is known for the researches directed by him on gas turbines during the War and for his interest in the combination of fluid flow and combustion usually termed 'gas dynamics'.

Scientific Civil Service: Promotion of Individual Research Workers

IT is announced that additional special posts have been created this year for individual research workers of exceptional quality under provisions included in the White Paper on the Scientific Civil Service (Cmd. 6679, 1945). In recognition of their personal work, promotion to these posts in the grade of senior principal scientific officer (salary scale, £1,320–£1,520) has been awarded to the following officers: C. A. Adams (Ministry of Supply), a mathematical physicist whose researches in ballistics and in ultra high-speed photography have led to results of the highest importance; Dr. H. A. Baylis (British Museum (Natural History)), a systematic zoologist, who has made notable contributions to our knowledge of the parasitic worms, particularly those of importance in medical and veterinary work; Miss F. B. Bradfield (Ministry of Supply), whose numerous contributions in aerodynamics to aeronautical research have been of outstanding scientific and industrial value; H. C. Calpine (Admiralty), a pioneer in radar, who has contributed in a large measure to the successful development of naval fire-control radar, and is now engaged on research into the difficult problems of weapon control; W. G. Campbell (Department of Scientific and Industrial Research), who has made many original contributions to the chemistry of wood, some of considerable technical importance; J. N. Carruthers (Admiralty), whose investigations on tidal currents have earned for him an international reputation, and who has brought together a valuable oceanographical library; J. S. Dick (Ministry of Supply), a physical chemist and a leading authority on pyrotechnics who has a long record of outstanding achievements in this field; J. W. Fisher (Admiralty), who is engaged on theoretical and experimental investigations in hydrodynamics and acoustics with special application to the reduction of ship noise and to the examination of cavitation phenomena; H. L. Green (Ministry of Supply), who has made important contributions to the study of particle suspensions and has developed this branch of physics to a very high degree of precision; J. S. Hey (Army Operational Research Group, War Office), who, in the course of his work on radar and the ionosphere, has carried out important investigations on abnormal radiations from the sun and the galaxy and on echoes due to meteors; Dr. H. London (Ministry of Supply), a physicist whose outstanding work before the War was on the effect of high frequencies on supra-conductivity; more recently, he has worked on the separation of stable isotopes, and has achieved results of considerable practical and theoretical importance in the separation of carbon-thirteen by low-temperature distillation; A. R. Rangabe (Admiralty), who was concerned prior to the War with the development in industry of electronic tubes of all descriptions; his ingenuity and flair for developing manufacturing techniques, and his understanding of the problems and difficulties in manufacture, have particular significance at the present time; Dr. E. Roberts (Ministry of Supply) has a long and successful record of important and fundamental work on diverse aspects of the chemistry and production of explosives.

National Institute of Sciences of India: New Fellows

At the meeting of the National Institute of Sciences of India on January 4, 1949, the following elections were announced. *Honorary Fellows:* Prof. Louis de Broglie, professor of theoretical physics, Poincaré Institute, Sorbonne, Paris; Prof. Hans von Euler, emeritus professor of chemistry, University of Stockholm; Dr. Harlow Shapley, director of Harvard Observatory, Cambridge, Mass.; Prof. Georg Tischler, Botanical Institute, University of Kiel. *Ordinary Fellows:* Dr. J. L. Bhaduri, lecturer in zoology, University of Calcutta; Dr. S. Bhagavantam, scientific liaison officer for India in the United Kingdom; Dr. S. K. Chakrabarty, director, Colaba and Alibag Observatories, Bombay; Dr. D. Chakravarti, lecturer in chemistry, University of Calcutta; Dr. M. Damodaran, assistant director, National Chemical Laboratories, Delhi; Dr. B. K. Das, professor of zoology, Osmania University, Hyderabad-Deccan; Dr. Kurien Jacob, palæobotanist, Geological Survey of India, Calcutta; Dr. T. S. Mahabale, lecturer in botany, Royal Institute of Science, Bombay; Dr. H. K. Mitra, refractories engineer, Tata Iron and Steel Co., Ltd., Jamshedpur; Dr. K. Mitra, officer in charge, Nutrition Scheme, Public Health Laboratories, Patna; Dr. A. H. Pandya, director, Hindusthan Aircraft, Bangalore; Dr. N. Parthasarathy, geneticist, Indian Agricultural Research Institute, New Delhi; Dr. C. Racine, professor of mathematics, Loyola College, Madras; Dr. K. C. Sen, director, Indian Dairy Research Institute, Bangalore; Dr. R. S. Varma, reader in mathematics, University of Lucknow.

Production of Radioactive Isotopes in Britain

The large atomic pile (BEPO) at the Atomic Energy Research Establishment, Harwell, has begun operating for the production of radioactive isotopes. When it is working at full power later this year, it will be able to produce all the artificial radioactive isotopes required in Great Britain by medical, industrial and other research workers. More isotopes will also be available for export, and it is expected that a steadily increasing demand for them will develop overseas. Materials irradiated in the new pile will be twenty times more active than those so far irradiated in the first and smaller pile. The new pile has a rated output of 6,000 kW. and was designed primarily for experimental purposes. The smaller pile, designed to develop about 100 kW. of heat, started up in August 1947 and has been producing radioactive isotopes since September of that year. Present production is about a hundred and fifty specimens a month.

Vegetation-types Map of Tanganyika

The *Geographical Review* has published a reprint of an article from the January 1949 issue entitled "A Vegetation-types Map of Tanganyika", by the late Clement Gillman. This study of the natural vegetation of Tanganyika Territory by a man who had profound knowledge of the country and of its people is one that should be used as a basis for wise planning, and development. The classification is strictly physiognomic and provides an essential basis for further ecological and geographical investigations. The vegetation of the greater part of Tanganyika Territory is a mixture of woodland or bushland with grassland, the distribution being primarily determined by variations of soil and water conditions and the use made of them by man, although, as the author points out, topography and tectonics influence the climate and distribution of vegetation. The main types shown on the coloured map on a scale of 1 : 2,000,000 include forest, woodland, bushland and thicket, grassland, permanent swamp vegetation, desert and semi-desert, and vegetation actively induced by man in native and non-native cultivations. The term "actively induced vegetation" includes the mixed and constantly changing pattern of cultivated crops, pastures and interspersed remnants of the original vegetation and of scattered small areas of secondary growth. Complexes of vegetation occurring in close conjunction are shown on the map symbolically, using the colour of the dominating type for the ground colour with intrazonals or complexes shown by circles or dots in the colour of their type. Sequences of vegetation types caused by regularly repeated physiographic or hydrographic conditions are shown as "catenas"—a word originally applied to soils in East Africa. The map brings out at a glance the small remnants of evergreen forest left on the main watersheds, and the author stresses the urgency of the threat to the country's water resources. The map also rectifies a commonly held exaggerated view of the size of alien plantations and farming settlements, which appear as tiny specks compared with the great extent of native-cultivated land.

Statistical Estimation

The current mathematical theories concerned with the estimation of one or more unknown parameters in a frequency distribution have been the occasion of much controversy, and the absence of a systematic review of this field at a sufficiently elementary level has been a serious obstacle to the student. Two recent articles by Dr. Leon Solomon published in the *Journal of the Institute of Actuaries Students' Society* (**7**, 144 and 213) go a long way towards meeting this need, and form a most welcome addition to the literature. The first article is chiefly concerned with 'point' estimation. The concept of sufficiency is discussed, the minimum-variance theorem is proved, and the method of maximum likelihood is introduced, the proofs of its main properties being given in outline. The second article is concerned with 'interval' estimation, first from the point of view of the theory of confidence intervals and then in terms of fiducial probability, the contrast between these two methods of approach being illustrated by a discussion of the Behrens–Fisher problem. Rigorous proofs of the theorems are not attempted, and the emphasis throughout is laid on the new ideas which are involved. Another welcome feature of the presentation is the inclusion of many worked examples.

Chemical Society's Anniversary Meeting: Chemistry and Atomic Research

THE Chemical Society is holding its anniversary meetings for 1949 in Oxford, during March 28–30, and then in London, during March 31–April 1. The keynote throughout these meetings will be the recent chemical developments in the field of atomic energy and the way in which radioactive elements may be used in chemical and biochemical investigations. A noteworthy feature is that the Ministry of Supply has invited a number of distinguished men of science from Europe and America to participate in the general discussion and interchange of ideas; it is expected that the following will be present: Prof. R. E. Connick, Prof. J. W. Irvine, Dr. G. Wilkinson (United States); Dr. G. Bouissères, Dr. J. Gueron, Dr. B. Goldschmidt, Dr. M. Haissinsky (France); Dr. L. Yasse, Dr. R. H. Betts (Canada); Prof. O. Hahn, Dr. F. Strassman (Germany); Prof. G. Hevesy (Denmark); K. E. Zuimen, H. Hillert, G. Johannson, E. Berne, R. Lidner (Sweden). The Oxford meeting, at Rhodes House, South Parks Road, will be devoted principally to a symposium on "The Chemistry of the Heavy Elements", consisting of four sessions under the chairmanship of Dr. R. Spence (for the first two), Dr. E. Glueckauf and Dr. J. S. Anderson respectively. This symposium has been arranged in conjunction with the Chemistry Division of the Atomic Energy Research Establishment, and the programme will include a visit to Harwell. In addition, there will be two sessions on "Radioactive Tracers", the first session, "Preparation", being under the chairmanship of Dr. J. M. Fletcher, and the second, "Nuclear Aspects", under Dr. W. Wild. March 31 will be devoted to the annual general meeting of the Chemical Society, and this will be held at Burlington House, London, W.1. The Longstaff Medal will be presented to Sir Cyril Hinshelwood, and this will be followed by Sir Ian Heilbron's presidential address: "Concerning Amino-Acids, Peptides and Purines". On April 1, at the Institution of Civil Engineers, Great George Street, London, S.W.1, there will be a discussion on "The Use of Radioactive Tracers in Chemistry". This will be divided into two parts: the first, on "Applications in Inorganic and Physical Chemistry", with Prof. F. A. Paneth in the chair, and the second, on "Applications in Organic Chemistry and Biochemistry", with Prof. G. Hevesy presiding.

Acoustics Measurements on Church Bells

DURING the Second World War, when the Germans occupied Holland, they ordered that church bells should be collected to provide a source of bronze for war prospects. This plan met with great resistance from the Dutch, so that after the liberation, several hundreds of bells of different origin and ages, which had escaped being melted down, were gathered at a number of places. At the end of the War, the Dutch Department for Research in Arts and Measurements took the opportunity to collect complete information on the æsthetic and acoustical properties of these bells, many of which were two or three hundred years old. Part of this work was carried out by E. W. van Heuven, who is to read a paper on this investigation at a meeting of the Acoustics Group of the Physical Society, to be held at the Royal Society of Arts, John Adam Street, London, W.1, on March 18 at 3 p.m.

Announcements

THE Committee for Agricultural Research of the Privy Council has appointed Prof. James Gray, professor of zoology in the University of Cambridge, to be a member of the Agricultural Research Council. This is Prof. Gray's second term of office as a member, his first being during 1942–47.

IT is announced from the University of London that Dr. J. H. Taylor has been appointed to the University chair of geology tenable at King's College as from October 1, 1949. The following doctorates have been conferred: *D.Sc.* on Mr. R. L. Wain (reader at Wye College); *D.Sc.(Eng.)* on Mr. A. R. Collins (Imperial College of Science and Technology).

MR. A. L. FLEET, formerly assistant secretary and registrar of the University of Bristol, has been appointed assistant secretary of the Association of Universities of the British Commonwealth, the office of which is now at 5 Gordon Square, London, W.C.1.

THE Rouse Ball Lecture in the University of Cambridge will be given by Prof. W. Pauli, of Zurich, at noon on March 10. His subject will be "Physical and Mathematical Aspects of Recent Developments in Quantum Electrodynamics". The lecture will be in English and open to all who are interested.

A MEETING at Göttingen of the Deutsche Bunsengesellschaft für physikalische Chemie has been arranged for April 23–24, 1949.

THE Institute of Welding and the British Welding Research Association are arranging a Conference on "Welding as an Aid to the Saving of Steel and Manpower", to be held at Ashorne Hill, near Leamington Spa, during March 22–25. Applications for tickets and all correspondence should be addressed to the Secretary, Institute of Welding, 2 Buckingham Palace Gardens, London, S.W.1.

UNDER the terms of a grant from the Cotton Industry War Memorial Trust, the Textile Institute is offering to young craftsmen in the cotton spinning and weaving industry a three-year scholarship (of about £750 total value) to study textiles at a university. This scholarship is in addition to the new £1,000 open scholarship of the Institute. Details of both scholarships are available from the General Secretary, Textile Institute, 16 St. Mary's Parsonage, Manchester 3.

THE Institution of Naval Architects is offering the following scholarships to British subjects less than nineteen years of age: Trewent, for naval architecture, £175 a year, tenable at the Universities of Durham, Glasgow, Liverpool, and the Royal Naval College, Greenwich, for 3–4 years. Denny, for marine engineering, £130 a year, tenable for four years at the University of Glasgow. Entries for the above close on May 31. Full particulars may be obtained from the Secretary of the Institution of Naval Architects, 10 Upper Belgrave Street, London, S.W.1.

Measurement of Sperm Activity before Artificial Insemination

THE successful application of artificial insemination largely depends on the possibility of making a quick assessment of sperm activity in the sample of semen to be employed. The existing methods of assessing sperm activity suffer from certain disadvantages. They are either subjective, depending on the judgment of an individual who has often examined semen under the microscope, or they involve chemical treatment which may take some time to complete. The most satisfactory is the fructolytic test, which not only gives a combined measure of sperm motility and density[1], but also provides an indication of the hormonal (testosterone) activity of the bull[2]. On the other hand, samples have to be taken from the ejaculate and incubated at 37° C. for one to three hours.

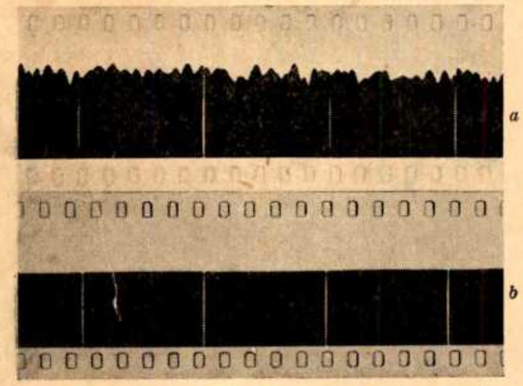

Fig. 1(*a*). Impedance of ram semen containing active spermatozoa. (*b*) Impedance of the same semen after spermatozoa have become motionless. Time-marker, 30 sec.

These difficulties are avoided to a considerable extent by an electrical method of assessing sperm activity. The method is based on the observation[3] that ram semen, when active, exhibits well-defined periodic changes in electrical impedance (Fig. 1). As a result of the experiments on ram semen it was predicted that analogous electrical changes in the semen of other mammals might be too small to observe, or non-existent, unless the density of the sperm were augmented by centrifugation. It has, however, been possible to observe and measure the electrical changes in bull semen with a portable apparatus. Experiments to determine the relative merits of this and other methods of assessing sperm activity have been started; but as these may involve correlating conception-rates with assessments of sperm activity determined in different ways, the results may be considerably delayed.

The apparatus for measuring the electrical changes is mains-operated and consists of a conventional alternating current bridge, energized by a 5-kc. oscillator. The detector is an oscilloscope with amplifier. The method of presenting the data on the oscilloscope is largely a matter of personal choice. For visual observation the electrical changes are usually made to tilt or widen an elliptical trace on the screen. A pair of platinized platinum electrodes (Fig. 2) dip into the semen, in a test-tube or centrifuge tube, preferably in a 'Thermos' flask containing water at 37° C. This forms the unknown arm of the bridge, the voltage across it being about 50 millivolts. Trials are in progress to determine whether this treatment has any influence on the fertilizing capacity of the spermatozoa. At the beginning of an experiment, the resistance and capacity of the unknown arm are approximately balanced. If the semen is fresh and the sperm both active and sufficiently dense, periodic impedance changes, which have the following characteristics, are observed: (1) The frequency is maximal immediately the semen has been collected (Fig. 1*a*). (2) When the sperm are dead or only feebly motile, the frequency is zero (Fig. 1*b*). (3) The frequency is reduced by lowering the temperature, and vice versa. (4) The initial frequency can be maintained by adding phosphate buffer to the semen; this treatment also maintains the fructolytic activity at a high level[1]. (5) The changes can be markedly amplified by increasing the sperm density of the sample.

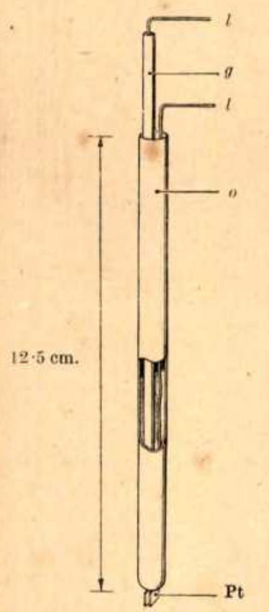

Fig. 2. Electrodes for use with bridge. **Pt**, platinized platinum plates; *l*, leads to bridge; *g*, insulating glass tubing; *o*, outer glass tubing

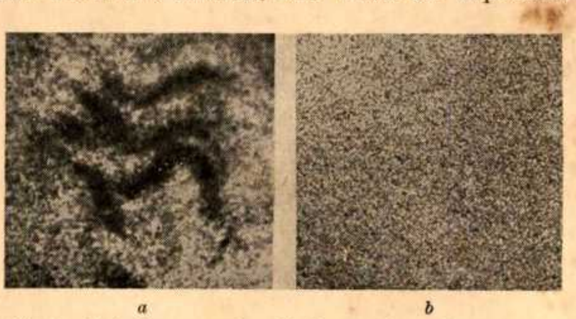
These impedance changes are unlikely to be caused by alterations in the electrical characteristics of individual spermatozoa, such as take place in a contracting muscle fibre; they are probably due to periodic variations in the positions of sperm in the measuring system. The changes are believed to be connected with the 'turbulent wave formation' that is characteristic of active and dense suspensions of bull or ram spermatozoa (Fig. 3). This wave formation represents a periodic aggregation of spermatozoa, the tails of which probably beat synchronously in the aggregations.

The electrical method of measuring sperm activity has the following advantages: (1) Measurements can be made on the semen while still in the glass receptacle at the end of the artificial vagina, or, if necessary, on a separate $\frac{1}{2}$ c.c. sample. (2) Measurements take about five minutes, after which an 'impedance



a *b*

Fig. 3. (*a*) Active suspension of bull spermatozoa showing wave formation. Magnification, approx. 40. (*b*) The same suspension of bull spermatozoa after activity has ceased. Magnification, approx. 40

number' (number of spikes/min.) can be assigned to the sample. (3) The method is quantitative and non-subjective. Photographs can be taken for record purposes. (4) The apparatus is portable, and the method of operation can be learnt in a few hours.

The main shortcomings of the method are, first, that it will not provide an assessment of activity unless the semen is sufficiently dense. This may not be serious, as whenever wave formation occurs in semen, impedance changes are observed. Wave formation is usually accepted as a necessary characteristic of semen for use in artificial insemination[4]. Secondly, although the evidence suggests that the frequency of the impedance changes is proportional to sperm activity, further experiments, and, in particular, parallel measurements of fructolysis, impedance numbers and conception-rates, are necessary before the practical value of this method of assessing sperm vitality can be finally established.

A word of warning is perhaps necessary about the assessment of the fertilizing capacity of sperm samples from measurements of sperm activity. Many other factors, apart from the ability to move fast, go to make up the fertilizing capacity of a spermatozoon. If this were not so, intergeneric crosses would be possible. Equally, metabolism and motility are not necessarily related to each other in a simple way. Mann and Lutwak-Mann[5] have shown that, in ram semen, both motility and fructolysis can be inhibited by sodium fluoride without respiration being affected to the same extent, while I have found[6] that the oxygen uptake of sea-urchin spermatozoa can be greatly reduced by carbon monoxide without any corresponding decrease in motility.

This work has been carried out in close co-operation with Dr. T. Mann of the Molteno Institute, Cambridge, Dr. L. E. A. Rowson of the Artificial Insemination Centre, Cambridge, and Dr. A. Walton of the Animal Research Station, Cambridge. Part of the cost of this work was defrayed by a grant (March 11, 1948) from the Agricultural Research Council to the Department of Zoology, Cambridge, for a laboratory assistant.

Photosynthesis in Leaves at Very Low Carbon Dioxide Concentrations

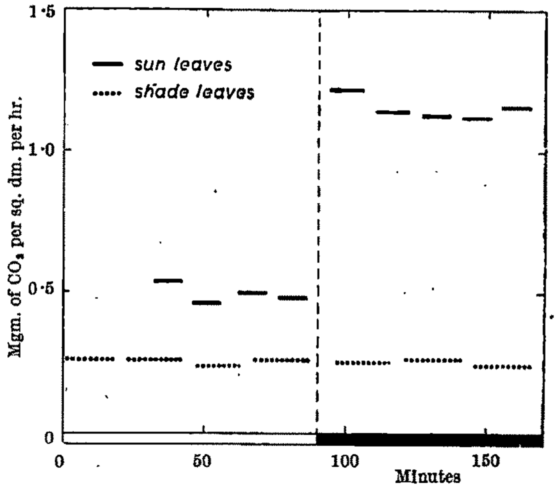
THE photosynthesis of foliage leaves in air free from carbon dioxide is restricted to a re-assimilation of the carbon dioxide which originates from the respiratory process.

Garreau, in the middle of the nineteenth century, demonstrated that green leaves expired carbon dioxide in glass chambers containing small shallow dishes with lime water, or barium hydroxide, when they were exposed to diffuse daylight[1], or even direct sunshine[2,3], that is, the re-assimilation was not complete in surroundings with low carbon dioxide concentrations. F. F. Blackman[4], who, in 1895, placed leaves under similar conditions in a gas stream, could not verify these observations. He concluded that "in bright light a fully green leaf assimilates all the carbon dioxide that it is forming by respiration and none escapes from it". This was the general conception up to 1947.

In this year Audus and Gabrielsen[6], independently of each other, published results which definitely contradicted those of Blackman. Audus performed his experiments in streaming air and exposed the leaves to electric light (intensities up to 3,000 candle-power, or approximately 35,000 lux). He found that the leaves could not re-assimilate more than about nine-tenths of the respiratory carbon dioxide, even at the highest light intensities. Gabrielsen enclosed his leaves in a six-litre flask, illuminated with 10,000 lux, and observed carbon dioxide evolution until a level of about 0·009 vol per cent was reached; these and other static experiments[7] suggest that the photosynthetic process necessitates a concentration of 0·009 vol. per cent carbon dioxide in the surroundings of the assimilation centres before they start working. The rate of carbon dioxide evolution was found to be almost identical for leaves held in light, or in the dark, so long as the carbon dioxide concentration around the illuminated leaves did not exceed 0·006 vol. per cent.

The re-assimilation problem has now been the subject of further studies. Leaves with a total area of 140–170 cm.^{2} were placed in a chamber (150 × 150 × 10 mm.) through which a steady current of carbon dioxide-free air was maintained. The liberated carbon dioxide was absorbed in 0·025 *N* barium hydroxide in a Boysen Jensen tube and measured for periods of 10–20 minutes duration. The temperature of the mesophyll was controlled by means of thermocouples and kept at the same level (± 0·2°) in dark and in illumination experiments.

The results of two typical experimental series (at 20° C. and a flow-rate of 14·8 ml. air/cm.^{2} min. in the leaf chamber) are given in the accompanying graph. Solid lines illustrate results of experiments with sun leaves of *Sambucus nigra* (leaf thickness about 0·23 mm., fresh weight per dm.^{2} 2·51 gm.); dotted lines indicate results of experiments with shade leaves of the same species (leaf thickness 0·13 mm., fresh weight per dm.^{2} 1·34 gm.). The different behaviour of the two kinds of leaves is obvious. In the



Output of carbon dioxide from leaves in light and in the dark. White part of the axis of abscissæ, illumination intensity of 10,000 lux; black part, dark experiments relatively thick sun leaves with a high rate of respiration, 56 per cent of the respiratory carbon dioxide is re-assimilated; in the thin shade leaves, in which the respiration-rate is less than one-fourth of that found for sun leaves, no photosynthesis occurs at all.

Further experiments with *Sambucus nigra* leaves and leaves of other species revealed the following facts: (1) The ratio of the re-assimilation-rate to that of respiration (Q_r) is highest in leaves with high respiration-rates. (2) A comparison of Q_r in thick and thin leaves with identical respiratory-rates shows that the highest values are found in the thick ones. (3) Experiments at different temperatures with one and the same batch of sun leaves show a diminishing of the Q_r values with decreasing rate of respiration. When this latter rate is lowered from 0·58 at 20° ($Q_r = 0{\cdot}41$) to 0·12 mgm. CO_2/dm.^{2} hr. at 5°, no photosynthesis is observed. (4) Re-assimilation begins in shade leaves when the respiration is elevated from 0·31 at 20° to 0·58 mgm. CO_2/dm.^{2} hr. at 30° ($Q_r = 0{\cdot}24$). (5) A variation of the flow-rate of the air in the leaf chamber does not affect the respiratory-rate but shows a marked influence upon the rate of photosynthesis. When the flow-rate is increased from 15·0 to 32·9 ml. air/cm.^{2} min. for sun leaves having a respiratory intensity of 0·62 mgm. CO_2/dm.^{2} hr., the value of Q_r is reduced from 0·50 to 0.

These findings demonstrate that the photosynthesis under the given conditions depends upon: (1) the rate at which carbon dioxide is produced in the leaf; and (2) the rate at which the carbon dioxide is transported from the leaf to its surroundings. If the respiration-rate is low, and/or the possibilities for carbon dioxide to escape are great, no photosynthesis takes place. It is obvious that photosynthesis only occurs when a certain amount of carbon dioxide is accumulated in the green cells. Thus the experiments bring further evidence for the theory of the existence of a threshold value for carbon dioxide concentration in photosynthesis of leaves. The results of the experiments with shade leaves, and the other experiments in which identical rates of carbon dioxide evolution are observed during dark and illumination periods, make it evident that the intermediate products of respiration are not re-utilized in photosynthesis.

A detailed report will appear in *Physiologia Plantarum*.

Nucleotide Content of the Nucleolus

THE plasmosome type of nucleolus is the only commonly observed intranuclear structure which clearly is not chromatin, from which the nucleolus is easily distinguished by the fact that it gives a negative Feulgen nucleal reaction for desoxypentose nucleic acid. Although it is thus evident that the nucleolus probably does not contain the characteristic polynucleotide of chromosomes, the shape of the ultra-violet absorption curve shows that there is considerable nucleotide of some type in the nucleolus[1]. The basophilia of the nucleolus is attributed to this nucleotide. It can be inferred that at least a part of the nucleolar nucleotide is ribonucleic acid from the fact that ribonuclease reduces the capacity of the nucleolus to bind basic dyes[2]; but this conclusion is open to the objection that the nuclease used was probably contaminated with some protease activity[3].

This communication reports the results of a quantitative study of the effects of chemical extraction[4] and digestion by protease-free ribonuclease[3] on the ultra-violet absorption of the large, homogeneous nucleoli which occur in early meiotic prophase nuclei of sporocytes of *Zea mays*[5]. Each absorption determination was made through a central cylindrical area of a whole nucleolus, in paraffin sections of material fixed in Carnoy's acetic alcohol, using a quartz microscope and suitable photometric apparatus[5]. In each of the three experiments the extraction or digestion caused approximately the same percentage reduction of the extinction (about 53 per cent), which shows that each time the same total mass of absorbing substance was removed from the nucleoli.

Effects of chemical and enzymatic removal of nucleotide from fixed nucleoli of sporocytes of *Zea mays*, measured by ultra-violet absorption

Treatment	Number of nucleoli	Mean E_{2537}	Reduction of extinction	Percentage reduction
		Experiment No. 1		
None	23	0·874±0·010		
Hot TrAc	10	0·407±0·009	0·467	53·4
		Experiment No. 2		
None	17	0·843±0·016		
Ribonuclease	17	0·395±0·010	0·448	52·8
		Experiment No. 3		
None	31	1·000±0·014*		
Cold TrAc	31	0·860±0·011	0·140	14·0
Hot TrAc	30	0·472±0·008	0·528	52·8

Abbreviations: E_{2537}, extinction at wave-length 2537 A.; TrAc, 5 per cent trichloracetic acid. * The higher extinction values of Experiment 3 are due to the fact that absorption was measured through a narrower central area of the nucleolus, with a correspondingly longer optical path

All nucleotides are soluble in hot 5 per cent trichloracetic acid[3], and therefore the amount of reduction of extinction caused by this treatment, Experiment 1 (0·467), is a measure of the *total nucleotide content of the nucleolus*. The residual light loss, or blank (0·407), is presumably due to specific protein absorption and to non-specific light reflexion and scattering[1,5]. All this nucleotide absorption is removable by ribonuclease digestion, Experiment 2, which shows that the *nucleolus contains only nucleotide of the ribose, or pentose, type*. Slightly more than one-fourth of the nucleotide is soluble in cold 5 per cent trichloracetic acid, indicating that this proportion is a *lower nucleotide polymer than nucleic acid*[3]. There is evidence that fixation in Carnoy's fluid[3] removes from cells practically all the common acid-soluble mononucleotides[6], which suggests that the cold acid-soluble nucleolar nucleotide which survives Carnoy fixation may be a polymer which is intermediate between mononucleotide and nucleic acid. One of the interesting possibilities raised by the presence of this smaller ribose polynucleotide is that the nucleolus may be a site of synthesis of ribonucleic acid.

Orientation of the Mitochondria during Mitosis

LITTLE is known concerning the behaviour of the mitochondria during cell division. Therefore we have studied the mitosis of cells from the tail of the pancreas in very young albino mice of the Danish State Serum Institute strain. The mice were three to eight days old (weight, 3–3½ gm.). For vital staining of the pancreatic cells the technique of Scott[1] was used. The carotids were clamped, a needle, wire gauge 26–27 (outer diameter, 0·5 mm.; inner diameter, 0·22 mm.), was introduced into the left ventricle of the heart, and Janus Green B solution 1/100,000 was injected at a pressure of 250–300 mm. mercury in the course of some fifteen minutes. The heart was contracting during the injection.

Half an hour before this procedure, 0·1 c.c. heparin solution (5 : 100) had been injected into the abdominal cavity.

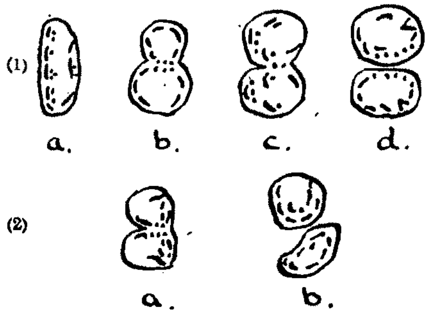
In 190 mice thus examined, only 51 mitoses were seen going on, including all phases of the division.

As soon as the injection has been finished, the pancreas was dissected out; this takes about five minutes, and a bit of the tail was pressed between a slide and a coverslip. The cells were observed at a magnification of 2,400 × (Zeiss, apochrom. *H I* 90, *K* 7 ×, binoc.) During the observation the preparation was kept at 20–22° C.

We tried to photograph the mitochondria, but did not obtain satisfactory pictures, possibly because proper film material was not at our disposal.

During all the phases of mitosis the mitochondria always move in such a manner that they are symmetrically arranged in relation to the plane of cleavage. This is seen from the drawings.

This finding is in accordance with the statistical observations reported by M. D. Thurlow[2,3], from whose work it seems probable that in mice all nerve cells contain the same number of mitochondria.



Mitochondria during mitosis: (1) Mitosis from prophase to telophase; (2) mitosis from anaphase to telophase

The symmetrical distribution of the mitochondria during mitosis indicates that they are of high importance to mitosis, and in their behaviour cannot but remind us of chromosomes during division.

Feeding and Reproduction in the Pyramidellids

THE mode of life and relationships of the Pyramidellidæ have remained more obscure than those of any other group of the gastropods, though such aberrations as the presence of a radula, the hermaphrodite gonad and their suspected parasitic habit have aroused comment[1,2]. Pelseneer[1] described the feeding of *Brachystomia rissoides* (Hanley) = *Odostomia scalaris* Macg., which is parasitic on *Mytilus*: several individuals congregate on the edge of the shell of the mussel and each protrudes a long proboscis which is fixed to the inner surface of the mantle. No further details are given.

A similar association has now been established between five other species of pyramidellids and other animals, and the feeding process observed. *Odostomia eulimoides* Hanley lives on scallops, *Pecten* and *Chlamys*; *O. lukisii* Jeff., *O. plicata* Mont. and *O. unidentata* Mont. lurk among colonies of *Pomatoceros*, *Serpula* and *Spirorbis*; *Chrysallida spiralis* Mont. on those of *Sabellaria* spp., while it is known that *Turbonilla rufescens* Forbes is associated with a cœlenterate as yet unidentified. When the opportunity occurs, these molluscs extend a long proboscis and attach it to the body of their host—to the mantle of a lamellibranch, the tentacle of *Pomatoceros*, or, in the case of *C. spiralis*, it is thrust through the mouth of *Sabellaria* and fastened to the wall of the gut.

The gut is extremely specialized in connexion with this mode of feeding. There is a long introvert lined by a specialized epithelium, and when this is protruded it is found that the mouth is surrounded by a sucker by means of which the proboscis is fastened to the body of the host. Above the mouth, in the centre of the sucker, lies a second opening from which projects a long, hollow stylet which represents the fused jaws. Both mouth and stylet lead to a long, narrow tube, the modified buccal cavity, divided into two channels: the ventral, from the mouth, leads to a muscular pump; the dorsal contains the stylet into which run the ducts from the salivary glands. The sucker secures the proboscis to the prey; the body is pierced by the stylet, saliva may be used to loosen the tissue, and fluid, with perhaps loosened cells, is then sucked in through the mouth by the pump. The œsophagus is a long capillary tube leading to a simple stomach, and a short rectum passes to a mantle cavity, which contains many simplifications similar to those described in *Omalogyra*[4].

Each species of pyramidellid seems to restrict its feeding to one host. Were we to know these, then it appears that the collection and study of this little-known group would be greatly simplified.

Specialization also extends to the reproductive system, and of particular interest is the method of copulation, for this appears to be effected by an invaginable tube which passes *through* the nerve ring ventral to the gut. The tube, together with its accompanying muscular pouch, is reminiscent of the copulatory apparatus of *Omalogyra*[4], which, however, is contained within the hermaphrodite duct and is not an independent structure. The eggs of *Odostomia* spp. are laid on their feeding grounds—on the shells of lamellibranchs or among the tubes of polychætes. A number of eggs are embedded in a copious supply of jelly[3] which binds them together and to the substratum, and which is produced by the hypertrophy of the upper part of the pallial oviduct during the female phase of these protandrous hermaphrodites.

The structure of the nervous system, gut and reproductive system may be shown to be consistent with the classification of the Pyramidellidæ as prosobranchs rather than opisthobranchs.

Cotton Crop Yield in Relation to Application of Fertilizers

IT is unfortunate that efforts to study the effect of various fertilizers on the cotton yield in Egypt have led to contradictory results. Thus Hughes[1], Prescott[2], and Khalil and co-workers[3] have reported that manuring has very little or no effect on the yield of cotton crop, while Mahmoud and Crowther[4,5,6], have shown that cotton produces better yield in response to nitrogen and phosphate applications, potash addition being without effect.

Several investigators[7,8,9] have found a correlation between the mineral composition of plant leaves, crop yield and fertilizer applications. We have carried out an experiment in which we have used foliar analysis of cotton (variety Menoufy) as an index to the nutrient conditions and crop yield of the plants. The soil plots that have been used in the present investigation are loamy in texture, situated in the farm of the Faculty of Agriculture, Fouad I University, at Giza, and have been under five controlled treatments since 1932. Each plot has seven replicates (9·20 × 8·20 m.) distributed according to the Latin square method.

The results seem to indicate that addition of any fertilizer gave better yield than that of plants grown in the completely unfertilized plots. It must be remembered, however, that the soil of the untreated plots has been without any fertilizer application since 1932; naturally such soil is rather spent. The plants that have been grown in plots supplied with full manure of phosphorus, potassium and nitrogen gave a higher yield than that obtained from plants given phosphorus and potassium but no nitrogen fertilizer. Non-addition of potassium or phosphorus fertilizer seems to have very little effect on the crop yield. The results have also shown that the Egyptian soil contains relatively large amounts of unavailable phosphorus and potassium, but little nitrogen; hence the need for addition of nitrogen fertilizer alone. We believe that the most suitable nitrogen fertilizer would be ammonium sulphate, because the ammonium–nitrogen will soon be transformed into nitrate by means of nitrifying and nitrating bacteria which are usually abundant in Egyptian soil fit for cultivation. In the meantime the sulphate ion will help to neutralize the alkalinity of the soil (the *p*H of the soil being usually about 8·0), and in doing so it renders available some of the naturally occurring unavailable phosphorus.

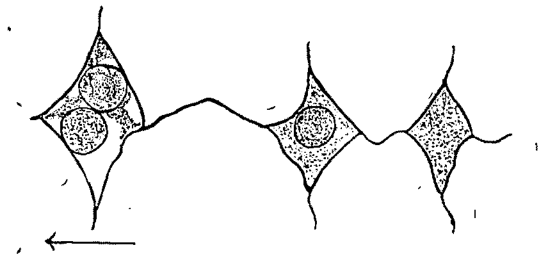
Intercellular Inclusions in White Mustard Roots Induced by Colchicine Treatment

DURING the course of an anatomical study of colchicine-induced hypertrophy in white mustard roots, attention has been given to some peculiar intercellular inclusions which are certainly not present in untreated roots. In this study, newly germinated seedlings are immersed in a 0·1 per cent colchicine solution for two hours, thoroughly washed in distilled water and then placed on moist filter paper to grow for a period of three days. At the end of this time, marked hypertrophy, characterized by stunted swollen root tips and an exceedingly dense development of root hairs, is obvious.

As already noted[1], rows of radially placed intercellular spaces occur at an early stage in the meristem of normal white mustard roots and are thought[2] to facilitate the more rapid movement of food materials to the surface cells. In hypertrophied root tips they are also conspicuous, but here they frequently contain a granular substance and spherical bodies which are comparable in size, stain reaction and general appearance to nuclei in adjacent cortical cells. Since the walls of the cortical cells forming the spaces are intact, the inclusions might be considered to be of the nature of tyloses or internal 'root hairs' growing from the cortical cells. Such an idea would fit in with the irregular swelling of the epidermal cells, marked increase in cellular volume of the cortex and the abnormal production of root hairs by the root



Drawing × 1,300, in cross-sectional view, of one row of radially arranged intercellular spaces in the cortex of a hypertrophied root, showing the intercellular inclusions. The arrow points to the outside of the root cap cells. If the inclusions are tyloses they should be surrounded by cell walls of their own. The presence of a cell wall is still under investigation; but, as soon as this has been decided, further data, including other abnormal features in these roots, will be published.

Liberation of *nor*Adrenaline from Adrenal Medulla by Splanchnic Stimulation

The active principle of the suprarenal medulla is commonly believed to be adrenaline. Holton[1] has recently shown, in this laboratory, that tumours of the medulla contain the non-methylated primary amine *nor*adrenaline in greater amount than adrenaline.

We have examined extracts of the suprarenal glands of dogs by determining the power of the extract to inhibit (*a*) the isolated rabbit intestine, and (*b*) the isolated rat uterus when stimulated by acetylcholine. The former test measures adrenaline plus *nor*adrenaline, the latter measures adrenaline only. We found that of five glands, two contained adrenaline only, while the active material in the other three was a mixture containing 14, 28 and 52 per cent *nor*adrenaline.

To find if *nor*adrenaline is actually liberated when the splanchnic nerve is stimulated, we have examined the effect of stimulating the splanchnic nerve in the cat. The experiments were carried out in spinal cats from which the viscera were removed and the kidneys excluded from the circulation. In these circumstances, splanchnic stimulation sent impulses to the suprarenal medulla only.

To distinguish between adrenaline and *nor*adrenaline, we used, in each experiment, the nictitating membranes of the same cat, one of which had been denervated not less than eight days previously by extirpation of the superior cervical ganglion. When an injection of adrenaline was made, the denervated membrane usually contracted more than the normal membrane, the mean value for the ratio of the size of the contractions being 1·6. When an injection of *nor*adrenaline was made, the ratio was, however, much greater, the mean value being 9·1. The ratios remained very nearly the same in any one experiment. When the splanchnic nerve was stimulated, the nictitating membranes contracted, and the ratio of the contractions indicated that the stimulation liberated a mixture of adrenaline and *nor*adrenaline. We were able to match the effect of splanchnic stimulation by the intravenous infusion of an equipressor mixture of adrenaline and *nor*adrenaline, and found that in different experiments the proportion of *nor*adrenaline varied from 20 (or less) to 80 per cent of the total active material secreted.

Central and Peripheral Mechanisms in the Increase of Metabolic Rate; Mode of Action of Thyroxine

It is sometimes difficult to decide whether an increase in metabolism is due to stimulation of the hypothalamic centres or to direct action on tissue respiration. Neither transection of the cervical spinal cord nor administration of barbiturates furnishes convincing evidence[1,2]. The former does not interfere with the nerve supply of the muscles of the head and the neck, nor with the connexions of the abdominal organs with the central nervous system through the vagi. Barbiturates may directly depress tissue respiration.

Morphine-scopolamine narcosis gives a more definite answer. This combination acts preferentially upon the hypothalamic centres without influencing tissue respiration. It does not decrease the basal metabolic rate of rabbits, nor does it affect the increase in the metabolic rate brought about by adrenaline or 2,4-dinitrophenol, the action of which is known to be peripheral[3,4]. On the other hand, it restores to normal values metabolic rates which have been increased by some central mechanism, as in the case of cooling the animal or administration of β-phenyl*iso*propylamine ('Benzedrine', 'Amphetamine').

If thyroxine is used to increase by 50 per cent the metabolic rate of rabbits, morphine-scopolamine has a depressing effect, although the rate cannot be restored to the normal value. Thus we conclude that, in the thyroxine effect on rabbits, a central as well as a peripheral mechanism is involved.

In birds, red blood-cells can be used for distinguishing between central and peripheral action upon metabolism. If the metabolism of ducks is raised by means of some action depending upon a central mechanism, such as cooling or subcutaneous administration of β-phenyl*iso*propylamine, there is no change in the oxygen consumption of these cells, which have no connexion with the nervous system, as measured on a suspension in the Warburg apparatus. On the other hand, adrenaline or dinitrophenol, administered subcutaneously, increases the *in vitro* respiration of the red cells. If we add blood plasma of an animal thus treated to a normal suspension of red cells, an increase in oxygen consumption of these cells ensues.

It has been found that after administration of thyroxine for four days, the respiration of the blood cells has increased to the same extent as the metabolic rate of the whole animal. Both effects fall off together. Blood plasma of a thyroxine-treated animal is unable to raise the oxygen consumption of a normal red blood-cell suspension. This may be explained by assuming that it takes some time for the thyroxine molecule to be built into the enzyme system of the cell. It is concluded that the metabolism-stimulating action of thyroxine in birds is entirely peripheral.

Detailed accounts of these investigations will appear elsewhere.

Tubular Factors in the Development of Extra-renal Azotæmia

It is well known that in the mechanism of extrarenal azotæmia the causative factor is the loss of sodium and subsequent dehydration[1]. According to Gömöri and co-workers[2], the causes of dehydration-azotæmia are as follows: (1) blood pressure falls, and in consequence of the dehydration the colloid-oncotic pressure of the blood plasma increases, thus resulting in a drop of the glomerular filtration-rate; (2) circulation is slowing down, contributing thus to the diminished filtration-rate; (3) excessive rotein catabolism helps to aggravate the uræmic condition.

Some clinical observations, and the fact that during dehydration the concentrating power of the kidneys decreases, led us to investigate the role of the tubules during this condition.

Dehydration was developed in rabbits, by Darrow and Yannet's technique[3], of infusion to, and subsequent withdrawal of, an isotonic dextrose solution from the peritoneal cavity. Our results show clearly that: (1) in dehydration there is a significant decrease of the endogenous creatinin clearance (glomerular filtration-rate), but a still greater decrease of the urea clearance; in the control period, the ratio urea clearance/creatinin clearance was 0·68–0·87, whereas during dehydration it was 0·07–0·20; (2) this must be due to enhanced tubular re-absorption of urea; normally 20–40 per cent of the filtered urea was re-absorbed, but during dehydration it was as much as 80–90 per cent.

Thus it seems to be beyond doubt that in the development of dehydration-azotæmia, besides the hæmodynamic glomerular factors, a tubular factor plays its part too. The cause of the increased re-absorption of urea may be found in various factors. The known diffusibility of urea renders it especially liable to passive re diffusion. But it seems to be certain that the histological changes in the kidneys of dehydrated animals (Gömöri and Romhányi's[4] findings of medullary hyperæmia and tubular lesions in dehydration) make the tubules especially suited for re-diffusion. These histological changes were found in our experiments also.

Period	Interval (min.)	Urine flow (ml./min.)	Creatinin		Urea clear.	Urea clear. / Creatinin clear.	Serum NPN (mgm. %)
			U/P	Clear.			
1	225	0·178	73	13·0	8·8	0·68*	26
2	524	0·136	33	4·5	1·8	0·40	40
3	1429	0·031	96	3·0	0·30	0·10	64
4	1964	0·045	16	0·7	0·07	0·10	90
5	2934	0·007	17	0·12	0·008	0·07	110
6	3390	0·091	12	1·1	0·22	0·20†	144
7	4319	0·131	19	2·5	0·45	0·18	164

* Before treatment. † Partial re-hydration with water.

In the table we give the results of one of our typical experiments. The ratio of urea to creatinin, expressing the tubular water re-absorption, emphasizes that the tubular re-absorption of urea is independent of the changes in water re-absorption, as well as being independent of the rate of urine flow.

Effects of a Serum Injection after an Anti Histaminic-Inhibited Shock

Pasteur, Vallery Radot, Halpen and Haltzer assert that an anti-histaminic-inhibited shock has n tachiphylactic action; more precisely, rabbits pro tected from a shock by an anti-hystaminic died o shock after another dose of serum was administere some days later. They considered the results as a argument in favour of their theory, namely, that anti histaminics prevent antigen-antibody reactions an thus leave the tissues free from antibodies to react with a subsequent dose of antigen. We have obtaine contrary results, however, in analogous experiments Thirteen guinea pigs have been sensitized wit 1/10 c.c. of horse serum by intraperitoneal injection. After fifteen days they were given 1 c.c. of the sam serum by intracardiac injection. Eleven were give 5 mgm. of an anti-histaminic ('Dimetina', kindly furnished by Le Petit Co.) by intraperitoneal injection 10 min. before the shock treatment. All o them survived, whereas the other two died.

These eleven guinea pigs were given next day another shock treatment with 1 c.c. of the same serum treatment by intracardiac injection. All of them survived. The weight of each guinea pig was about 300 gm.

Thus it seems that the anti-hystaminics do not inhibit the antigen-antibody reaction, and the latter disappears after an anti-histaminic-inhibited shock. This fact may be of considerable therapeutical value.

Folic Acid as an Anti-anaphylactic

Ten guinea pigs (of medium weight, 350 gm.) were sensitized with 1/10 c.c. of horse serum by intraperitoneal injection. After fifteen days, two of them, used as controls, were given 1 c.c. of the same sensitizing serum directly into the heart; both died. Another guinea pig was given, intramuscularly, 15 mgm. of folic acid ten minutes before receiving the same dose of serum by intracardiac injection. This guinea pig also died of anaphylactic shock. Six others were given 30 mgm. of folic acid by intraperitoneal injection (to accelerate absorption), and the same serum treatment fifteen minutes later. All of them survived. Finally, the last guinea pig was given 15 mgm. of folic acid intraperitoneally and the same serum treatment after fifteen minutes. This one survived, too, but showed slight symptoms of shock.

These experiments show clearly a protective action of folic acid against the anaphylactic shock in guinea pigs. This action reveals itself after a certain time and using very large doses of folic acid. Thus it may be supposed that folic acid acts in macrocytic anæmia as an anti-anaphylactic and thus antihistaminic. Assuming, as a pure hypothesis, that macrocytic anæmia may be due to an anaphylactic blockage of bone-marrow, especially as regards erythropoiesis, the successful results obtained with small doses of folic acid might be explained by a particular anti-anaphylactic action of this substance specific for normal erythropoiesis cells.

It may be remembered that agranulocytosis of Werner – Schultz, almost universally considered as a "condition caused by an anaphylactic crisis of bone-marrow" (Bock[1]), has been cured with massive doses of folic acid by Gendel, Black and Stanbury[2]. The more spectacular results obtained in the treatment of macrocytic anæmia can be explained supposing that folic acid has much more specific action on the allergic blockage of erythropoietic tissue than on the allergic blockage of the leukopoietic one.

Presence of Histamine in Central Nervous System Extracts

It is well known that alcoholic or aqueous extracts of central nervous tissues (especially brain) lower the arterial blood pressure when injected intravenously into laboratory animals (dogs, cats, rabbits, etc.)[1,2,3]. The chemical agent, or agents, of the pressor effect, however, have not yet been identified; studies by Vincent *et al.*[3], Major and Weber[1] and more recently Kwiatkowski[4] having apparently discarded (or greatly minimized) the role of both histamine and choline in the pharmacological activity of the extracts. The object of this note is to present evidence that histamine is the main agent responsible for the depressor effect, and that central nervous system tissues, therefore, as well as many other tissues (liver, lung, skin, muscle, etc.)[5], contain histamine.

	Histamine equivalent of the extracts (µgm./ml.)	gm. tissue / ml. extract	µgm. histamine / gm. tissue	Inhibition of the depressor responses by: benadryl (1 mgm./kgm.)	
					atropine (0·1 mgm./kgm.)
Extract *A* (0·09 ml.)	45	2·6	17·3	26 per cent	0 per cent
Extract *B* (0·125 ml.)	32	2·0	16·0	25 ,,	0 ,,
Equivalent histamine, 4 µgm.	—	—	—	24 ,, (3 mgm./kgm.)	—
Extract B_1 (0·23 ml.)	43	4·4	9·8	67 per cent	—
Equivalent histamine, 10 µgm.	—	—	—	71 ,,	—

To detect histamine in the extracts, we have used (as recently suggested by Loew *et al.*[6]) the new anti-histamine drug benadryl, which in the dog inhibits almost specifically the action of histamine on the arterial blood pressure, approaching the degree of specificity displayed by atropine against acetylcholine. Therefore we tested in *dogs* the action of both benadryl and atropine on the effect of the extracts, and found that benadryl reduced in the same degree the depressor responses both to the extracts and to small doses of histamine, whereas atropine (in agreement with the results of earlier workers[1,3]) left unmodified the depressor response to the former.

The accompanying table summarizes the results of a typical experiment, the extracts having been prepared from ox, sheep, dog or rabbit brain, as follows. The fresh nervous tissue was minced, mixed with twice its volume of 96 per cent ethanol and left (with frequent stirring) either at 20° or in the cold for 4–20 hours. The suspension was then pressed through a thin cloth, and the brain matter extracted once more in the same way. First and second filtrates were collected and evaporated *in vacuo* below 50°; the residue was spun off and the bulky precipitate of denatured proteins and lipids discarded (supernatant: extract *A*). Extract *B* (from ex. *A*) and extract B_1 are the same as extract *A* but treated with basic lead acetate until no more precipitate was formed, centrifuged to eliminate the precipitate, and the lead from the supernatant removed by precipitation with sulphate and centrifugation. After neutralization, the activity of the extracts was tested by injection into the femoral vein of dogs anæsthetized with pentobarbitone, blood-pressure records being taken from the carotid artery. The histamine equivalent of the extracts was determined by comparing the effect on the arterial blood pressure of different concentrations of extract with similarly different concentrations of histamine solutions.

Similar results are obtained with acetone or trichloroacetic[7] extracts of brain. Extractions of the nervous tissues with ethyl ether did not yield active preparations. The extracts, after purification with basic lead acetate, which does not remove the depressor activity (contrary to the findings of Major and Weber[1]) were further fractionated by following the main lines of the procedure described by Best *et al.*[8]. The activity was carried down in both precipitations with phosphotungstic acid and silver-barium hydroxide, the depressor effect of the active fractions, as well as that of the original extract, being inhibited by benadryl.

Full details of this work will be published elsewhere. We are indebted to Dr. J. J. Izquierdo for measuring the potency of some of our extracts.

Isolation from Acid-Fast Bacteria of a Growth-Factor for *Mycobacterium johnei* and of a Precursor of Phthiocol

Mycobacterium johnei will not grow on plain egg medium; but Twort and Ingraham[1] demonstrated that good growth could be ensured by the addition of acid-fast bacteria or products extracted from them with organic solvents. Egg medium containing 1 per cent dried *Myco. johnei* has been used for many years to cultivate the organism.

We have now isolated from *Myco. phlei* a compound capable of promoting vigorous growth of

Myco. johnei on egg medium. This new growth-factor has been obtained crystalline in the form of a colourless aluminium derivative, melting point 218° (found: C, 63·45; H, 7·9; Al, 3·0 per cent; figures for nitrogen were inaccurate owing to formation of aluminium nitride during combustion). The corresponding metal-free product has been isolated only as an amorphous powder of melting point 170° (found: C, 65·1; H, 8·55; N, 9·0 per cent; optical rotation, $(\alpha)_D^{23}$ $-16°$, $C = 3{\cdot}2$, chloroform). The absorption spectra in methanol show the following characteristics. Metal-free material: max. 250 and 310 mμ, $E^{1\,\%}_{1\,\text{cm}}$ 158 and 42. Aluminium derivative: max. 263 and 342 mμ, $E^{1\,\%}_{1\,\text{cm.}}$ 204 and 58. From the evidence available at present, we believe the approximate formula of the aluminium derivative of the factor to be $C_{49}H_{75}O_{10}N_6Al$.

Woolley and McCarter[2] reported that vitamin K concentrates, phthiocol (2-methyl, 3-hydroxy, 1-4 naphthoquinone) and other naphthoquinone derivatives promoted the growth of *Myco. johnei* on liquid medium, though these anti-hæmorrhagic compounds were less effective than cells of *Myco. phlei*, which they believed to supply some other factor also required for optimal growth.

We believe our growth-factor to be quite unrelated to the naphthoquinones, and using solid egg medium we have been unable to confirm the growth-promoting effect of phthiocol reported by Woolley and McCarter. Moreover, we have now isolated from *Myco. tuberculosis* a product resembling the known K vitamins, and have found that it also fails to promote the growth of *Myco. johnei*.

This compound has been isolated as a yellow oil which appears to be chromatographically homogeneous, but has yielded no crystalline derivative (found: C, 85·1, 85·15, 85·05; H, 10·1, 10·45, 10·25 per cent; molecular weight, cryoscopically in benzene, 688, 706, 691; refractive index $n_D^{25} = 1{\cdot}5286$; hydrogenation (Adams's catalyst) 316 c.c. hydrogen at N.T.P. absorbed per gm. The absorption spectrum in hexane is identical in shape and in the relative heights of the peaks with the spectra of vitamins K_1 and K_2, though the absolute height of the peaks is lower than either.

Quinone from *Myco. tuberculosis*		Vitamin K_2[3]	
max. (mμ)	$E^{1\,\%}_{1\,\text{cm.}}$	max. (mμ)	$E^{1\,\%}_{1\,\text{cm.}}$
242·5	227	243	287
248	241	249	305
260·5	220	260	275
269	216	270	275
325	41	325	53

The absorption coefficient is in agreement with the finding that this compound has a molecular weight greater than that of vitamin K_2 ($C_{41}H_{56}O_2$, mol. wt. 580), presumably due to the presence of a longer side-chain.

This oil yields phthiocol on alkaline hydrolysis, and appears to be the source of the phthiocol which was isolated from extracts of *Myco. tuberculosis* by Anderson and Newman[4]. The possibility that phthiocol might arise from vitamin K was first suggested by Fieser *et al.*[5]. We have failed to detect any free phthiocol in fresh extracts of *Myco. tuberculosis*, and a similar finding has been reported by Parschin[6]. Extracts which have been allowed to stand for some weeks are found to contain phthiocol, and this probably explains the observation of Crowder *et al.*[7], who reported the presence of both free and combined phthiocol in an unhydrolysed extract of *Myco. tuberculosis*.

Absolute Cross-sections for the Capture of Neutrons of 200 and 900 keV. Energy

KNOWLEDGE concerning compound nuclei can be derived mainly from two groups of experiments. The study of individual levels yields information as to the values that the total and partial widths can assume. Where in one nucleus several neighbouring levels can be observed separately, individual level distances can be determined. A great number of measurements of this second type have been made. They show that level-widths and -distances vary over a considerable range.

The distance between levels, however, becomes so small with increasing excitation energy that it would seem hopeless to derive all information only from observations of separated levels. But the observation of average values of widths and distances—particularly if known as a function of the excitation energy—can in this case be considered as a description of the compound nucleus as a whole.

Bethe and Placzek[1] have shown that the average cross-section for the capture of neutrons with zero angular momentum taken over many levels is

$$\bar{\sigma} = \frac{\lambda^2}{2\pi} \cdot \overline{\left(\frac{\Gamma_n}{D} \cdot \frac{\Gamma_r}{\Gamma_n + \Gamma_r}\right)},$$

where λ is the de Broglie wave-length of the neutron; Γ_r the radiation width; Γ_n the neutron width and D the level-distance. Γ_n/D is the sticking probability. For low neutron energies ($<$ 500,000 eV.) $\Gamma_n < \Gamma_r$, and therefore

$$\overline{\sigma_{\text{cap}}} = \frac{\lambda^2}{2\pi} \frac{\overline{\Gamma_n}}{D}.$$

Above 1 MeV., $\Gamma_r/(\Gamma_n + \Gamma_r)$ decreases rapidly with energy.

A number of theoretical attempts have been made to determine the value of $\frac{\Gamma_n}{D} \cdot \frac{\Gamma_r}{\Gamma_n + \Gamma_r}$. Qualitative considerations of Bohr's theory of the compound nucleus predict a continuous increase with increasing mass number. The quantitative theories of Bethe, Peierls and Kapur[2], and more recently Feshbach, Peaslee and Weisskopf[3], again show a monotonic increase of σ with mass number.

Determinations of $\overline{\sigma_{\text{cap}}}$ should be made with neutron sources with a spread in energy distributions which is small compared to the mean energy but big compared to $\overline{D}$, the mean level-distance, so that the experimental result is a mean over many levels. (This is, for example, the case for the photo-neutrons produced by radiothorium in heavy hydrogen ($E = 200 \pm 28$ keV.) and beryllium ($E = 900 \pm 13$ keV.), and also for D—D sources, with certain precautions as to target thickness and angular distribution.)

Measurements of this kind have already been made[4]. They all show that $\overline{\sigma_{\text{cap}}}$ does not vary monotonically with the mass of the compound nucleus formed by the capture of the neutrons. In these circumstances, it seemed desirable to repeat the measurements with all possible precautions, avoiding slowing down of neutrons in the source and by the surroundings and also taking into account new data obtained for the absorption coefficients of β-rays.

The capture cross-sections of the elements for 900-keV. neutrons were measured in the following way. The cross-section for manganese was determined absolutely by irradiating a manganese sulphate solution with a radiothorium–beryllium photo-source, under conditions in which it is possible to calculate the fraction of all neutrons captured by the manganese. The radioactive manganese is precipitated from part of the solution and its β-activity measured on a Geiger–Müller counter. The same precipitated powder is then irradiated by the photo-source in air, and its β-activity again measured. The absolute cross-section of neutron capture can be calculated directly from the ratio of the two counts and the ratio of capture cross-section of manganese to hydrogen for thermal neutrons; it is not necessary to know the absolute neutron flux or the β-counting efficiency of the Geiger–Müller counter.

The cross-sections for the other elements were then determined by measuring the ratio of their β-activities to that of the manganese when irradiated by the photo-source in air, and also the ratio of the self-absorption of their β-rays to the β-rays of manganese. The cross-sections for 200-keV. neutrons were obtained directly by using these results in conjunction with those of Allen and others[5], who found the ratio of the cross-sections for 900 and 200-keV. neutrons. The results are given in the accompanying table.

Isotopic cross-sections (millibarns)

	$^{28}Al_{13}$	$^{56}Mn_{25}$	$^{64}Cu_{29}$	$^{76}As_{33}$	$^{107,109}Pd_{46}$
σ 900	2·05 ± 0·7	7·2 ± 0·7	8·8 ± 1·8	81 ± 7	214 ± 60
σ 200	3·5 ± 1·4	15·6 ± 4	11·4 ± 3	300 + 40	430 ± 140

	$^{111}Pd_{46}$	$^{108}Ag_{47}$	$^{116}In_{49}$	$^{122}Sb_{51}$	$^{128}I_{53}$
σ 900	131 ± 50	370 ± 70	650 ± 110	156 ± 80	180 ± 30
σ 200	146 ± 70	740 ± 160	525 ± 120 54 min.	185 ± 50	300 ± 60

	$^{139}Ba_{56}$	$^{131}Te_{52}$	$^{187}W_{74}$	$^{199}Pt_{78}$	$^{198}Au_{79}$
σ 900	4·3 ± 2	26·5 ± 8	42 ± 7	480±230	490 ± 80
σ 200	8·1 ± 4·3	34 ± 17	60·5 ± 19	1170±600	490 ± 120

Clearly the cross-sections of nuclei of comparable mass number show considerable differences. This is most striking for antimony, tellurium, iodine and barium. Very low cross-sections for bismuth and lead[2] have been found by other authors. It is also obvious that the general tendency of the cross-sections to increase with increasing mass number is not very marked.

It was pointed out by Halban and Kowarski[4] that these selectivities might be due to the strong dependence of $\overline{\sigma_{\text{cap}}}$ on the binding energy, which is known to vary between 6·5 and 10 MeV. in the case of the formation of active nuclei. It is, of course, true that the comparisons of different nuclei would be of more significance if they could be made for constant excitation energy (that is, binding energy + kinetic energy of the captured neutron). It would, however, be experimentally very difficult to compensate the great differences in binding energy by using neutrons of different energy. In any event, such comparisons are not very significant, as with increasing neutron energy, other effects, such as inelastic scattering of neutrons, *n*—2*n* reactions, as well as the contributions of neutrons of high angular momentum, become important.

In the meantime, however, a number of binding energies have become known through the determination of the energy liberated in (*d,p*) reactions. Although they do not yet give information about nuclei heavier than arsenic, they show that no direct link between binding energy and $\overline{\sigma_{\text{cap}}}$ can be established. A similar impression is conveyed by the results of Allen and others[5], who determined the ratio of $\overline{\sigma_{\text{cap}}}$ for neutrons of 900–220 keV. for twenty-three elements.

There seems, therefore, little doubt that we are faced with a contradiction between existing qualitative and quantitative theories on one hand, and experimental facts on the other. While it might be argued that there are only a few nuclei which show these marked deviations from the general trend of $\overline{\sigma_{\text{cap}}}$, existing theories do not allow for such variations.

Particles with Spin and the Principle of Reciprocity

Following a suggestion of Prof. Max Born and Dr. H. S. Green, we have extended their theory of ultimate particles, recently published in *Nature*[1], to the case of spin ½.

The metric operator, which in the case of spin 0 or 1 was $S = x^k x_k + p^k p_k$, is now

$$S = (p^k + i\gamma x^k)\alpha_k, \tag{1}$$

where α_k ($k = 1, 2, 3, 4$) is a set of Dirac matrices and $\gamma = \alpha_1\alpha_2\alpha_3\alpha_4$. Its reciprocal property is expressed by the equation

$$S(x_k, p_k) = T^{-1} S(p_k, -x_k)T, \tag{2}$$

where $T = \frac{1+i\gamma}{\sqrt{1+i}}$, and one obtains all self-reciprocal functions as solutions of the equation

$$S\mathbf{F} = \mathbf{F}s, \tag{3}$$

where s is an eigen-symbol depending only on γ.

These solutions can again be expressed in terms of Laguerre polynomials $L_n{}^k(P)$, where $P = p_k p$;^{k} it is convenient to write them separately for the two eigen-values ± 1 of γ, namely,

$$\mathbf{F}_1 = 2\{(\alpha_r p^r)\,L_n{}^{k+2}(P) \pm \sqrt{n-k-1}\,L_n{}^{k+1}(P)\}\,(\alpha_r p^r)^k e^{-P/2} g, \tag{4}$$

$$\mathbf{F}_2 = 2\{(\alpha_r p^r)\,[L_n{}^{k+1}(P) - L_n{}^{k+2}(P)] \pm \sqrt{n+1}\,L_n{}^{k+1}(P)\}\,(\alpha_r p^r)^k e^{-P/2} g, \tag{5}$$

where g is a three-dimensional spherical function depending on the direction of the 4-vector p_r; n has the values 1, 2, 3, . . ., while $k = 0, 1, 2, \ldots n - 1$.

The roots of the equations $\mathbf{F}_1 = 0$, $\mathbf{F}_2 = 0$ are as before, the mass factors $\varkappa^2$ from which the real masses are obtained:

$$\mu = \frac{\hbar\varkappa}{ca}, \quad \text{and with } a = \frac{e^2}{mc^2}$$

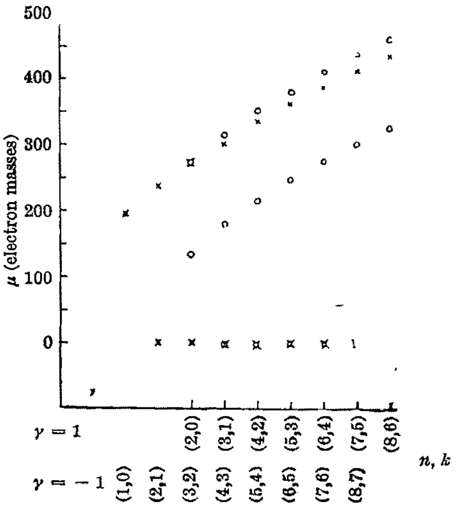
one has $\dfrac{\mu}{m} = \dfrac{\hbar c}{e^2}\,\varkappa = 137\varkappa$. Following Born and Green, we shall regard m as the mass of the electron.

As the expressions (4) and (5) have both the factor $(\alpha_r p^r)^k$, it follows that for odd $k > 1$ the theory predicts the existence of neutrinos satisfying

$$\alpha_r p^r = 0. \tag{6}$$

As already said in the previous communications, it seems to be very likely that the same factor represents electrons as charged neutrinos, the finite mass of which is due to the self-energy of the electromagnetic field produced by the charge. A preliminary proof of this has been given by Dr. Green.

For even k, one has particles satisfying the same equation as photons, $(\alpha_r p^r)^2 = p_r p^r = P = 0$, but with different spin properties.



Then there are a great many other particles, mesons with spin ½, the masses of which are obtained by putting the brackets in the expressions (4) and (5) equal to zero and solving for P. The values of $\varkappa$ for these are given in the accompanying table, and the rest-masses represented in the diagram.

Thermal Conductivity of Superconductors

MEASUREMENTS have recently been made in this Laboratory of the specific thermal conductivity at liquid helium temperatures of a series of tin specimens, ranging from spectroscopically pure tin to alloys containing up to 4 per cent of mercury. A tantalum specimen was also measured. The apparatus was based upon the design of de Haas and Rademakers[1], with a pair of gas thermometers measuring the temperature at two points on a rod carrying a known heat power. An innovation was the use of the thermometers differentially, the pressure difference being indicated on a butyl phthalate oil manometer read with a travelling microscope. A much finer resolution was possible than in previous work[1,2], thus enabling accurate measurements of thermal conductivity to be made with temperature differences of only 0·01° K. Consequently a careful survey could be made of the

(The experimental points are omitted from curves B, C and D, the scatter being of the same order as for Sn2 and Sn3)

region close to the superconducting transition temperature. The thermal conductivity was measured in both superconducting and normal state, the latter by destroying superconductivity with a longitudinal magnetic field. In the case of very pure tin, the magnetic field produced a large variation of conductivity in the normal state, and extrapolation was necessary to derive the value in zero field.

Typical conductivity-temperature curves are shown in Fig. 1 for spectroscopically pure tin (Sn2) and tin containing 0·033 per cent of added mercury (Sn3). According to Makinson[3], the electronic thermal resistance of a pure metal may be expressed as the sum of lattice vibration scattering and impurity scattering terms, $\alpha T^2 + (\beta/T)$, and this formula was found to represent the results for the normal state quite well. The initial slope of the conductivity curves gave values of β in good agreement with the theoretically predicted values ρ_0/L_0, where ρ_0 is the residual electrical resistance and L_0 the Lorenz number.

The ratio of superconducting to normal conductivity is plotted in Fig. 2 as a function of the reduced temperature T/T_c, where T_c is the transition temperature. No discontinuity is apparent in the curve or its gradient at the transition point, but the values of K_s/K_n for Sn2 and Sn3 fall on a single curve, in spite of the very large difference in the absolute values of their conductivities; this suggests that the ratio may be a characteristic function of temperature. It is interesting to note that a universal function of this kind proposed by Heisenberg[4] and shown dotted in Fig. 2 is in fair agreement with the experimental data.

On the basis of this concept, the departures for the less pure specimens Sn6 and Sn9 from the curve for Sn2 and Sn3 may be interpreted as due to the additional heat transport through the ionic lattice itself, which may reasonably be assumed to be independent of whether the metal is superconducting or normal. This additional contribution would naturally become important for specimens in which the low purity gives rise to a low electronic conductivity; on the assumption that the ratio of the superconducting to normal electronic conductivities is given by the Sn2 and Sn3 curve, a new method of estimating the lattice conductivity is provided, the values so obtained for Sn6 and Sn9 being consistent and of a reasonable order of magnitude.

The tantalum specimen shows the same general behaviour as tin, but the curve of K_s/K_n departs somewhat from the curve for pure tin. If, as suggested above, there is a universal curve for K_s/K_n as a function of reduced temperature which applies to all superconductors, the difference between the tantalum and pure tin curves can probably be attributed, as in Sn6 and Sn9, to heat transfer by the lattice itself.

The K_s/K_n curve for lead[1] is also shown in Fig. 2 and does not contradict the idea of a universal ratio curve if this is assumed to apply only to impurity scattering (responsible for the β/T term in Makinson's expression for the normal conductivity). Comparison of Makinson's formula with the normal curve for lead indicates that lattice vibration scattering (responsible for the αT^2 term) is predominant except at the lowest temperatures. The abnormally low values of K_s/K_n at higher temperatures may perhaps be interpreted as indicating that scattering of electrons by lattice vibrations is much more effective in the superconducting than in the normal state. The K_s/K_n values for lead are roughly in agreement with the Heisenberg curve at the lowest temperatures where impurity scattering is the main process.

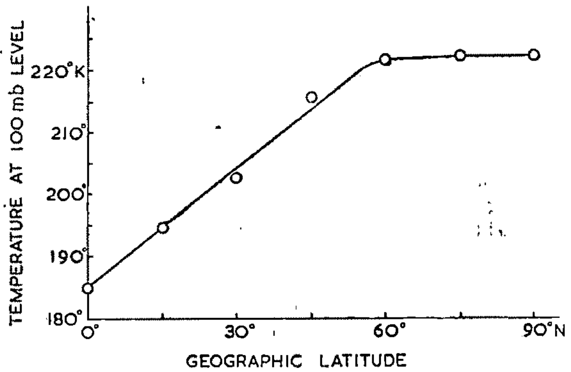
Latitude Effect and Pressure-Level of Meson Formation

Kupferberg[1] first, and later on Rathgeber[2], have both directed attention to the possibility that the latitude effect of cosmic rays due to the geomagnetic field may be partially masked by the fact that the height of the pressure-level of meson formation increases towards the equator. In particular, Rathgeber has shown, by taking 100 mb. for this pressure-level, that owing to this increase, the intensity of mesons at sea-level at mean latitudes should exceed the intensity at the equator by 3 per cent. The magnetic latitude effect would therefore be reduced from 10 to 7 per cent.

I wish to point out that a further correction must be applied as a consequence of the increase with latitude of the temperature at the level of meson production. I reported at the Bristol Symposium on Cosmic Radiation last September that the temperature at this level, or its equivalent the density, appears to be a factor closely controlling the meson intensity at sea-level. The intensity at sea-level increases with increasing temperature or decreasing density at the rate of 0·11 per cent per ° C., that is, at the rate of about $-0\cdot22$ per cent for a change of air density at the region of production of $1\cdot0$ per cent. Further measurements made in the last two months have entirely confirmed the reality of this result. A detailed account of this will appear elsewhere. Since the temperature at the 100 mb.-level increases with latitude, we may expect, therefore, a greater intensity at sea-level of μ-mesons in mean latitudes than in the equatorial region. The accompanying figure gives the annual mean temperature of the 100 mb.-level, as obtained from the vertical distribution of temperature in summer and winter, according to Haurwitz and Austin[3]. It will be seen that the difference in temperature between the plateau above lat. 60° and the value at the equator amounts to about 36° K. This difference, multiplied by the coefficient $0\cdot11$ per cent given above, leads us to expect that the intensity of mesons would increase from the equator to latitude 60° by 4 per cent. Allowing for this increase, as well as that obtained by Rathgeber, the magnetic latitude effect would, therefore, be reduced to the small value of 3 per cent.



We may note, however, that in making these corrections it has been assumed that the mesons are formed at the same pressure-level in all latitudes. This seems to be the general belief, but it has not yet been proved. Indirect evidence that the bulk of the penetrating component is formed in the proximity of the 100 mb.-level in mean latitudes has been given[4], but no evidence exists, so far as we know, that this is so in the equatorial region. On the other hand, if mesons are produced by primary protons, it is plausible to expect that the region of production lies at greater depths at the equator, since the incident proton will have a greater energy at the equator and so may penetrate deeper into the atmosphere than those at higher latitudes, which will be of lower energy.

If, therefore, we assume that the mesons are formed at a pressure-level lower than 100 mb. near the equator, it may be seen that the atmospheric effects under consideration would result in the two corrections being opposite in sign.

Let us assume, for example, that the production-level at the equator is at 125 mb. From meteorological observations, the mean height of this pressure-level appears to be $15\cdot1$ km., while that of 100 mb. at lat. 45° is $16\cdot1$ km. Neglecting the change in energy spectrum, the difference in intensity due to decay of ordinary mesons would be given with sufficient approximation by the ratio of the difference in height to the mean range L. Thus, with the value $18\cdot6$ km. formerly found for L; $I_{45°} - I_{\text{Eq.}} = (15\cdot1 - 16\cdot1)/18\cdot6 = -5\cdot4$ per cent.

To estimate the effect of density, we will take the temperature at 125 mb. at the equator to be 196° K., and that at 100 mb. at lat. 45° to be 215° K. The relative densities at the two levels will be proportional to the pressure divided by the temperature, and so will be proportional to $100/215 = 0\cdot465$ and $125/196 = 0\cdot638$. The relative difference in density expressed as a percentage of the mean will be $200\ (0\cdot465 - 0\cdot638)/(0\cdot465 + 0\cdot638) = -31\cdot4$ per cent. With the density coefficient $-0\cdot22$ per cent per 1 per cent of density given above, we should have on account of this effect $I_{45°} - I_{\text{Eq.}} = +6\cdot9$ per cent.

The two atmospheric effects taken together would give $I_{45°} - I_{\text{Eq.}} = -5\cdot4$ per cent $+ 6\cdot9$ per cent $= +1\cdot5$ per cent.

Had we assumed 150 mb. for the production-level in the equatorial region and so a height of $14\cdot2$ km. and a temperature of 205° K., the sum of the two effects would have given $I_{45°} - I_{\text{Eq}} = -10\cdot2$ per cent $+ 9\cdot8$ per cent $= -0\cdot4$ per cent.

It may well happen, therefore, that the latitude effect as observed at sea-level is almost entirely due to the deflecting action of the geomagnetic field, owing to the accidental cancelling of the corrections due to the height and to the temperature of the production level. It will only be possible, however, to determine accurately the magnetic latitude effect when the variation of the height of the level of formation with latitude has been determined.

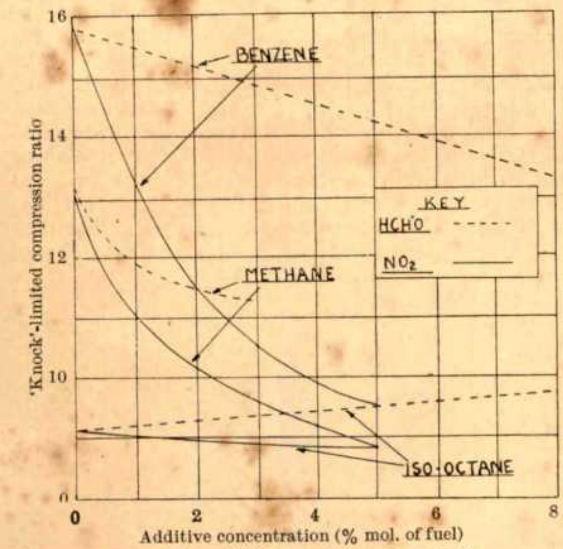
'Knock' in Internal Combustion Engines

WORK on the effect of additives on the 'knock'-limited compression ratios of a wide variety of fuels has shown that there are at least two mechanisms whereby a fuel may 'knock'. One appears to correspond to the 'high'- and one to the 'low'-temperature ignition process discovered[1] and thoroughly explored[2] by Townend and his co-workers. Hydrocarbons such as benzene and methane, which Townend did not observe to give a 'low'-temperature ignition peninsula, 'knock' by the 'high'-temperature process, and other hydrocarbons 'knock' by the 'low'-temperature process.

Using a Ricardo E.6 variable-compression engine, we have obtained curves of 'knock'-limited compression ratio (determined aurally) against concentration of additive. In the course of work with a very large number of additives (the full results of which will be published elsewhere) we have found that in benzene and methane, formaldehyde and nitrogen peroxide are strong pro-knocks, whereas in *iso*-octane, formaldehyde is an anti-knock and nitrogen peroxide has only a very slight pro-knock effect (see diagram). The differential effects of these dopes in the two classes of hydrocarbon correlate well with their effect on the 'high'- and 'low'-temperature modes of oxidation respectively[3,4]. The effect of these additives in hydrogen is similar to their effect in benzene and methane.



Tests on formaldehyde and nitrogen peroxide

In addition, we have found that both methane and hydrogen have considerable lead responses. The latter result differs from that of Egerton, Smith and Ubbelohde[5], who found tetraethyl lead to have no effect in hydrogen. It may be that the results of Egerton *et al.* were complicated by the incidence of pre-ignition, which is difficult to exclude when working with hydrogen.

This work was carried out in the Ricardo Laboratory on behalf of the Shell Petroleum Co.

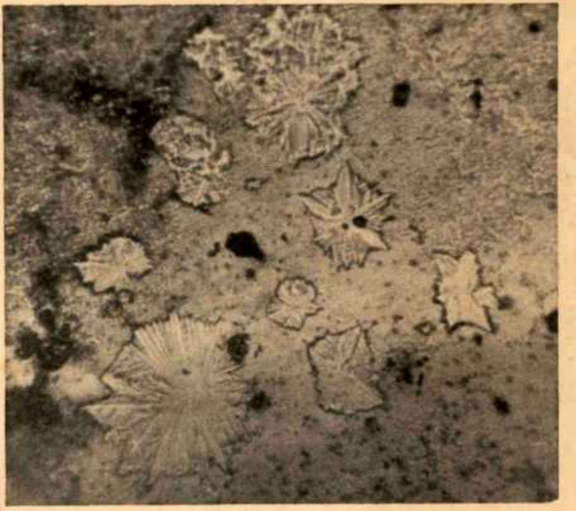
Hydrolysis of Starch Grains by Polarized Infra-Red Radiation

AT the Liverpool meeting of the British Association in 1923, it was shown that polarized radiation had the effect of accelerating the change of starch grains, in a *weak* suspension of diastase and at ordinary laboratory temperature, into a crystalline reducing substance; but if the diastase were active or concentrated, no *selective* effect was observed[1]. Earlier experiments in 1922 had shown me that, when ground cereals in plain tap water were exposed to this radiation, a portion of the starch was turned to sugar. This was estimated by Bertrand's method[2]. To meet criticism that the effect might be due to the pressure of the cover glass, the experiment was repeated; but instead of using a microscope slide, the starch suspension was in a flat-bottomed, very thin-walled flask, the base of which was irradiated by light, polarized and reflected vertically upward by a suspension of diastase in an *outer* vessel[3].

The resulting hydrolysis was so remarkable that, not only did it dispose of the cover-glass theory, but also it suggested that the polarization of the incident radiant energy by the diastase was the important *physical* factor in enzymatic hydrolysing action; for the enzyme was not in contact with the substrate.

Hydrolysis without enzyme. Prof. E. C. C. Baly pointed out to me that the absorption bands, both of water and the carbohydrate groups, were in the short infra-red. Fused silica ('Vitreosil') dishes, which transmit these rays, have now been used. Radiation from an electric spiral or small radiator was reflected by black glass or by ferrotype at the polarizing angle, striking the underside of the dish containing a suspension of well-washed potato-starch grains. After a period of about seven hours, the grains in some places had a dull, swollen appearance. On drying, clusters of crystals were seen exuding from the grains, or totally escaped into the surrounding medium (see photograph). The temperature was usually only one, or sometimes two, degrees above the room temperature (generally about 19° C.).



The addition in later experiments of a trace of sodium chloride (0–0·3 per cent) greatly increased the effect. In this case, the crystals often formed *within* the grain, the coat of the grain gradually disappearing. The sodium chloride apparently acted as a co-enzyme.

The contents of the dish were washed out with distilled water, and, when tested in the usual way, gave evidence of sucrose.

If the experiment is done during the months when the potato tubers are in a dormant condition, the control, placed by the side with ordinary radiation, gives intact starch grains; but after February some crystals may be found and a few of the grains will be seen breaking.

The similarity of the results, though in a much smaller degree, indicates that in this experiment we are imitating the natural process of enzyme hydrolysis.

RADAR OBSERVATION OF HEAVY RAIN

By H. WHALLEY and G. J. SCOLES
Research Department, Metropolitan-Vickers Electrical Co., Ltd., Manchester

WHILE a certain amount of data on radar observations of tropical rain has been published, the accompanying photographs of a radar P.P.I. screen showing a belt of heavy rain passing over the Manchester district may be of interest. The wavelength used was 3 cm. and the pulse length 1 microsecond, the photographs being taken on the afternoon of Friday, November 19, 1948, approximate times only being given.

Fig. 1 is a tracing of the P.P.I. picture with the coast-line and certain known points plotted by range and bearing for identification purposes. The radius of the display is about 40 miles.

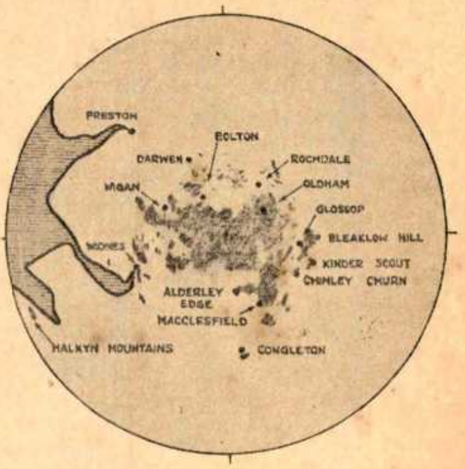

Fig. 1

Fig. 2 is a photograph, taken at 2.50 p.m., showing a belt of rain more than 30 miles long forming in the west.

Fig. 3 was taken at 3.30 p.m. Note how the rain is moving to the east, giving very strong echoes, the belt being continuous for more than 50 miles. Although not very obvious in the photograph, the centre of this belt is curved backwards, presumably being delayed by the high ground in the Wigan area.

Fig. 4 was taken at 4.20 p.m. The rain belt has passed over Manchester and is much shorter. Note the secondary belt of rain following the main one, and the apparent attenuation of the normally strong echo from the hill (Mow Cop) just south of Congleton, possibly due to the two rain belts across this path.

Fig. 5 was taken at 4.35. The belt has lengthened slightly and the centre is again delayed, possibly due to the high land in the Peak District. A further photograph was taken at 4.45 p.m., which showed that the rain had passed the Peak and appeared to be weaker; this may be due to the masking effect of the hills as the rain passes below the horizon.

The general speckled background in most of the photographs is the effect of receiver noise in the radar system.

The echoes received are from very heavy rain. The observed belt arrived in Manchester a little before 4 p.m. and was preceded by about five miles of light rain. At this period, Ringway Airport reported that 4 mm. of rain fell in 35 minutes. Light rain persisted for more than an hour after the heavy rain passed over.

UNIVERSITY TRAINING OF ZOOLOGISTS

AT a recent meeting in the rooms of the Zoological Society of London, the Association of British Zoologists held a discussion on the training of zoologists in the university, giving an opportunity to discuss the address which its president, Prof. H. Graham Cannon, had delivered when presiding over Section D of the British Association at Brighton last September. A large attendance of members pointed to the interest which this subject clearly has for zoologists at the present time.

The discussion was begun by Prof. D. M. S. Watson, who outlined the historical development of courses of zoology in London since they were first begun by Grant at University College in 1828. During the second half of last century, there took place the gradual establishment of the 'type' system, largely due to the work of Huxley at the Royal School of Mines and the Normal School of Science, and to that of Ray Lankester at University College; and this has survived to the present day as the basic plan upon which courses for degrees in zoology are built. As Prof. Cannon had pointed out in his address at Brighton, there was in the nineteen-twenties a general revolt against the dominating position of comparative anatomy in zoological education, and Prof. A. C. Hardy illustrated from the arrangement of courses in the Department of Zoology at Oxford how much time had now to be devoted to other parts of the subject. During the period 1943–45, 71 per cent of the lectures were allotted to a systematic treatment of the various groups of the animal kingdom, and the remaining 29 per cent to such general topics as ecology and the distribution of animals, genetics, evolution, physiology, embryology, cytology and histology. For the years 1946–48, the figures were markedly different—45 per cent only of lectures were devoted to a morphological treatment of groups; another 45 per cent to the general topics mentioned above, while the remaining 10 per cent went to a course on the history of zoology and to discussion of research topics, a weekly debate on controversial subjects. It seems doubtful, he said, whether the treatment of groups can be profitably or desirably reduced from this, as an understanding of their anatomy and relationships is necessary for the proper treatment of the more general part of the course.

Prof. Hardy emphasized that a course on zoology such as this is essential for the training of professional zoologists: for the general education of the university student reading other subjects, he was prepared to agree with Prof. S. Mangham, who addressed the Association on the recent memorandum prepared by the Association of Scientific Workers on the teaching of biology in universities. This memorandum proposes what is, in effect, the disappearance of separate university departments and courses of botany and zoology, and their replacement by a single integrated department and course of biology, on the ground that world conditions emphasize the need for a new approach to social and food problems, and that this could be well achieved through biology. A biological training, too, would produce not only good technicians but also good citizens, and so could well become a regular part of the curriculum for arts as well as for all kinds of science degrees. So far as the content of the courses was concerned, there was suggested the same kind of distribution of emphasis as indicated by Prof. Hardy (and which later discussion showed was, in fact, general throughout the universities)—a reduction in the teaching of evolutionary morphology, the time thus gained being used to give a more generous treatment of ecology, genetics, physiology, parasitology, human biology and the history of science.

Mr. H. W. Parker, speaking on the needs of the museums, emphasized that they require *educated* zoologists. The fields of knowledge needed in a museum zoologist's career would appear to be essentially compatible with a good general education, and no radical changes in the present zoological courses are called for, though changes of emphasis and timing might be beneficial. For example, natural history, being ill suited to laboratory methods, receives insufficient attention, and taxonomy is out of fashion now that the pertinent question is "How does evolution take place?" rather than "Has it taken place?" Yet, although geneticists and others may show how evolution can take place, the taxonomist can show how it has done so, or is doing so now. Greater taxonomic training would also lead to greater appreciation of the vast range and complexity of animate Nature, a matter which the 'type' system under-emphasizes. Museums must obtain recruits with knowledge suitable for developing new lines of attack: the scant attention by taxonomists to myology, compared with osteology, Mr. Parker said, reflects the different emphases on these two subjects in the universities, and the preponderant attention to marine zoology in most courses has repercussions in the museums. For the proper understanding of the relationships of recent animals, knowledge of the environmental conditions of the immediate past is essential, and this calls for acquaintanceship with geophysics and climatology. Finally, since abiding interests develop more readily in familiar than in unfamiliar fields, Mr. Parker pressed for greater collaboration and for the encouragement of students to visit and actually work in the museums.

RELATION OF A CLOVER JUICE FACTOR CAUSING PARALYSIS OF SMOOTH MUSCLE TO BLOAT IN RUMINANTS

By DR. W. CHARLES EVANS
AND
E. T. REES EVANS
Department of Animal Health, University College of Wales, Aberystwyth

FERGUSON[1] observed that whereas the juices of the most prevalent pasture grasses in Great Britain had little effect on the isolated rabbit intestine, those from certain legumes (for example, clover, lucerne) caused relaxation and paralysis. He excluded the possibility of certain inorganic ions, protein and alkaloid components from being responsible for this phenomenon. The importance of this finding in problems associated with the 'pasture-grazing animal' interrelationships is apparent.

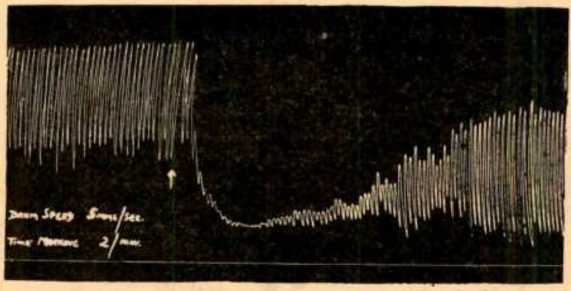

Fig. 1. Typical tracing of rabbit intestine treated with clover juice (2 ml. added to the Tyrode bath of capacity 50 ml.). Similar results obtained with known cytochrome poisons, see text

The cause of bloat, fog-fever, and ruminal atony in cattle and sheep, together with tympanitic colic and grass-sickness in horses, has not yet been established, although a particular pasture environment is usually incriminated. In bloat[2], it is believed that there is an inhibition of the eructation reflex associated with ruminal stasis; the animal being unable to belch, cannot void the gases produced in the paunch as a result of fermentation.

Working with the leaf juice of a white clover, we have shown that one of the factors responsible for the effect on the rabbit intestine is hydrocyanic acid. The evidence leading to this conclusion is as follows:

(1) The principle is absent from the residue of either the intact leaves or crude juice after drying at 100° C. in a well-ventilated oven.

(2) Separation of the crude juice into acid, neutral and basic fractions shows that the activity is concentrated in the ether-soluble acid fraction.

(3) Acidified clover juice was steam-distilled, and the distillate collected into ice-cold alkaline Tyrode solution. The distillate possessed the whole of the activity of the juice when tested on the rabbit intestine. It also gave all the chemical tests for a weak solution of hydrocyanic acid. The same acidified clover juice, treated similarly with respect to temperature, in a sealed tube, showed comparable activity with the original, after cooling and neutralization, but in an open tube had lost all activity. This illustrates the volatility of the factor, which caused erratic results in its concentration, until steps were taken to counter it.

(4) Crude clover juice, and a solution of hydrocyanic acid of the same CN′ concentration (estimated by the method of van der Walt[3]), produced almost identical responses on the isolated rabbit intestine (Fig. 1).

Several substances, both synthetic and of natural origin, were tried for their action on the isolated rabbit intestine; the well-known poisons of the cytochrome system all produce a response similar to that shown in Fig. 1, namely, for small doses, relaxation, and diminution of amplitude, with subsequent recovery, but with increased dosage, irreversible paralysis in the relaxed state. The necessary concentrations differ widely: for example, sodium cyanide (1/100,000); sodium sulphide (1/2,000); sodium azide (1/2,000). Hydroxylamine (1/5,000) has a similar effect. Hydrotropic substances like sodium desoxycholate, and sodium taurocholate (1/5,000) and surface-wetting agents (for example, the detergents 'Cetavlon', 'Teepol'). also possess a well-marked relaxing effect leading in some cases to paralysis. Saponin (1/5,000) paralyses the rabbit intestine in the contracted state.

It is known that some pasture plants, especially legumes, may contain cyanogenetic glucosides (*Trifolium repens* contains lotaustralin and linamarin)[4] which produce hydrocyanic acid by hydrolysis with the appropriate enzyme. Again, hydroxylamine has been postulated as an intermediate in nitrogen metabolism by plants and bacteria. The analysis of rumen gases shows 0·1 per cent hydrogen sulphide to be a fairly normal figure, while Dougherty[5] reports the presence of carbon monoxide in concentrations up to 0·17 per cent. Certain plants, especially legumes, are rich in saponin-like substances.

We have already shown that one litre of clover juice (equivalent to about 5 lb. fresh clover) introduced directly into the rumen of a sheep paralysed its movements immediately. After some time, however, the animal showed general symptoms of acute poisoning, namely, dyspnœa, dilatation of the pupils, and finally succumbed in a tetanic convulsion 2 hr. after administration of the juice. The post-mortem findings were consistent with poisoning by hydrocyanic acid. Estimation showed 200 mgm. hydrocyanic acid per litre in the crude clover juice, which is double the lethal dose[6] for sheep of this size (Welsh Mountain, wt. 100 lb.). During the first 90 min., no ruminal movements were recorded; towards the end they were re-appearing again spasmodically but with diminished force (Fig. 2).

In an attempt to produce bloat in the field, three two-year-old Welsh Black cattle (a bullock and two heifers), starved for 12 hr., were turned to graze a white clover pasture. The three animals grazed the clover avidly for 15 min.; the two heifers then stopped, stood listlessly for a while, and then wandered and grazed rough herbage other than the clover, which they deliberately avoided. The bullock persisted with the clover grazing for a further 5-min. period, and then behaved as the heifers had done. Within a period of 30 min. the bullock showed definite

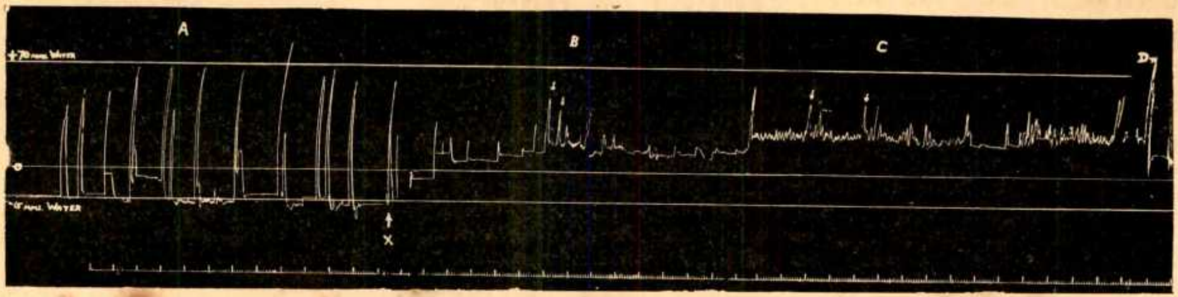

Fig 2. *A*: Normal rumen activity. Drum speed, 5 mm./min.; time marker, 10 per min. *X*: Point of introduction of clover juice (1 litre). *B*: Tracing after addition of the juice. *C*: One hour after dosing, showing rapid respiratory movements and the re-appearance of spasmodic rumen contractions (arrows). *D*: Denotes a marked increase in pressure, when sheep was in a convulsive state

symptoms of distress (respiration 95 per min., pulse 120 per min.) and was slightly blown; the heifers, although full in the flank, were neither blown nor showing signs of discomfort. Blood samples taken at this stage were analysed for hydrocyanic acid content; the bullock's blood contained 0·1 mgm. hydrocyanic acid per 100 ml. blood, while the heifers' had 0·04 mgm. per 100 ml. blood.

The possible role of hydrocyanic acid in the etiology of acute bloat in sheep has been considered before by Clark and Quin[7], but they prefer the 'saponin foam theory' of its pathogenesis (see also Clark[8]).

It seems probable to us that in a complex syndrome like bloat several factors may operate; a satisfactory theory of the cause must not only account for the sequence of symptoms in the animal, but must also explain observations of agriculturists on predisposing environmental conditions. We believe that our findings are significant in this connexion.

We wish to acknowledge our grateful thanks to the Welsh Plant Breeding Station for providing facilities in the field.

DETERMINATION OF ABSOLUTE INTENSITIES OF X-RAY REFLEXIONS FROM RELATIVE INTENSITY DATA

By PROF. S. H. YÜ

Department of Physics, National Tsing-hua University, Peiping

RECENTLY, owing to the advent of various methods[1] of direct determination of phase angles of Bragg reflexions from a crystal, a convenient method of determination of absolute intensities of Bragg reflexions seems urgently needed[2]. In 1942 I proposed a simple method of determination of absolute from relative intensities[3], which has since been made rigorous and so should be reliable in general cases if used properly. Accordingly, I present here the final result of the method, which is applicable to practical cases immediately.

Suppose we have a crystal containing t atoms in the unit cell, the number of shell electrons of the ith atom being Z_i. Let the relative intensities of reflexions for the crystal at room temperature be denoted by $I'(hkl)$ for hkl and $I'(000)$ for 000. We have

$$|F(hkl)|^2 = \frac{F^2(000)}{I'(000)} I'(hkl). \tag{1}$$

We see that if we can determine $I'(000)$ we can deduce $|F(hkl)|^2$ from $I'(hkl)$, for we have the known $F(000) = \sum_{i=1}^{t} Z_i$. Let us introduce

$$\bar{f}(hkl) = \sum_{i=1}^{t} f_i(hkl) \Big/ \sum_{i=1}^{t} Z_i, \tag{2}$$

where $f_i(hkl)$ is the atomic structure factor at room temperature of the ith atom in the cell. If only $f_i(hkl)$ for atoms at rest are available, such as those obtained from James and Brindley's table, suitable temperature correction must be made in order to obtain the room temperature value of $f_i(hkl)$. We further form the sum $\sum_{i=1}^{t} Z_i^2$. Then from the theory of a new X-ray synthesis developed by me, it can be shown that:

$$I'(000) = F^2(000) \frac{\Sigma' U_{n_1h} U_{n_2k} U_{n_3l} I'(hkl)/\bar{f}^2(hkl)}{\sum_{i=1}^{t} Z_i^2 - U_{n_10} U_{n_20} U_{n_30} \cdot F^2(000)}, \tag{3}$$

where Σ' denotes the sum $\sum_{h=-\infty}^{\infty} \sum_{k=-\infty}^{\infty} \sum_{l=-\infty}^{\infty}$, excluding the term of $h = k = l = 0$. U_{nh} are known functions of n and h, the numerical values of which are negligibly small for $h > n/2$; $U_{nh} = U_{n\bar{h}}$ when $\bar{h} = -h$. Thus, if the maximum h, k, l of our available set of $I'(hkl)$ are h_M, k_M, l_M, we may choose $n_1 \doteq 2h_M$, $n_2 \doteq 2k_M$, $n_3 \doteq 2l_M$. The values of U_{nh} for some values of n and h are given below:

$U_{nh} \times 10^4$

n / $\pm h$	48	44	40	36	32	28	24	20	16	12
0	334	364	400	443	498	568	660	790	981	1297

12	209	215	219	220	215	196	87			
13	198	202	204	203	196	181				
14	187	189	189	181	164	73				
15	177	177	174	167	155					
16	166	164	157	142	64					
17	156	152	145	135						
18	144	138	124	57						
19	135	128	120							
20	122	110	51							
21	115	108								
22	99	46								
23	98									
24	42									
ΣU_{nh}	0·9998		1·0010		1·0016		1·0022		1·0037	

The last row gives the sum $\sum_{-h_M/2}^{h_M/2} U_{nh}$ for $n = 48$, 40, 32, 24, 16. Apparently all the sums differ from the theoretical limit $\sum_{h=-\infty}^{\infty} U_{nh} = 1$ only by fractions of 1 per cent, indicating the rapidity of convergence of the infinite series.

The accuracy of $I'(000)$ deduced from (3) depends essentially upon the following four factors:

(1) The accuracy of the observed $I'(hkl)$.

(2) The order of approximation of the equation

$$f_i(hkl) = Z_i \cdot \bar{f}(hkl), \tag{4}$$

which forms the basis of equation (2). The error introduced by the failure of equation (4) is usually not very serious.

(3) The proper correction of the temperature effect in $f_i(hkl)$. If we actually do a suitable experiment to correct this effect, the error introduced is, of course, limited. Otherwise we have to correct the effect with reference to similar crystals of known structures, and

the error resulting in $I'(000)$ may be very large. This uncertain correction of the temperature effect constitutes the chief source of errors in the value deduced for $I'(000)$.

(4) The correct choice of n_1, n_2, n_3. The strict condition is

$$d_m \geqslant \frac{1{\cdot}2a}{n_1}, \frac{1{\cdot}2b}{n_2}, \frac{1{\cdot}2c}{n_3},$$

where d_m denotes the shortest interatomic distance between any two atoms in contact in the crystal. Because this condition is rather too strict to be satisfied easily, let us introduce a much more approximate condition,

$$\begin{aligned} d_a \geqslant\ & 1{\cdot}2 \left\{\left(\frac{a}{n_1}\right)^2 + \left(\frac{b}{n_2}\right)^2 + \frac{2ab}{n_1 n_2}\,|\cos\gamma|\right\}^{1/2}, \\ & 1{\cdot}2 \left\{\left(\frac{b}{n_2}\right)^2 + \left(\frac{c}{n_3}\right)^2 + \frac{2bc}{n_2 n_3}\,|\cos\alpha|\right\}^{1/2}, \\ & 1{\cdot}2 \left\{\left(\frac{a}{n_1}\right)^2 + \left(\frac{c}{n_3}\right)^2 + \frac{2ac}{n_1 n_3}\,|\cos\beta|\right\}^{1/2}, \end{aligned}$$

where d_a denotes the average interatomic distance between any two contact atoms in the crystal: d_a can be roughly estimated from the nature of the atoms contained. In case the structure contains a number of very heavy small atoms, their effect on $I'(000)$ can be estimated.

When all of the foregoing four points have been provided for, it is believed that the error in $I'(000)$ would fall in the range of 5–20 per cent in the usual cases.

To illustrate the use of (3), let us first take a crystal consisting of only one atom at the origin in the unit cell, the number of electrons in the shell of the atom being Z and the atomic structure factor, $f(hkl)$. Then $F(hkl) = f(hkl) = Z\bar{f}(hkl)$. $F^2(000) = Z^2$. If we assume $I'(hkl) = F^2(hkl)$, we have $I'(hkl)/\bar{f}^2(hkl) = Z^2$. Substituting these values in (3) we obtain

$$I'(000) = Z^2\,\frac{\left(\sum\limits_{h=-\infty}^{\infty} U_{n_1h}\right)\left(\sum\limits_{k=-\infty}^{\infty} U_{n_2k}\right)\left(\sum\limits_{l=-\infty}^{\infty} U_{n_3l}\right) - U_{n_10}U_{n_20}U_{n_30}}{1 - U_{n_10}U_{n_20}U_{n_30}}.$$

Using U_{nh} given in the table, with $n_1 = 48$, $n_2 = 32$, $n_3 = 16$, we obtain $I'(000) = 1{\cdot}0051Z^2$, which differs from the assumed $I'(000) = F^2(000) = Z^2$ only by 0·51 per cent. The choice of U_{nh} of any other n_1, n_2, n_3 will give similar results.

Let us next illustrate the method by studying a real crystal, say, *para*dinitrobenzene, the structure of which was determined carefully by James, King and Horrocks[4], who made the determination on the basis of intensities of reflexions $hk0$, $h0l$ and $0kl$. Strictly speaking, we should determine $I'(000)$ from equation (3), based on the relative intensities of the whole set of reflexions hkl. But in the case of the present structure, as we know already from James, King and Horrocks' paper that there is no overlapping of atoms directly upon each other in the projection of the structure in direction b to the ac plane (see ref. 4, Fig. 3), a study of the relative intensities of reflexions $h0l$ is sufficient for our purpose of illustration. Then let us take their observed $F^2(h0l)$ directly as our $I'(h0l)$ and take Robertson's f-values[5] directly as our $\bar{f}(h0l)$. Since no further temperature correction has been made, the values of $\bar{f}(h0l)$ so obtained are under-corrected for the temperature effect as revealed from my studies of the same structure. But we may deliberately use such rough values of $\bar{f}(hkl)$ in order to see if $I'(000)$ so deduced still proves reliable. The structure has

$$F^2(000) = 164^2\,, \quad \sum_{i=1}^{t} Z_i^2 = 1140$$

when the contribution of the hydrogen atoms is neglected. $h_M = 13$ such as in $h0l = 13\ 0\ 1$, and $l_M = 7$ such as in $h0l = 1\ 0\ 7$. Accordingly, we take $n_1 = 24$, $n_3 = 12$. The two-dimensional equation for $I'(000)$ is given by

$$I'(000) = F^2(000)\,\frac{\Sigma' U_{n_1h}\,U_{n_3}\,I'(h0l)/\bar{f}^2(h0l)}{\sum\limits_{i=1}^{t} Z_i^2 - U_{n_10}\,U_{n_30}\,F^2(000)}, \tag{3a}$$

where Σ' denotes $\sum\limits_{h=-\infty}^{\infty}\ \sum\limits_{l=-\infty}^{\infty}$,

excluding the term with $h = l = 0$. Substituting in (3a) the appropriate U_{nh} from the table and the other quantities mentioned above, we obtain $I'(000) = 0{\cdot}85F^2(000)$, differing from the assumed $I'(000) = F^2(000)$ by 15 per cent; an acceptable error obtained by deliberately choosing rather rough values of $\bar{f}(hkl)$.

Details of this work, including the method of correcting for the effect of small heavy atoms, will be presented elsewhere.

FRACTURE OF SOLIDS

A CONFERENCE on "The Fracture of Solids" was held by the British Rheologists' Club on October 29. Prof. N. F. Mott, recently elected president of the Club, opened the conference by pointing out that, quite apart from its practical importance, fracture was the most interesting property of solids to the theoreticians because it is the least understood property, no progress having been made beyond the Griffith crack-theory of 1924. It is not known how cracks exist nor what causes them; experimental work has made clear what happens during fracture, but not how it occurs.

Dr. C. F. Tipper then presented a paper describing some beautiful experimental work on the subject of fracture in mild steel. She divided fracture into three types: the first corresponds to a parting along a shear plane; the second along two intersecting planes, giving a wedge-shaped fracture; and the third along a plane quite different from the shear plane, often at right angles to the principal tensile stress. Iron and mild steel show all three types of fracture, and it is possible to have all in the same test-piece, even in adjacent crystals. The amount of energy absorbed in fracture depends on how much of each type goes to make up the total fracture. The third type, which is generally brittle, can always be traced back to a notch, and so in laboratory experiments a notch is inserted deliberately. The metal at the base of the notch can be regarded as a tensile specimen of very short gauge-length eccentrically loaded, and the natural crack is thus started at 90° to the direction of loading. In a very ductile material the crack eventually turns to 45°, and in a brittle material its mean path remains perpendicular to the direction of loading.

Dr. Tipper showed the importance of inclusions in the metal, separation occurring around such inclusions at an early stage in the deformation and forming a pattern of holes near the actual fracture. This separation divides the material into a bundle of independent test-pieces. Inclusions can also stop a fracture when they lie at right angles to the direction of propagation, as they then relieve the stress. Fracture is thus very strongly structure-sensitive. The main conclusion of this work is that fracture begins piecemeal at different places in the material, a fact confirmed by the work of Bridgman, in which a high hydrostatic pressure is found to increase ductility. In the processes of rolling and wire drawing, cracks are not allowed to open, and this is why such large strains are possible without fracture.

Prof. H. Moore then spoke on the fracture of glass. He pointed out that the phenomena of fracture should be explainable in terms of structure, but that a theory of structure could not be based on a study of fracture alone, as had been attempted by some workers. Vitreous silica consists of SiO_2 tetrahedra linked by the oxygens at the corners, each tetrahedron having four linkages at 120° to each other. In silicate glasses the introduction of an alkali such as sodium oxide breaks these linkages, but divalent oxides, such as lime, can provide bridges between tetrahedra which have become temporarily separated. On the molecular scale the structure is irregular, but on any larger scale it is isotropic, giving rise to the familiar conchoidal type of fracture. The structure has no slip planes, and if strained so that one linkage is broken, the other neighbouring linkages, inclined at 120° to the broken link, are also disrupted. Glass has therefore no ductility, its yield strength being equal to its breaking strength.

As with metals, the strength calculated from the structure is many thousand times greater than the observed strength. Fine freshly drawn glass fibres are, however, many hundred times stronger than massive glass; but the strength diminishes extremely rapidly in moist air. The weakness of glass is in its surface, and can be accounted for by the Griffith surface-flaw theory in combination with the effects produced by adsorbed moisture. Moisture rapidly alters the surface layers and can, in fact, cause the whole of the skin to peel off. Under continuous steady loading in moist air, glass is weaker than under momentary loading, due to progressive deterioration of the side-surfaces of the flaws opened by the deformation. This is not a fatigue effect similar to the fatigue effects in metals; under continually reversed loading, glass shows no sign of fatigue because its structure is not affected by the strain reversals.

Mr. H. Warburton Hall then spoke of the fracture of plastics. The understanding of fracture is likely to be easier in the case of the thermo-plastic types than in the case of the more heterogeneous thermosetting plastics. A large amount of experimental data on the mechanical behaviour of the former have been obtained, including investigations into the dependence of tensile strength on such fundamental properties as molecular weight, molecular weight distribution, chemical structure of the polymer, crystallinity, molecular orientation, time of stressing, etc. Haward found that the time to fail of cellulose acetate under constant stress was independent of any rest or deformation-recovery periods allowed during the test, and depended only on the total time under stress; thus in this case all stressing does irreparable damage.

Mr. Hall described investigations on methyl methacrylate at the Royal Aircraft Establishment which had confirmed that tensile stress combined with solvent vapour absorption caused crazing, and that crazing consists of fractures in the surface of the material. The fractures are local tensile failures which under continued stressing lead to bulk failure. There are, however, two main conditions of the material which influence its tendency to craze. (1) Condition direct from the casting process: the material then contains residual solvent (namely, monomer) and elastic strains. If either the solvent content or the condition of elastic strain is increased, crazing will result. In this case solvent vapour causes random pattern crazing. (2) Heat-treated condition: in this case the residual monomer is fully polymerized, the elastic strains are eliminated and *both* solvent vapour and tensile stress are needed to cause crazing. The craze lines, however, are now always perpendicular to the direction of the tensile stress.

A large number of liquids have been investigated, and all those which swell or dissolve the polymer tend to cause crazing.

Finally, Mr. Hall mentioned that the detailed investigations by E. W. Russell on the solvent-vapour absorption characteristics of methyl methacrylate had indicated the possible mechanism of crazing. His results show that films of the polymer stretched at high temperatures and then cooled to normal temperatures while stretched, absorb vapour more rapidly than films not so stretched. It is likely, therefore, that crazing is due to non-uniform vapour absorption which causes stress relaxation at one point, resulting in stress concentration at others, until local rupture takes place, which appears as crazing.

Dr. E. Orowan spoke on the theory of fracture, pointing out that the Griffith crack-propagation theory gave a very good account of fracture phenomena in glasses. According to the Griffith formula, the strength should be proportional to the square root of the surface energy; according to experiments by Obreimow and himself, the surface energy of mica is about twelve times higher in vacuum than in air, and, if this ratio is assumed for glasses, the strength in vacuum should be about $\sqrt{12}$ (or 3·5) times higher than the strength in air. The same ratio should exist between the fracture stresses for very short and very long durations of the test, because the air cannot penetrate to the tip of the crack in the first case; moreover, there should be no difference between long-time strength and short-time strength if the experiment is carried out in vacuum. All these conclusions have been confirmed experimentally. Dr. Orowan pointed out the geometrical meaning of the two-dimensional fracture criterion put forward by Griffith in 1924. If the two principal stresses P and Q are plotted as ordinates, the criterion of fracture is represented in the plane of P—Q by a curve consisting of a parabola, with vertex at the origin and axes directed at 45° into the negative quadrant, and also of the vertical and horizontal tangents to this parabola. He found that this fracture criterion agrees very well with recent experiments of P. W. Bridgman on the fracture of brittle materials under hydrostatic pressures.

In the discussion Dr. R. N. Haward pointed out that over a time-range of $10^7 : 1$, Preston had found that the relation between log T and $1/S$ (S is breaking strength) is linear, and he doubted whether this would bend over just at the limits which were set by the experimental conditions to give Dr. Orowan's factor of 3·5.

Mr. R. L. Brown spoke on the fracture of coal, where one is interested in the size distribution of the fragmented pieces and also the variation of strength of these pieces with size. He showed that, when the size distribution of broken coal deviates from the natural distribution, some of the particles can be relatively weak, so that further rough handling of the consignment of coal tends to bring them back to the natural size-distribution. This theoretical investigation is confirmed by experimental evidence on one coal. Mr. Brown pointed out that, in the case of coal, one had to think of millions of particles, and it was not possible to consider an individual test-specimen; accordingly, the strength measurements were made by a shatter test, in which the coal was dropped several feet on to an iron plate, and the strength calculated from the resulting degradation.

Dr. W. W. Barkas spoke on the fracture of wood, the oldest structural material. Under tension, wood fractures by the oxygen groups, and the tensile strength accordingly only goes down by 25 per cent when the wood is wet. On the other hand, under compression, wood fractures by shear on the hydroxyl groups, and the compression strength goes down very much more when the wood is wet. In the manufacture of bent-wood furniture, the bending is therefore by kinking on the inside, the outside remaining unbroken. The work due to fracture is almost independent of the moisture content.

M. W. THRING

AMERICAN INSTITUTE OF BIOLOGICAL SCIENCES

IN discussing recent proposals for an Institute of Biology in Great Britain (see *Nature*, December 4, p. 878), reference was made to the recent establishment and activities of the American Institute of Biological Sciences (A.I.B.S.).

During the Second World War, American biologists became acutely conscious of the fact that the importance of biology and the value of the contributions which biologists were making toward the war effort were little understood by the general public and by Government circles in the United States. As a result of this feeling, a movement developed which finally culminated in the establishment of the American Institute of Biological Sciences. After an informal meeting of a few biologists in Cleveland during September 1944 under the leadership of Prof. E. G. Butler, of Princeton University, an open meeting was called in St. Louis in March 1946 under the sponsorship of the Union of American Biological Societies, the American Biological Society, and the American Society of Naturalists. Dr. Detlev W. Bronk put forward the idea of a biological institute, and those present urged that the informal group continue its deliberations. As a result, this group presented plans to the Division of Biology and Agriculture of the National Research Council for the formation of an Institute. An advisory committee, with Prof. H. B. Steinbach as executive secretary, drew up a proposed constitution and by-laws. An organising board, consisting of one representative from each biological society affiliated with the Division of Biology and Agriculture of the National Research Council, met on April 11, 1947, adopted the constitution and by-laws, and presented the plans to the several societies for ratification. It was agreed that when ten societies had given their adherence to the Institute it would be formally organised. This was accomplished by January 1948, and on February 20, 1948, representatives of the adhering societies met in Washington and formally constituted the American Institute of Biological Sciences.

The purpose of the Institute as expressed in its constitution is "the advancement of the biological sciences and their applications to human welfare. To serve these purposes, the Institute will, among other things, assist societies and other organisations in such matters of common concern as can be dealt with most effectively by united action; co-operate with local, national and international organisations concerned with the biological sciences; promote unity and effectiveness of effort among all those who are devoting themselves to the biological sciences and their applications by research, teaching, or by study; and foster the relations of the biological sciences to other sciences, to the arts and industries, and to the public good."

The Institute is set up within the framework of the National Research Council. Several categories of membership are provided: (1) member organisations—societies and other non-profit organisations having a national field of operation in the biological sciences; (2) individual members; (3) affiliates—societies wishing to support the Institute in a less active way than through full membership; (4) associates—commercial or other organisations. The Institute is managed by a governing board, consisting of one representative of each member organisation and four representatives of the National Research Council, with a smaller executive committee. The executive officer is designated as the executive secretary. Member societies make annual grants to the Institute in proportion to their membership. Affiliated societies pay 100 dollars or more, and associates pay a minimum of 200 dollars per year. Headquarters of the Institute are in the National Academy of Sciences, National Research Council Building, 2101 Constitution Avenue, Washington, D.C. The chairman of the board of governors is Dr. Ralph E. Cleland; the vice-chairman, Dr. E. G. Butler; and the executive secretary, Dr. Milton O. Lee. Up to the present, fifteen societies have become full members and two societies affiliated members; they are as follow: American Association of Anatomists, American Physiological Society, American Phytopathological Society, American Society for Horticultural Science, American Society of Ichthyologists and Herpetologists, American Society of Parasitologists, American Society of Plant Physiologists, American Society of Zoologists, Botanical Society of America, Ecological Society of America, Genetics Society of America, Mycological Society of America, Poultry Science Association, Society for the Study of Development and Growth, Society of American Bacteriologists, American Society of Mammalogists, Society of American Foresters.

Since its creation in February 1948, the Institute has undertaken a number of projects. It organised the annual meetings for eleven biological societies which met in Washington during September 1948. It appointed a Committee on Selective Service, which became the Panel of Biology of a committee advisory to General Hershey, director of selective service. This panel has worked with similar panels in other fields to develop a comprehensive plan for selective service which will utilize scientific and technical man-power to the greatest advantage. Recognition and utilization of this Committee marks a definite step forward for biology, this being the first time that biology has been officially recognized in connexion with man-power problems in the United States. The Institute has established a roster of individual biologists who are members of the constituent societies; more than 10,000 individuals are at present listed. A study of publication costs and of possible ways of aiding biological publication is now going on. The Institute is endeavouring to secure increased financial assistance for the American Type Culture Collection, and is developing a plan for a broader and more secure foundation of support for this essential organisation. The publication of a hand-book of biological data is being initiated. The Institute is working with the American Association for the Advancement of Science in the organisation of the meetings of the various biological societies which are to be held in New York during December 1949, and is studying the whole question as to times and meeting-places for future joint meetings of biological societies. A number of other projects are planned for the immediate future and will be undertaken as soon as possible.

The American Institute of Biological Sciences has thus been able to make a distinct contribution to the progress of biology in the few months of its existence.

TETRAETHYL PYROPHOSPHATE AS AN INSECTICIDE

THE shortage of nicotine for use as an insecticide has stimulated the search for suitable substitutes. One of the organic phosphorus insecticides called hexaethyltetraphosphate (H.E.T.P.) seemed to fulfil many of the requirements; but more recent research has indicated that tetraethyl pyrophosphate (T.E.P.P.) is responsible for at least the major part of the insecticidal activity of hexaethyltetraphosphate, and that an insecticide containing a high percentage of this material was desirable. Messrs. Albright and Wilson have now available an insecticide containing 40 per cent tetraethyl pyrophosphate as compared with the 20 per cent contained in so-called hexaethyltetraphosphate. They are issuing a brochure describing the properties of this material and its use as an insecticide.

Tetraethyl pyrophosphate is a mobile liquid, miscible with water and most common organic solvents; it is not, however, freely miscible with petroleum ether or other paraffin hydrocarbons. In the absence of moisture it is a stable compound, but it hydrolyses rapidly in the presence of water. It is hygroscopic. It is said to be compatible with a variety of insecticides and fungicides; but it should not be used with alkaline materials. It may be applied as a spray or as an aerosol. In the concentrations used it exhibits very little phytotoxicity. It lacks the fumigant effect of nicotine. Tetraethyl pyrophosphate is very toxic to warm-blooded animals, and the concentrates must be handled with great care. The products of hydrolysis are said to be harmless, and it would appear that no toxic residues should be present forty-eight hours after spraying, although it seems desirable that a safety margin should be allowed.

Its chief use in practice would appear to be for the control of aphids and thrips, although it may be found useful for other pests; for example, it appears to be effective against the active stages of red spider, although it seems to have little or no ovicidal effect. Another organic phosphorus compound, 0.0.-diethyl 0.-*p*-nitrophenyl thiophosphate, is probably at least as effective an insecticide as tetraethyl pyrophosphate against most of the insect species on which it has been tested, and much more effective against some species. It also acts as an ovicide. This compound, therefore, may prove a serious competitor with tetraethyl pyrophosphate, but it has the disadvantage that, not only is it toxic to warm-blooded animals, but also it is a stable compound and therefore liable to leave dangerous residues. In some circumstances, therefore, tetraethyl pyrophosphate may be the preferable insecticide.

C. POTTER

FORTHCOMING EVENTS

*(Meetings marked with an asterisk * are open to the public)*

Monday, March 7

ROYAL GEOGRAPHICAL SOCIETY (at Kensington Gore, London, S.W.7), at 5.30 p.m.—"Explorations in Western Mexico" (Kodachrome films with commentary by Dr. Telford H. Work).

INSTITUTION OF ELECTRICAL ENGINEERS, SOUTH MIDLAND CENTRE (at the James Watt Memorial Institute, Great Charles Street, Birmingham), at 6 p.m.—Mr. H. E. Dance: "Visual Methods in Engineering Teaching". (To be repeated on Thursday, March 17, at Savoy Place, Victoria Embankment, London, W.C.2, at 5.30 p.m., and on Tuesday, April 5, at the Engineers' Club, Albert Square, Manchester, at 6.15 p.m.)

SOCIETY OF CHEMICAL INDUSTRY (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 6.30 p.m.—Mr. T. Vickerstaff: "The Physical Chemistry of Dyeing".

ROYAL INSTITUTE OF CHEMISTRY, LONDON AND S.E. COUNTIES SECTION (joint meeting with the **WOOLWICH POLYTECHNIC SCIENTIFIC SOCIETY**, at Woolwich Polytechnic, Woolwich, London, S.E.18), at 7.30 p.m.—Dr. G. E. Turfitt: "Science in Criminal Investigations".

Tuesday, March 8

BRITISH PSYCHOLOGICAL SOCIETY, INDUSTRIAL SECTION (in Room 105, London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 1 p.m.—Annual General Meeting; at 1.10 p.m.—Colonel B. Ungerson: "Some Deficiencies in Present-day Industrial Psychology".

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 1.15 p.m.—Prof. Daryll Forde: "The Human Factor behind Food from Africa".*

ROYAL ANTHROPOLOGICAL INSTITUTE (at 21 Bedford Square, London, W.C.1), at 5 p.m.—Prof. W. C. Osman Hill: "Man's Relation to the Apes".

ZOOLOGICAL SOCIETY OF LONDON (at the Zoological Gardens, Regent's Park, London, N.W.8), at 5 p.m.—Scientific Papers.

INSTITUTION OF CHEMICAL ENGINEERS (at the Geological Society, Burlington House, Piccadilly, London, W.1), at 5.30 p.m.—Mr. J. Leyland: "The Application of Vacuum to Industrial Chemical Processes"; Mr. G. Arrowsmith: "The Production of Vacuum for Industrial Chemical Processes".

UNIVERSITY OF LONDON (in the Anatomy Theatre, University College, Gower Street, London, W.C.1), at 5.30 p.m.—Prof. G. Delépine (Lille): "Comparative Stratigraphy of the Carboniferous Marine Formations in N.W. Europe and Mediterranean Area". (Special University Lectures.)* (Further Lecture on March 10.)

UNIVERSITY OF LONDON (at the Institute of Archæology, Inner Circle, Regent's Park, London, N.W.1), at 5.30 p.m.—Dr. J. W. Jackson: "Domesticated Animals from Archæological Sites".*

ILLUMINATING ENGINEERING SOCIETY (at the Lighting Service Bureau, 2 Savoy Hill, London, W.C.2), at 6 p.m.—Mr. W. Harrison: "The Colour of Fluorescent Lamps".

MANCHESTER GEOGRAPHICAL SOCIETY (in the Geographical Hall, St. Mary's Parsonage, Manchester), at 6.30 p.m.—Mr. Harry Vickers: "South German Cities".

INSTITUTION OF THE RUBBER INDUSTRY, BURTON-ON-TRENT SECTION (at the Education Offices, Guild Street, Burton-on-Trent), at 7 p.m.—Mr. H. Willshaw: "Machinery Requirements for the Rubber Industry".

Royal Institute of Chemistry, London and S.E. Counties Section (joint meeting with the **Welwyn Garden City Scientists' Club**, at The Cherry Tree, Welwyn Garden City), at 8 p.m.—Dr. A. Albert: "Drug-Action, Ions and Neutral Molecules".

Institution of Electrical Engineers, Cambridge Radio Group (at the Cavendish Laboratory, Cambridge), at 8.15 p.m.—Prof. D. R. Hartree: "Electronic Calculating Machines".

Wednesday, March 9

Institute of Fuel, North-Western Section (joint meeting with the **National Smoke Abatement Society**, at the Engineers' Club, Albert Square, Manchester), at 2 p.m.—Mr. P. D. Kirkman: "The Efficient Use of Fuel".

Royal Society of Arts (at John Adam Street, Adelphi, London, W.C.2), at 2.30 p.m.—Sir John Forsdyke: "The Functions of a National Museum" (Trueman Wood Lecture). (Further Lectures in the series on Museums will be given on March 23 (Mr. Trenchard Cox: "The Provincial Museum"), March 30 (Mr. Edgar Kaufmann: "Museums and Industrial Design"), April 6 (Mr. A. S. Edwards: "The Local Museum"), April 27 (Dr. Iorwerth C. Peate: "The Folk Museum"), May 11 (Mr. Elias Svedberg: "Museum Display"), and on May 25 (Dr. D. A. Allan: "Museums and Education").)

Linnean Society of London (at the British Museum (Natural History), Cromwell Road, London, S.W.7), at 3 p.m.—Demonstration: "Zoological Taxonomy after 1758".

Society of Public Analysts and other Analytical Chemists (at the Royal Society, Burlington House, Piccadilly, London, W.1), at 3.30 p.m.—Annual General Meeting.

Society of Chemical Industry, Microbiological Panel of the **Food Group** (at the Medical Society of London, 11 Chandos Street, Cavendish Square, London, W.1), at 6.15 p.m.—Annual General Meeting; at 6.30 p.m.—Dr. E. Windle Taylor: "Microbiological Problems in the Production of Pure Water".

Scientific Film Association (in the Lecture Theatre, Wellcome Foundation, 183 Euston Road, London, N.W.1), at 7 p.m.—Miss F. Anthony: "The Organisation of a Research Film Unit".

Institution of the Rubber Industry, Southern Section (at the Polygon Hotel, Southampton), at 7.15 p.m.—Mr. H. J. Lanning: "Neoprene".

Society of Instrument Technology, North-West Section (at the College of Technology, Manchester), at 7.30 p.m.—Mr. G. A. R. Foster: "Some Automatic Testing Instruments for the Measurement of the Regularity of Cotton Yarns and Rovings".

Thursday, March 10

Royal Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Sir Charles Harington, F.R.S.: "National Institute for Medical Research".

University of London (in the Physiology Theatre, University College, Gower Street, London, W.C.1), at 4.45 p.m.—Dr. C. E. Dent: "The Development and Application of Paper Chromatography".* (Further Lecture on March 17.)

Linnean Society of London (joint meeting with the **Systematics Association**, at Burlington House, Piccadilly, London, W.1), at 5 p.m.—Discussion on "Cytology as a Factor in Taxonomy" (to be opened by Dr. W. B. Turrill).

Royal Statistical Society, Research Section (at the London School of Hygiene and Tropical Medicine, Keppel Street, London, W.C.1), at 5.15 p.m.—Mr. G. A. Barnard: "Statistical Inference".

Illuminating Engineering Society, Manchester Centre (in the Reynolds Hall, College of Technology, Manchester), at 6 p.m.—Mr. W. E. Harper and Mr. H. P. Walker: "Acrylic Plastics in Lighting".

Institute of Welding (joint meeting with the **Institution of Structural Engineers**, 11 Upper Belgrave Street, London, S.W.1), at 6 p.m.—Mr. J. T. Phillips and Mr. F. J. Daniels: "Welded Steel Framed Buildings".

Society of Chemical Industry (joint meeting of the **Nottingham Section** and the **Fine Chemicals Group**, at the Gas Company's Show Room, Parliament Street, Nottingham), at 6.30 p.m.—Mr. J. C. McGowan and Mr. J. F. Grove: "Some Applications of Physical Chemistry to the Study of certain Biologically Active Compounds".

British Association of Chemists (at Gas Industries House, 1 Grosvenor Place, London, S.W.1), at 7 p.m.—Dr. Joseph Needham, F.R.S.: "The Work of U.N.E.S.C.O.".*

University of London (at Wye College, Wye, Kent).—Sir John Russell, F.R.S.: "Agricultural Research in the 20th Century" (Fellowship Lecture).*

Friday, March 11

Royal Astronomical Society (at Burlington House, Piccadilly, London, W.1), at 4.30 p.m.—Scientific Papers.

Physical Society (in the Science Museum, Exhibition Road, London, S.W.7), at 5 p.m.—Scientific Papers. (Members of the Colour Group are invited.)

Society of Public Analysts and other Analytical Chemists, Physical Methods Group (in the Chemistry Lecture Theatre, Imperial College of Science and Technology, Imperial Institute Road, London, S.W.7), at 5.30 p.m.—Discussion on "Polarographic Analysis".

University of London (in the Geology Lecture Theatre, Royal School of Mines, Imperial College of Science and Technology, South Kensington, London, S.W.7), at 5.30 p.m.—Prof. F. T. Brooks: "The Contribution of the Plant Pathologist to Horticulture".*

Institution of Electrical Engineers, Education Discussion Circle (at Savoy Place, Victoria Embankment, London, W.C.2), at 6 p.m.—Discussion on "The Application of Flux Meters to Experiments on Electric Machines" (to be opened by Prof. E. B. Moullin).

North-East Coast Institution of Engineers and Shipbuilders (at the Mining Institute, Newcastle-upon-Tyne), at 6.15 p.m.—Mr. R. W. L. Gawn: "Cavitation of Screw Propellers".

Institution of Structural Engineers, Lancashire and Cheshire Branch (at the College of Technology, Manchester), at 7 p.m.—Mr. G. R. Hinks: "Building the Central Library and Town Hall Extensions, Manchester".

Saturday, March 12

Institution of Chemical Engineers, North-Western Branch (in the Reynolds Hall, College of Technology, Manchester), at 3 p.m.—Mr. J. C. Wood-Mallock: "Solvent Extraction as a Unit Process".

APPOINTMENTS VACANT

Applications are invited for the following appointments on or before the dates mentioned:

Assistant Agricultural Economist in the Department of Agriculture—The Registrar, The University, Leeds 2 (March 10).

Senior Scientific Officer (with a degree in science with first-class honours in botany) and a **Senior Experimental Officer** (with at least the H.S.C. in a science subject or equivalent qualification and a good knowledge of crops and crop husbandry), at the Department of Agriculture for Scotland Seed Testing and Plant Registration Station at East Craigs, Corstorphine, Edinburgh—The Secretary, Civil Service Commission, Scientific Branch, 27 Grosvenor Square, London, W.1, quoting No. 2434 (March 10).

Assistant Experimental Officers (3, temporary), Food Infestation Control, Department of Agriculture for Scotland—The Secretary, Ministry of Labour and National Service, Technical and Scientific Register (K), York House, Kingsway, London, W.C.2, quoting G.536/48 (March 10).

Deputy Statistical Officer in the Statistical Section of the Town Clerk's Department—The Town Clerk, Room 30B, Council House, Birmingham 1, endorsed 'Deputy Statistical Officer' (March 11).

Lecturer in Chemical Engineering—The Clerk to the Governing Body, Battersea Polytechnic, Battersea, London, S.W.11 (March 12).

Research Manager—The Director, Motor Industry Research Association, Great West Road, Brentford, Middx. (March 12).

Lecturer (Grade III) **in Chemistry**, with special interest in physical and inorganic chemistry—The Registrar, Queen Mary College, Mile End Road, London, E.1 (March 14).

Junior Assistant Physicist in the Physics Department—The Secretary, Bristol Royal Hospital, General Hospital Branch, Guinea Street, Bristol 1 (March 15).

Geological and Topographical Draughtsmen in the Department of the Geological Survey of Southern Rhodesia—The Secretary, Rhodesia House, 429 Strand, London, W.C.2 (March 15).

Lecturers (2, Grade II) **in Mining**—The Secretary, The University, Birmingham 3 (March 19).

Readership in Theoretical Physics at Queen Mary College—The Academic Registrar, University of London, Senate House, London, W.C.1 (March 21).

Robert Blair Fellowships in Applied Science and Technology—The Education Officer (H.1/2), County Hall, Westminster Bridge, London, S.E.1 (April 1).

Visiting Professor of Plant Physiology at the Faculty of Science, Farouk I University, Alexandria—The Director, Egyptian Education Bureau, 4 Chesterfield Gardens, London, W.1 (April 15).

Senior Technician with histological training for laboratory principally engaged in endocrinological research—Professor of Anatomy, Medical School, Edgbaston, Birmingham 15.

Laboratory Technicians—The Regional Blood Transfusion Officer, Bridle Path, York Road, Seacroft, Leeds.

Senior Technician in the Department of Materia Medica—The Administrative Officer, Medical School, Dundee.

Laboratory Assistant to help in sorting and mounting entomological material—The Secretary, Department of Entomology and Parasitology, School of Tropical Medicine, Liverpool 1.

Physicist or **Engineer** to develop various special components of the cyclotron, and a **Vacuum Engineer**—The Director, Radiotherapeutic Research Unit, Hammersmith Hospital, Ducane Road, London, W.12, endorsed 'Cyclotron'.

Experimental Officers (2) to assist in studies of Bee behaviour—The Secretary, Rothamsted Experimental Station, Harpenden, Herts.

Research Physicist for fundamental research on Atmospheric Physics—Dr. G. B. B. M. Sutherland, Pembroke College, Cambridge.

Technician (Grade III) as second Lecture Theatre Assistant in the Department of Physics (Ref. Physics/2), and a **Technician** (Grade IV) in the Department of Geology (Ref. Geology/2)—The Secretary, University College, Gower Street, London, W.C.1, quoting the appropriate Ref.

Entomologists (2) in the Research Division of the Department of Agriculture and Forests, Sudan Government—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Agricultural Entomologist'.

Inspector (Plant Protection) **in the Research Division** of the Department of Agriculture and Forests, Sudan Government—The Sudan Agent in London, Wellington House, Buckingham Gate, London, S.W.1, endorsed 'Plant Protection'.

Lecturer or Assistant Lecturer in Mathematics—The Registrar, University College, Exeter.

Surveyors (experienced and qualified) in the Survey Department of Hong Kong, Malaya, Nigeria, the Gold Coast and Tanganyika—The Director of Recruitment, Colonial Service, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Physicist, a **Chemist**, and an **Engineer**, for a new laboratory at Galashiels—The Secretary, Wool Industries Research Association, Torridon, Leeds 6.

Field Zoologist in the Veterinary Department, Kenya, for Tsetse Fly survey and control—The Director of Recruitment, Colonial Service, Colonial Office, Sanctuary Buildings, Great Smith Street, London, S.W.1.

Lecturer in General Science with particular application to foodstuffs, and a **Lecturer in Foodstuffs** with experience in nutrition and microbiology—The Principal, Borough Polytechnic, Borough Road, London, S.E.1.
